INDEX OF CONTENTS.

JANUARY TO JUNE, 1898.

A

ABBOTSBURY, early flowers from, 127
Aberdeen, a botanic garden for, 250
Abnormal *Cattleya Trianaei*, plumosa, 94
Abutilon insigne, 229
Acæna glabra, 28
Acænas, 45
Acanthosonchus spinosus, 28
Aceras Bolleana, 36
Acidantha tubulosa, 318
Acokanthera spectabilis, 293
Acrophyllum venosum, 316
Adaptation, the origin of species by,

228
University, 25

Albica prolifera, 396
Allotments, at Eynsford, 128; in the county of Surrey, 26

Aloe concinna, 226; *A. Schweinfurthi*, 227
....., the, 28, 50, 89, 111, 113, 283, 322

Alsine juniperina, 28
Alströmarias, 205, 220, 237, 244; as pot plants, 187

Amateur gardeners, 216
America, Potatoes in, 142
American Cowslips, new varieties of, 317

American Notes, 31, 52, 95, 202, 326
Amonium hemisphoricum, 312

Analysis, ash, and the manuring of plants, 322

Androsace lanuginosa, 112

Anemone blanda atro-cerulea, 140; *A. fulgens* and *A. hortensis*, sowing seeds of, 356; *A. japonica* Queen Charlotte, 234; *A. rubra*, 28

Angræcum leonis, 306

Annuals, spring-flowering, pot, 299

Anoanthus breviflorus, 79

Anthracite coal burnt in grates, 12

Antigua, the Sugar-cane industry in, 371

Antirrhinum glutinosum, 28

Apiary, the, 55, 183, 215, 279, 311, 343, 377

Apogamy, and the development of sporangia upon Fern prothalli, 201

Apple, a twin, 174; Blenheim Orange, 205; at Ruxley Lodge, 117; blossom, the ornamental qualities of, 391; Borsdorf Reinette of Doberan, 70; crop of Tasmanian, 109; culture, some causes of failure in, 257; Dumelow's seedling, 141, 157; Gascoigne's Scarlet, 221, 236; Gloria Mundi and others, 286; Newton Wonder, 221; Lord Sudeley, 221; Royal George, 129, 142, 172, 204, 236; Royal Snow, 11, 28; the Gooseberry-, 157

Apple and Pear-tree pruning, 13, 30, 45, 60, 74, 104

Apple-trees, the growth of, 59

Apple, cold storage of, and other fruits, 377; from Nova Scotia, 202; late-keeping dessert, 156; seedling, 145; valuable late, 116; why not plant them according to affinity of blossom? 391

Aquilegia formosa, 28

Araucaria imbricata, 188; ripening seed at Petworth, 205

Arbutus Menziesii, 373
Arctotis virgata, 308, 348
Aristida setacea forming a ball, to obtain seed-dispersion by wind, 211
Arthropodium cirratum, 235
Artichoke, the White Jerusalem, 171; Globe, constant bearing of Lombardy, 221

Arum, a two-spated, 119

Arums, two and three-spated, 174

Ash analysis, and the manuring of plants, 322

Asparagus, the cultivated species of, 122, 147, 178; *A. comorensis*, 179

Asparagus industry, the French, 225, 283

Asphodeline, the genus, 111

Asplenium nidus var. *multilobatum*, 20

Aster Amellus, 28

Asters, French, 165

Astrantia major rosea, 50

Auricula Abbé Listz, 285; *A. Snow-drop*, 330; *A.*, the Yellow Dundee, 375

Awards, the, of the Royal Horticultural Society, 115, 129, 141, 171

Ayrshire, market-gardening at Loans, 392

Azalea indica out-of-doors at Clyne Castle, Swansea, 392; *A. linearifolia* in Belgium, 258

Azores, the botany of the, 133

B

BALTET, C., Russian decoration for, 115

Banks, Sir Joseph, the portraits of, 140

Barberry and Wheat mildew, 45

Baron's Holt, Twickenham, Orchids at, 306

Bauhinia variegata, 178

Beans, canker in French, 293

Beech, edible fungus on, 62

Bees, early swarming of, 91; in a block of stone, 91

Begonias, diseased leaves, 318, 398; giant fringed, 234

Belfast Botanical Gardens, the, 50

Belgium, notes from, 128, 290

Belgrove, notes from, 316

Belvoir Castle, the mildness of the season at, 130

Benefit and Provident Society, United Horticultural, 30

Benevolent Institution, Gardeners' Royal, 29, 58, 70, 73, 89, 126, 141, 157, 172, 205, 234; annual dinner, 367; Victorian Era Fund, 219

Devon and Exeter auxiliary of the, 399; Worcester branch of the, 10

Bersaba, notes of the district of, 364

BOOKS, NOTICES OF:—A Flower-hunter in Queensland and New Zealand (*Mrs. Rowan*), 140; Aquatic and Bog Plants (*Wilh. Mönkemeyer*), 10; Botanical Magazine, 42, 102, 152, 233, 312, 380; Botanical Observations (*Dr. Trelease*), 133; British Flora (*Rev. E. F. Linton*) (announced), 154; Cobbett's English Gardener, 209; Die Sumpf und Was erpflanzen,

Ihre Beschreibung, Kultur und Verwendung (*Wilh. Mönkemeyer*), 10; Flowers of the Field (*Johns*), new ed. (announced), 152; Flora of Tropical Africa, Rejuvenescence of, 10; Flora of Tropical Africa, 281; Flora Pyrenæa per ordines Naturales gradatim digesta, vol. i. (*O. Penzig*), 11; Flower Favourites: their legends, symbolism, and significance (*Lizzie Deas*), 313; Garden Notes for the Colonies and Abroad (*James Carter & Co.*), 69; Herbals, Early, 133; Home Gardening (*W. D. Drury*), 297; Hooker's *Icones Plantarum*, 346; *Icones Bogorienses*, 154; Journal of Kew Guild, 378; Kalendarium Hortense (*Evelyn's*, published in 1664), 187; Kew Bulletin, 115, 126, 297, 380; La Maison Rustique (*Carolus Stephanos and Dr. Chas. Stevens*), 229, 275, 325; La Question de la Protection des Oiseaux en Europe, 154; La Semaine Horticole, 115; Les Végétaux et les Milieux Cosmiques (*M. J. Constantine*), 152; Nature Notes, 169; Osbeck's China, 241; Palmenzucht und Palmenflege (Propagation and Cultivation of Palms), (*Dr. Udo Dammer*), 77; Publications Received, 11, 26, 58, 71, 102, 115, 140, 154, 219, 250, 267, 282, 329, 363, 380, 395; Report of the Michigan Board of Agriculture, 394; Revisio Specierum Generis *Cratægi* imprimis earum quæ in Hortus Daniæ coluntur (*Hawthorns*), (*J. Lange*), 261; Rosarian's Year-Book, 42; The Advertisers' A B C, 58; The Australian Kitchen Garden (*Frank Finedon*), 86; The Cactus Journal, 169; The Chemistry of the Garden (*Herbert Cousins*), 153; The Culture of Vegetables and Flowers from Seeds and Roots (*Sutton & Sons, Reading*), 71; The Culture of Vegetables for Prizes, Pleasure, and Profit (*Toogood*), 380; The Fern Bulletin, 250; The Flora of Berkshire (*G. C. Druce, M. A.*), 155; The Flora of the Azores (*Dr. Trelease*), 133; The Fruit Growers' Annual, 344; The Genus *Cyclamen* (*Dr. F. Hildebrand*), 169; The Illustrated Bouquet, 282; The New Flora Britannica, 340; The Origin of Plant Structures by Self-adaptation to the Environment, 307; The Rose Garden (Supplement), (*W. Paul*), 169; The Silva of N. America (*Prof. Sargent*), 378; Toogood's Treatise on Pastures and Pasture Plants, 380; Transactions of the New Zealand Institute, 321; Treatise on Pastures and Pasture Plants (*W. Toogood*), 169; Who's Who, 216

Boron food-preservatives, 395
Borenia megastigma, 293
Botanical discoveries, recent, in New Zealand, 321; gardens, Belfast, the, 50
Botany in schools, 328
Bougainvillea glabra at Moatlands, Paddock Wood, 168
Bouquets, water, 105

Broccoli, fasciated, 139; sprouting, 173; white, 316
Bulb garden, the, 4, 392
Bulb-mite, preventions and cures for, 396
Bulbs, relative merit of, 362

C

CABBAGE, pitcher on leaf of, 394
Cabbages for market growing, 124
Cairo, the Ezbekieh Park at, 26
Caladenia alba, 140
Calanthe Veitchi, 116; abnormal flowering of, 104
Calanthe Veitchi splendens at Weston-birt, 33

Calcutta, Royal Botanic Gardens, 43; appointment of surgeon-major D. Prain as superintendent of, 267

Callicarpa purpurea, 30

Callis Court, Peach and Nectarine trees at, 116

Calochortus Purdeyi, 394

Calypso borealis, 227

Camellias out-of-doors, 373, 396

Campanula mirabilis, 50

Canker in Cocoa, 344; in French Beans, 293

Cannamois virgata, 308

Cannas in Stuttgart, 80; the Italian or Orchid-flowering, 2

Cantua dependens, 136

Cape, fruit from the, 185; orchards and vineyards at the, 219

Cape Town, a view in Mr. Arderne's garden at, 233

Carnations, disease of, 200; Queen of the Fancies, 375; Harrow Weald Beauty, 349; manuring and wire-worms, 382

Carnations and caterpillars, 119

Carne, near Penzance, 298

Carnivorous slugs, 12

Carrots, early, 82

Cartridge, artificial manure, 264

Caryota urens, the home of, 193

Catasetum splendens × var. *Grignani*, 94

Cattleya, William, 116

Cattleya, a malformed, 362; *C. aurea*, 94; *C. candida*, 78; *C. × Cecilia*, 226; *C. citrina*, 306; *C. Hardyana* × var. *Fanyauiana*, 94; *C. × var. Regina*, 226; *C. Mendeli*, Empress Queen, 226; *C. Trianaei* var. *albida*, 161; *C. Broome's* var., 134; *C. Chardwar* var., 134; *C. varieties*, 148

Cattleyas, and other Orchids, the cultivation of, 268; a paper on the cultivation of, 195; the culture of, 210

Ceara Rubber, 344

Cedrus Deodara, varieties of, 229

Celandine, the growth of the, 267

Celastrus articulatus, 28

Celeriac, 82

Cereal, Soudanese, 232

Cereals, the mildews of, 232

Ceylon, botanic gardens, tea, coffee, rubber, &c., at, 260

Ceylon, rubber cultivation in, 221

Charities, gardeners, and their wages, 298, 383, 397; canvassing in the garden, 104

Cheam Park, Orchids at, 389
 Chimonanthus fragrans, 94
 "China" steamship, wreck of the, 201
 Chiswick gardens, the, of the Royal Horticultural Society, 282
 Chorizemas, the, 364
 Chrysanthemum, a gigantic trained, as grown in the imperial gardens, Tokio, 139
 Chrysanthemums, market, 20; C. maximum Daviesi, 329; C. Princess Blanche as a late flower, 165; notes on the cultivation of, 5; novelties in, 96, 116; too-much-alike, 278
 Chrysanthemum Society, the National, 138; a National, in Italy, 281
 Cinchona in India, the, 162, 180
 Cineraria hybrids, 318
 Cirsium candidissimum, 161
 Clare Lawn, Orchids at, 273
 Clematis calycina, 78; C. heracleifolia, 50
 Clip, pot-suspending, a, 105
 Cliveias, propagation of, 356
 Clover and Grass seed crops, 27
 Clyne Castle, Azalea indica out-of-doors at, 392; Peaches at, 397
 Cobbett's English Gardener, 209
 Cobaea scandens foliis marmoratis, 234
 Cocoa, canker in, 344
 Cocus Weddelliana, Hort., what is, 221
 Coelogyne cristata, 139
 Coffea stenophylla, the merits of, 362
 Coffee-growing in Queensland, 323
 Colchicum cilicicum, 34; C. libanoticum, 140
 Coleus thyrsoides, 79
 Colonial Notes, 30, 186, 221, 260, 323, 371
 Colour in Daffodils, 236
 Combe Abbey, treatment of a swamp at, 277
 Commons, the protection of, 363
 Conifer forests, new species of trees succeeding, 157
 Conifers at Melton Constable, 212
 Continental novelties, 221
 Convallaria Fortini, 149
 Coombe House, Croydon, a fine plant of Dendrobium nobile at, 340
 Coprosma Pehei, 50
 Coriaria terminalis, 110
 Corms and bulbs, the propagation of, 164, 371
 Cornish garden, a little, 33, 93, 148, 196, 273, 353
 Cornus mas, 78
 Corokia Cotoneaster, 50
 Cotoneaster, a monograph of, 167
 Cotton, Central African, a, 300
 Cotton-plant, a new, 96
 Cotula squalida, 50
 Courtlands, near Penzance, 363
 Crassula columnaris, 66
 Crocus zonatus, 85
 Crocus, the, in the spring-garden, 172
 Crocuses and sparrows, 187
 Crops, suggestions for the manuring of various, 346
 Cucumber "Every-day," 216
 Cultivator, a revolving, 73
 Culture of Cattleyas, the, 195
 Culture and variation, 307, 347
 Curcuma Roscoeana, 197
 Currant, a golden-leaved, 383
 Currant bud-mite, the, 119
 Cuttings, raising, 280, 348
 Cyclamen, a sportive, 2:6, 299
 Cyclamen cilicicum, 81
 Cyclamen development, 173
 Cyclamen persicum giganteum, 156
 Cyclamen persicum—What is it?, 45
 Cyclamens, various modifications in the flowers of, 134
 Cymbidium pendulum, 226
 Cypress, diseased, 174
 Cyripedium Beeckmanni x L. Linden, 94; C. Crawshayae, 18; C. insigne var. citrina, 94; C. i. var. Janus, 94; C. i. var. Sanderæ, 15, 30
 Cyripedium, monstrous, a, 14
 Cyripediums with fungus, 119
 Cyrtosperma Afzelii, 226
 Cytisus Adami, 398; C. Andreanus x, 300; C. Ardoini, 289; C. proli-ferous, 142

D

DAFFODILS, colour in, 236; in relation to the soil, 172; the green colour in, 104
 Dahlia, an old treatise on the, 116; D. Charlotte Deegen, 234
 Dahlia Society's selected list of "Cactus" varieties, 10
 Damping-off of Cauliflowers and Stocks, 366; of cuttings, 280; of seedlings and cuttings, 360
 Daphne Mezereum, 94
 Date-Palm in Bussorah, the, 380; in India, the, 4
 Datura suaveolens, as cultivated at Thelwall Heys, 70
 Dendrobium nobile, at The Cedars, Harrow Weald, 338; at Coombe House, Croydon, a fine specimen of, 340; a fine plant of, 161; varieties, 112; a variegated-leaved, 299, 316
 Dendrochilum filiforme, 274
 Deutzia corymbiflora, 121
 Devon, a south, garden, 330
 Diacrium bicornutum, 178
 Dianthus Boissieri, 50; D. diutinus, 50; D. gracilis, 50; D. graniticus, 50; D. microlepis, 50; D. pinifolius, 50; D. spinosus, 50; annual, 329
 Dickson, Mr. Hugh, presentation to, 44
 Didiera mirabilis, 110, 308
 Diospyros Kaki, 14, 59
 Dipladenias, the cultivation of, 186
 Diseased Pinus monticola, 244
 Diseases of Carnations, the, 200
 Divis maculata, 161
 Dodecatheon, new hybrids of, 317
 D'Ombra, Rev. H. H., presentation to, 297
 Dorstenia arabica, 354
 Dover House Gardens, Roehampton, 348
 Downes, The, Hayle, 219
 Draba repens, 170; D. tridentata, 170
 Dracæna thalioidea, 140
 Drummond & Sons, Stirling, fire at the premises of, 346
 Dryandra calophylla, 308

E

EARNOCK Hall, Hamilton, N.B., 62
 Eclipse expedition, a botanist with the, 161
 Edinburgh, lectures on landscape gardening in, 198
 Edinburgh Botanic Gardens, 222, 318
 Edwards, Sydenham Teast, 340
 Egg-plant, the, 105
 Eichornia speciosa, 300
 Elmhurst, Reading, 342
 Engelmann Cañon, Colorado, 201, 347
 Epacris, 166
 Epi-Cattleya x radiato-Bowringiana, 391
 Epidendrum nocturnum, 227
 Epilobium luteum, 170
 Eranthis cilicicus, 140
 Erica lusitanica, 144; E. Mediterranean hybrida, 6, 78
 Erigeron compositus, 170
 Eriostemons, the culture of, 290
 Eritrichum nanum, 346
 Erodium cheilanthifolium, 170; E. chrysanthum, 283; E. daucoides and E. olympicum, 171
 Eryngium glaciale, 283
 Erysimum thyrsoides, 283
 Essex technical laboratories, work at the, 362
 Eucalyptus globulus in flower at Bishop's Teignton, 346
 Eucryphia pinnatifolia, 15
 Eulophiella Elisabethæ, 178; E. Peetersiana flowering at Burford Lodge, 201
 Euonymus in the Isle of Wight, 60
 Evelyn's times, and now, 186
 Evolution Committee of the Royal Society, 119
 Exeter pleasure-grounds, improvement of, 313
 Experiments, report of field at Reading University Extension College, 346
 Eynsford, allotments at, 128

F

FALCARIA scioides, 283
 Faquet, M., retirement of, from the Jardin des Plantes, 184
 Fasciated Broccoli, 139
 Fatsia japonica, 6
 Feeding of plants, 264
 Felicia echinata, 308
 Ferments in plants, 312
 Fern, the crested birds-nest, 20
 Fern-variations, pouch-bearing, and other, 211
 Fernery, the, 155, 163, 290
 Ferns, hardy, 155, 163, 290
 Ferns, in America, 31; of Nicaragua, the, 169
 Ferraria antherosa, 318
 Ferula asafoetida and F. Narthex, 283
 Finger-and-toe disease on Swedes and Turnips, 281
 Fish-refuse as manure, 129, 142
 Fish River, notes of the district of the, 315, 364
 Flax produce in Ireland, 15, 139
 Flora, the, of arid regions, 175
 Floral device, political, in U.S.A., 281
 Florists' flowers, 5, 96, 165, 181, 230, 278, 375
 "Flourishing," 391
 Flower garden, the, 7, 22, 39, 54, 69, 82, 99, 112, 125, 136, 151, 166, 182, 199, 214, 231, 246, 263, 295, 310, 327, 342, 359, 376, 393
 Flowering plants for Easter decoration, 228
 Flowers, cultivation of, in the open, 156; for cutting, hardy plants for furnishing, 205, 299; from the Riviera, not to be sent by sample post, 267
 Food-preservatives, boron, 395
 Forcing-house, heating of, 52
 Forcing Tomatoes, 6
 Foreign correspondence, 80, 103, 314
 Forestry, 97, 212, 350, 358
 Forest school, a, for the U.S.A., 272
 Forests of Siam, a tree in the, which causes irritation, 85
 Forests, working plans for, 150
 Forsythia, a European, 71
 Fountains, miniature, 198
 France, the table Grape industry in, 109
 Freesia bulbs, arrested growth in, 318
 Freesias, 117, 130, 142, 205; more about, 104; the cultivation of, 4
 French Asparagus industry, the, 225, 283
 French garden, a, in 1545, 12, 26
 Frost damage in America, 326
 Frost on June 15, at Belvoir, 397
 Fruit crops in East Kent, 384
 Fruit, from Australia, 281; the Cape, 154, 201; judging, 12, 30, 61, 90; prospects, the, 300
 Fruit show, the coming, at the Crystal Palace, 360, 382
 Fruit trade, the, lecture by Mr. Garcia on, 30
 Fruit-tree labels, 60
 Fruit-trees, evaporation from, 337; researches in pruning, 289; the effects of the summers 1896-97 on, 88; the pruning of, 116; the weather and the, 24
 Fruits under glass, 7, 22, 39, 54, 68, 83, 99, 112, 124, 136, 151, 166, 183, 198, 215, 230, 247, 262, 279, 294, 311, 326, 343, 358, 377, 392
 Fry, Geo., 87
 Fuels, the working value of, 324
 Fungus, edible, on Beech, 62
 Fungus on Orchid roots, 206
 Furcraea gigantea var., 227

G

GALANTHUS cilicicus, 79; G. grandiflorus, 116; G. Ikarie, 140
 Galium tyrolense, 284
 Garden and Forest, suspension of, 26, 52

Garden, a French, in 1545, 12, 26
 Garden pictures and landscapes at New Gallery, 260
 Gardener, what is expected of a, 362
 Gardeners' charities and gardeners' wages, 298, 348
 Gardeners' self-help, 367
 Gardenia Devoniana, 22
 Gardenias, culture of, 134, 157, 178, 182
 Gardenias grandiflora and radicans, 197
 Gazanias, 210
 Genista horrida, 234
 Gentiana Favratii, 284; G. pyrenaica and G. Rostani, 284
 Geraniums Traversii and sessiliflora, 284
 Germany, notes from, 201
 Germination of seeds, 354
 Geum speciosum, 284
 Ghent Quinquennial Exhibition, 24, 216, 248, 251, 297, 316
 Ghent, the coming exhibitions at, 24
 reminiscences of, 276, 290, 308
 Gladiolus, for late-flowering in pots, 197; origin of G. gandavensis, 170
 Gladstone, Mr. W. E., and Clumber, 344; favourite flower, 380
 Glass-house, a tropical, in Trinidad, 163
 Globularia cordifolia alba, 284
 Gloeosporium Lindemuthianum (French Bean Canker), 293
 Gooseberry mildews, prevention of, 203, 233
 Gourds, 105
 Graft hybridisation, 395
 Grafting, a mixed method of, 84; the effects of, upon the Grape-vine, 365, 397; the principles and practice of, 356, 372; with a strip of bark carried over the end of stock, 286
 Grape, Madresfield Court, 117; Gros Colmar, 130
 Grape, the table, industry in France, 109
 Gray, J., presentation to Mr., 346
 Greenwich Park, the grounds of the Ranger's Lodge at, opened to the public use, 346
 Grevillea fasciculata, 308
 Griselinia littoralis, 367; flowering in Dorsetshire, 299
 Gunnersbury House gardens, 314
 Gunnersbury Park, Vanda teres at, 78; gardens at, 282

H

HALL for horticulture, a, 14, 29, 45, 60, 73, 90
 Hamamelis or Witch Hazel, 45
 Hammock, how to sling, 294
 Hampstead Heath, tree-planting, 128
 Hardy flowering plants, 236
 Hardy fruit garden, the, 6, 23, 38, 55, 67, 83, 98, 113, 124, 137, 150, 167, 182, 199, 214, 230, 247, 262, 279, 310, 326, 343, 358, 377, 393
 Hardy plants for furnishing flowers for cutting, 188, 299
 Hatfield, Strawberries at, 338
 Heating forcing-houses, 52
 Hellebores, diseased, 14
 Hen's freak, a, 316
 Heracleum Mantegaffianum, 284
 Herbaceous border, the, 323
 Herbals, early, 133
 Heuchera sanguinea, 323
 Hildesheim, the Rose of, 154
 Himalayan Rhododendrons, 65, 80
 Hippeastrums, 220
 Holkham, 87
 Holboellia latifolia, 383
 Holly with red and yellow berries, 15
 Hollyhock, a fringed, 229
 Hollyhock, the, 230
 Hooker, Sir William and Sir Joseph, 361
 Horse-Chestnut, the, second flowering of, 228
 Horticultural College, Swanley, report of the, 169
 Horticultural training at Kew, 56

Hose, garden-, an improved, 281
Howard, presentation to Mr. W., 312
Huernia somalica, 354
Hyacinth, variation of colour in a, 170
Hyacinths, relative merit of varieties of, 362; a selection of fifty varieties of, 258; useless multiplication of names in, 157
Hyde Park, the floral display in, 249
Hymenophyllum rufescens, 79

I

IBERIS Bernardiana and I. Gartonii, 284; I. stylata, 237
India, gardening under difficulties in, 4; the Cinchona in, 162, 180; the Date Palm in, 4
India-rubber, sources of commercial, 255
Insects, the present plague of, 384
Ireland, the growth of Flax in, 15, 139
Iris cristata, 111; I. sibirica and its hybrids, 392; I. stylata varieties, 140; I. tectorum, 181
Ischarum eximium, 126
Ivy sports, 206
Ivy stem, a large, 174

J

JAMAICA Botanic Gardens, 222
Japanese Plums again, 52
Japanese tree strangler, the, 28
Jasminum nudiflorum, 94
Jubilee Year, retrospect of the, 8
Judging, the method of, at the Ghent Exhibition, 297, 316
Juglans regia var. rubra, 346; J. rubra, 139

K

KAKI, Loti, or Date Plums, the, 59
Kennedy and Hardenbergia, 229
Kensington Palace, 86
Kew Gardens, the earlier opening of, 233, 267, 280
Kew, horticultural training at, 56
Kew notes, 2, 49, 78, 94, 115, 140, 177, 226, 308
Kew Palace, 56; given to the public by the Queen, 43; grounds at, opened to the public use, 346
Kew, the rockery plants at, 325
King, Sir Geo., of Calcutta, 25, 168
Kitchen garden and other crops, thinning, 367
Kitchen garden, the, 6, 23, 39, 53, 68, 83, 98, 113, 124, 137, 151, 167, 182, 199, 214, 231, 246, 263, 278, 295, 310, 327, 342, 359, 376, 393
Kniphofia primularia, 49

L

LABELS for fruit trees, 60, 90
Lachenalia pendula var. Aureliana, 195
Lælia albida, 18; L. Amesiana, Crawshay's var., 59; L. anceps, 94; L. Protheroeana, 33; L. Schroderiana, 122; L. Waddoniensis, 117, 124
Lælia autumnalis varieties, 33
Lælio-Cattleya × Digbyano-Trianæi, 8; L.-C. × Lucy Ingram, 33; L.-C. "Pallas," var. inversa, 226; L.-C. Ridolfiana × var. Armainvilliersensis, 94; L.-C. × Sir W. Ingram, 226
La Mortola, plants in flower at, on New Year's Day, 34
Landscape gardening, lectures on, in Edinburgh, 198
Larix Lyali, 356
Lathyrus Sibthorpi, 286
Laudanum, 116, 130, 141

LAW NOTES:—Ashworth v. Wells (Orchid dispute, appeal case), 118; Claim for value of goods received, 284; Cookson v. Samson (misrepresentation of goods), 14; Ellis, Alfred,

Canton, Cardiff (Debtor), 349; Howcroft v. Laycock (Non-guarantee of seeds), 268, 398; Failure in business cases, 268, 287; Sheppard, H. J., florist (debtor), Bedford, 349; Smith and others (Agricultural Rates Act), 237; Smith v. Richmond (Rating of Glasshouses in Market Gardens), 168; Thomas Fox (Bankrupt), 398

Lawn-tennis court, how to make a, 120
Lawton's patent clip, 105
Leaf-miners, tar-water for, 201
Lee, a public park for, 250
Leguminous plants, propagation of, 66
Lepidium flexicaule, 284
Lettuce-forcing, 298
Libertia ixioides, 308
Lilies in Scotland, 390
Lilies, propagation of, 355
Lilium, auratum, 130; rubellum, 321
Lily of the Valley, the large-flowered, 149; rose-coloured, 348, 384
Linaria æquitriloba, 284
Linden, Jean, death of, 40; funeral of, 57; proposed monument to, 233
Liparis longipes, 274
Liverpool, new Palm-house for, 132
Livistona Woodfordi, 177
Lobelia, intertexta, 49; "Klothilde Pfützer," 234
London, congested spaces in, 363; open spaces in, 250, 362
Lonicera, fragrantissima, 221; × L. Standishi, 78
Luculia gratissima, and others, 88
Lycaste, fulvescens, 122; L. Schilleriana, 194

M

MACKENZIE & MONCUR's premises, fire at, 313
Magnolia Campbelli, 89; M. conspicua, 262; M. salicifolia, 374; M. stellata, 220, 374
Magnolias as forced plants, 139
Malformation in Scots Fir, 173
Manure - cartridge, artificial, M. Truffaut's, 264, 2-6, 317
Manure, fish as, 129
Manures, artificial, the, superior quality of British, 264; the abuse of, 184; the use of artificial, 274
Manuring of plants, ash analysis and the, 322; of various crops, suggestions for the, 346
Marantas, the cultivation of, 144
Marguerites, yellow-flowered, 330
Market Chrysanthemums, 20
Market-cultivation under glass, extension of, 268
Market-garden, where and how to start a, 20
Market-gardening, 52, 80, 103, 118, 134, 156, 194, 222, 292, 317, 381; at Loans, Ayrshire, 392
Masdevallia Pourbaxi, 178
Mattogrosso, Palms of, 234
Melon-Pear, the, 227
Melton Constable, Conifers at, 212
Methods of propagation, 213
Microbes in water, 317, 366, 382
Mildews of cereals, the, 232
Missouri Botanical Gardens, 297, 395
Moortebek, the Orchids at, 297
Morchella species, 318
Morello Cherry-trees, fan-trained, 314
Morisia hypogaea, 89, 104, 116
Mottisfont Abbey, trees at, 24, 60, 73
Muscari azureum, 140
Mushroom-growing extraordinary, 316
Mushrooms, "cluster," 381
Myrmecodia echinata, 5
Myrmecophilous plants, 5
Myrsiphyllum asparagoides, nitrogen in, 184

N

NARCISSI, seedling, 284
Narcissus attacked by mite, 237
Narcissus bicolor, Victoria, 140

Narcissus blooms from East Anglia, 380
Narcissus dubius, a yellow, 222; N. × Lady Margaret Boscawen, 275
Narcissus, relative merit of varieties of, 362
Nectarine Félix Faure, 221
Neill prize in horticulture, award of the, 313, 329
Nepenthes, Queensland, 26; N. ventricosa, 380
Nepeta glechoma variegata, 382
New Zealand, agricultural reports from, 222; recent botanical discoveries in, 321; some of the flora of, 260
Nicaragua, the Ferns of, 169
Nicotiana colossea variegata, 235
Nitrates in the soil, 210
Nitrogen, excessive, in Myrsiphyllum asparagoides, 184
Nova Scotia, Apples from, 202; a school of horticulture in, 260
Novelties of 1897, 1, 18, 34
Nurserymen's catalogues in continental languages, 58

NURSERY NOTES.—Balchin & Sons, 293; Beerlere, M. Van, 292; Carter & Co., Jas., 105; Charlesworth & Co., Heaton, Bradford, 128; Collins & Gabriel, Hampton, 294; Dereyghere Van Compernelle, Ed., Bruges, 276; Dobbie & Sons, Orpington, 373; Imaschoot, M. Odontoglossum bictonense, 94; O. crispum roseum, 306; O. c. Baroness Schroder, 164; O. c. var. Prince of Wales, 390; what becomes of the plants of, imported into England, 164; O. Halli, varieties of, 306; O. Insleayi, 18; O. Thibautianum, 226
Oncidium Batemanianum, 226; O. spilopterum, 121; O. unguiculatum, 78

Onion-bed, trampling on an, 330, 374
Onion trade, the lost, 213, 244, 285
Onions, imported, 237
Opuntia, papery-spined, 339
Orange, a trifacial, 58
Orchards, old, 17
Orchards in Victoria, 118
Orchid houses, the, 7, 22, 38, 55, 68, 82, 99, 112, 136, 150, 167, 182, 198, 214, 231, 246, 262, 278, 295, 310, 327, 343, 359, 376, 392
Orchid Notes and Gleanings, 15, 18, 33, 78, 94, 112, 148, 161, 194, 226, 273, 306, 338, 370, 389
Orchid, prices, 34; roots, fungus upon, 173, 206
Orchid sale, an, at Walton Grange, 313
Orchids at Barons' Halt, Twickenham, 306; at Cheam Park, 389; at Clare Lawn, East Sheen, 273; Glebelands, South Woodford, 180; Moortebek, the, 297; Oakwood, 127; Sunningdale Park, 370
Orchids, degenerate, do they? 49, 66, 67, 118; leaf-soils as a rooting medium for, 259; the loss of, from the Temple Show, 366, 344, 382; retarding flowers of, 57
Orchis Robertiana, 140
Ornithogalum lacteum, 73
Orphan Fund, the Royal Gardeners', 9, 25, 86, 126, 143, 157, 201, 249, 256, 330, 344; annual dinner, 256; annual meeting of the, 126
Ostrya carpinifolia, death of a fine specimen of, at Kew, 127
Oswald House, Edinburgh, 61
Oxalis crenata, 50

P

PÆONIAS, diseased, 398
Palisota Maclandi, 140
Palm-leaves, discoloured, 206
Palm, the Date, in India, 2
Palms, in the living-room, 77; of Mattogrosso, 234
Pancratiums, continuous flowering of, 91
Paris Exhibition, the, to be held in 1900, 394
Park, Widnes, the proposed, and its cost, 383
Parks, London, the cost of, 102
Parks and open spaces, London, 85
Passiflora alata, 104; P. Bonaparteana, 383; P. edulis, 52, 90, 102, 104, 117, 130, 204; P. Im Thurnii, 305
Pasteur's precautions when propagating plants, 280
Peach bloom, protecting, 286, 300, 316, 330
Pear, Beurré d'Amanlis, 311; Duchesse d'Angoulême, 46, 91; tree scale insects, 260; trees, Carmichael's, at Sandringham, 383; P. triomphe de Vienne, 246, 286, 311
Peas, decaying, 318; forced, for market sale, 366
Pelargonium Wilh. Langguth, 234; P. Meteor, 434
Pelargoniums, large-flowered, 181
Pennisetum Ruppelianum, 235
Perennials, hardy, for cutting, 194, 222
Phalænopsis × John Seden, 171; P. Schilleriana, 161
Phœnicophorum sechellarum, 246
Phytelephas macrocarpa, 177
Phytoptus on Hazel, 173; P. ribis, 173
Picea Omorika, a fossil species of, in Saxony, 169
Pine-apple culture, 220
Pine, Weymouth, disease of, 202
Pines, diseased, 119
Pinus, monograph of, 378
Pinus monticola, diseased, 244
Pitcher on leaf of Cabbage, 394
Pitcullen vineries, the, 71
Pittosporum bicolor, 115
Plane-tree, a grand, at Mottesfont Abbey, 24

THE Gardeners' Chronicle.

SATURDAY, JANUARY 1, 1898.

NOVELTIES OF 1897.

[T is interesting to turn over our notes of the new plants of the year that is past, as, in doing so, many facts become evident which were only unsuspected at the time from cursory observation. On the present occasion, the most striking fact gleaned from a study of the records of last year is, that the hybridist, who of late years has been plodding on with increasing confidence, may be said to have at last fairly over-reached the importer, for in every department of gardening, the majority of the novelties are home-made productions, and the outcome of the skill and perseverance of the gardener himself. It is to be hoped, however, that the present waste for garden hybrids will not render the efforts of the plant-collector and importer too unremunerative an occupation to pursue, the hybridist himself being dependent to a great degree on the importer. But a review of the introductions of the past year shows that the number of new species of plants are very few, and their introduction to our gardens is not of much consequence, and that they are chiefly noticeable by reason of the fine varieties among them which have flowered, and have in many instances doubtless saved the importer from suffering a loss on an importation.

ORCHIDS.

This applies more especially to the Orchids, among which the hybrids and the phenomenal varieties seem mainly to rivet attention; and, commercially considered, perhaps the rarer varieties of imported species, such as the more beautifully blotched *Odontoglossums*, *Cypripedium callosum* Sanderæ, and similar things, hold their own against the hybrids, high though the prices asked for the latter may sometimes be. Certain it is that whenever any rare old species, which has disappeared from gardens for many years, flowers, it receives as much attention, and is as interesting now as ever; as, for example, one of the greatest novelties to present-day cultivators which flowered during the year is a very old plant, viz., *Grammatophyllum speciosum*, with its gigantic 7-feet inflorescence of large yellow and brown flowers borne above the Palm-like foliage of the plant, which flowered in the gardens of Sir Trevor Lawrence, Bart., at Burford Lodge, in August last, and was awarded the Gold Medal and a First-class Certificate of the Royal Horticultural Society. In the same famous gardens many plants of as great merit have bloomed during the year, and among the numerous hybrid Orchids may be mentioned the fine *Vanda* × *Miss Joaquim* (teres ×

Hookeriana), some good *Cypripediums*, of which the most singular-looking one is *C. × hirsuto-Sallieri*, a large, glossy, pallid flower, distinct in appearance; the pretty *Brasso-Catt.-Lælia* × *Lindleyano-elegans* [*Phœbus*, what a name!]; and among the showy hybrid *Calanthes* raised at Burford, which graced the last meeting of the Royal Horticultural Society, some eight or nine new forms, of which *C. × sanguinaria*, with dark blood-red flowers; *C. × Burfordiensis*, rich carmine-crimson; and *C. × Veitchi splendens*, received awards. There also flowered in this garden the natural hybrid *Cattleya* × *undulata*, and the pure white *Stenoglottis longifolia alba* was shown. Many new plants, of botanical interest, have flowered at Burford during the year, and an attempt has been made to establish the singular *Trevoria Chloris*, named in honour of Sir Trevor Lawrence by Mr. F. C. Lehmann.

Baron Sir H. Schroder is getting more careful about risking his fine plants in public, and hence the difficulty in doing justice to the many novelties which have flowered at The Dell, examples of which were, however, seen at the great International Horticultural Exhibition at Hamburg, and at that held in the Temple Gardens. *Odontoglossums* always take the lead, and among those from Baron Schroder's collection certificated in 1897 were the magnificent *O. Wilckeanum* var. *Queen Empress*, which for size of flower, richness of the clear yellow and reddish-brown tints, excels all in its class; as does the fine, large, white *O. crispum magnificum*, also shown at the Temple in its own section. *O. præstans Dayanum*, also belonging to The Dell collection, is a charming white and cinnamon-brown flower; *Cœlogyne Dayana*, "The Dell var.," a great advance on the type form; and *Cattleya Loddigesii superba*, the finest example of its kind. Several cross-bred *Calanthes* and other Orchids have flowered at The Dell, but none surpasses the robust, handsome, and richly-coloured *Calanthe* × *Baron Schroder*.

Most of our important amateur collections have produced good things during the past year. From the Right Hon. Joseph Chamberlain's garden towards the latter part of the year there have been exhibited groups of good plants, either raised at home, or specially well-grown plants of the productions of others. Of the former, *Cattleya* × *Mrs. Endicott* (maxima × *Loddigesii*) has charming flowers, with the pretty purple veining seen in the lip of *C. maxima*; and of the latter, *Cattleya* × *Fabia*, and Mr. Cookson's *Lælio-Cattleya* × *Clive*, appeared in better form than they had ever been seen before.

The Hon. Walter Rothschild, who is great in "botanical" Orchids, has flowered several extraordinary *Bulbophyllums* and *Cirrhopetalums*, of which the wonderful *B. Ericsoni*, and the rare *B. megalanthum* may be noted. Also the new crimson *Mormodes badium*, and its clear yellow form *luteum*, and the pretty hybrid *Cypripedium* × *Enid* (*bellatulum* × *Spicerianum*).

R. Brooman-White, Esq., of Garelohead, a specialist in *Odontoglossums*, has received the Royal Horticultural Society's awards for three grandly spotted forms of *O. crispum*, viz., *O. c. heliotropium*, *O. c. Starlight*, so much admired at the last Temple Show, and *O. c. Sunlight*.

W. Thompson, Esq., of Stone, another admirer of the *Odontoglossums*, showed the beautiful *O. excellens*, Thompson's var.; *O. sceptrum aureum*, *O. crispum Annie*, and *O. Ruckerianum ocellatum*.

Fred Hardy, Esq., Ashton-on-Mersey, has to be credited with three very fine novelties; viz., *Cattleya Schilleriana*, Hardy's variety, the largest and best of the species; *Cattleya* × *Hardyana magnifica*, and the nearly white *Lælia pumila albens*.

Norman C. Cookson, Esq., from his abundant collection at Wylam, flowered the very singular looking *Lælio-Cattleya* × *Juno* (*C. Mossiæ* × *L. majalis*); *Cypripedium* × *Nansen* (*selligerum majus* × *Morganæ*); and *Phaius* × *Norman* (*Sanderianus* × *tuberculosis*), which excels the fine *P. × Cooksoni*, for a specimen plant of which Mr. Cookson was awarded a Silver Flora Medal at the Royal Horticultural Society last year.

De B. Crawshay, Esq., also a lover of *Odontoglossums*, has found favour with the very handsome *Odontoglossum crispum*, Mrs. De B. Crawshay, the large yellow purple-spotted *O. Andersonianum* *Bogaerdianum*, and the brilliantly tinted *Lælia-anceps* Mrs. De B. Crawshay.

Joseph Broome, Esq., of Llandudno, flowered *Cattleya Warscewiczii gigantea* fine in colour, and one that holds the record in size, viz., more than 11 inches across without unfair manipulation; and the handsome *Lælio-Cattleya* × *Broomeana*.

Elijah Ashworth, Esq., Wilmslow, received awards for the handsome *Lælia purpurata* Mrs. E. Ashworth, with broad rose-veined petals; the pearly-white *Cattleya Warscewiczii* Mrs. E. Ashworth, *Lælio-Cattleya* × *elegans* *Schroderiana*, and one of the first hybrids of *Cypripedium Chamberlainianum*, i.e., *C. × Haynald-Chamberlaini*.

Thos. Statter, Esq., showed among other good things *Cypripedium* × *Conco-bellatulum*; the handsome *C. × Rolfei*, and *Dendrobium Victoria Regina*, the blue *Dendrobe*.

G. W. Law-Schofield, Esq., in *Lælio-Cattleya* × *Tyntesfieldensis* staged at the Temple Show, had one of the best things of its class.

R. I. Measures, Esq., of Camberwell, one of the best Orchid growers in the neighbourhood of London, made a good show with the noble *Cypripedium* × *Chapmani magnificum*; the rose-pink veined *Lælia purpurata* Mrs. R. I. Measures; a violet-tipped *Rhyncostylis coelestis*, Cambridge Lodge variety; *Lælio-Cattleya* × *Andreana*, and *Miltonia* × *Peetersiana*.

Messrs. J. Veitch & Sons, Ltd., of Chelsea, again take a leading place for the fine quality and quantity of the plants they bring out. The number of their novelties that flowered during the year is so great that we are compelled to confine our remarks to those which have received the Royal Horticultural Society's awards. Of these specially acceptable are the number of autumn and winter-flowering *Cattleyas* and *Lælio-Cattleyas* which it has been Mr. Seden's special endeavour to produce. Thus, in the last four months of the year we find of Messrs. Veitch's plants that were certificated *Cattleya* × *Empress Frederick* var. *Leonata* (*Mossiæ* × *Dowiana*), a richly-coloured form of the original white-petalled variety; *Cattleya* × *Melpomene* (*superba* × *Warscewiczii*), a very showy hybrid, and, like that previously named, very fragrant; *C. × Melpomene* (*Mendeli* × *Forbesii*), and *C. × Olivia* (*intermedia* × *Trianaei*), both of moderate size, but having very distinct features; *Lælia* × *Olivia* (*xanthina* × *crispa*), a pretty flower with yellow sepals and petals; and several fine hybrids of *Lælia Perrini* have been shown which are very desirable by reason of the brightness of their flowers.

In February the handsome *Lælio-Cattleya* ×

Violetta (C. Gaskelliana × L. purpurata) flowered; and at different periods throughout the year Lælio-Cattleya × Digbyano-Trianæi, a close rival of L.-C. × Digbyano-Mossiae, and now in Sir Frederick Wigan's collection; L.-C. × Eudora superba (C. Mendeli × L. purpurata); L.-C. × Canhamiana albida (L. purpurata var. × C. Mossiae); Dendrobium × Ainsworthi intertextum, with primrose-yellow flowers, and purple disc to the lip; Spathoglottis × aureo-Veillardii, a perfect gem, with yellow flowers, charmingly marked with crimson; Phalænopsis × Hebe (Sanderiana × rosea), a fine companion to P. × intermedia Portei; Zygopetalum × Perrenondii superbum (intermedium × maxillare Gautieri), with vivid dark blue labellum; Cypripedium × Aeson giganteum (insigne × Druryi), C. × minos magnificum (Spicerianum × Arthurianum), and other good Cypripediums. Of special interest are the derivatives from hybrids of Epidendrum radicans raised by Messrs. Veitch, and which disclose unaccountable leaning towards that species, even when the seed-bearing plant has been of totally different growth and flower. Of these are Epilælia × radico-purpurata (L. purpurata × E. radicans), Epicattleya × matutina (C. Bowringiana × E. radicans), and Epidendrum × radico-vitellinum (vitellinum × radicans), all in some degree bearing resemblance to the finescarlet Epiphronitis × Veitchii.

(To be continued.)

CANNAS.

THE "ITALIAN" OR "ORCHID-FLOWERING" CANNAS.—No race of ornamental plants in recent years has awakened such a wide-spread interest at its introduction as the new and distinct type variously known as "Italian," "Orchid-flowering," or "giant-flowering," Cannas. The first variety announced was Italia, produced by Mr. Sprenger, of the firm of Dammann & Co., in Italy.* The variety Austria followed soon, however, and these have now been widely disseminated.

It was a remarkable coincidence that, at almost precisely the same time when these strange varieties were produced in Italy, Mr. Luther Burbank of California should have produced the variety Burbank very much like them, and by crossing the self-same parent forms! This peculiar race thus had two perfectly independent though simultaneous origins. The most striking and important characters of these new Cannas are these:—Blossoms of immense size, often from 5 to 6 inches in diameter (some of the advertisements say 7 inches and more, but this is improbable); flowers broadly opened; the petal-like staminodia very broad and full, giving a flower of magnificent form hitherto quite unapproached in Cannas; usually much-reflexed corolla lobes; peculiarly rich and clear colours; an unfortunate softness and fragility of the blossoms which, in our climate, seldom spares them for an entire day; large, broad, tough, Musa-like foliage; generally tall growth.

The breeding of this race is somewhat remarkable. The so-called "French dwarf" Cannas, which have become so popular in America in recent years, have been crossed and hybridised "in and in" until all the possibilities of the several parent species have become quite exhausted. In this condition an out cross with a species not before used was the evident part of wisdom. This out cross was made, both in Italy and California, upon the well-known variety Madame Crozy, and with the pollen of Canna flaccida, a species growing wild in the southern United States.

The soft, evanescent blossoms of Canna flaccida have been imparted to all the crosses thus far secured, but the race has been distinctly re-invigorated, and there have been developed striking and desirable characters till now unknown.

It would be of considerable theoretical and practical consequence could we, in this connection, know the full pedigree of Madame Crozy, the seed-bearing parent in these crosses. Unfortunately, this pedigree is only a matter of speculation, and seems likely to remain so. The general opinion among students in this branch of horticulture, seems to be that there are two groups of the "French dwarf" Cannas, the red-flowering ones, including Madame Crozy, having originated by crossing Canna Ehemanni with Canna Warszewiczii, while the yellow-flowering varieties are thought to have sprung from crosses of Canna Ehemanni with C. glauca.* If this view is taken of the origin of the "Orchid-flowering" Cannas, their complete pedigree will be approximately expressed in the diagram.

Antoine Crozy, the originator of Madame Crozy, and many leading varieties of that class, is, however, quoted in a recent interview as saying that he began by crossing Canna Warszewiczii and C. nepalensis, and that his yellow-spotted varieties were secured by subsequent crossing with C. aureo-picta, which is probably a horticultural form of C. indica, the old-fashioned "Indian shot."

This station has found opportunity in its greenhouse and on its ornamental grounds to grow several of the new "Orchid-flowering" varieties, and to compare them in flower and foliage with the best of the older standard varieties. Our opinion of them is, in general, that the varieties thus far introduced cannot become so widely useful as the "French dwarfs," and that they in no sense supersede the older varieties; that they are nevertheless a highly valuable addition to the list of ornamental plants; that they will be abundantly attractive to flower lovers, and useful to plant breeders as the basis for further crosses. We are especially pleased with the form of the flowers, which is peculiarly full, graceful and satisfactory, and with the colours, which have a velvety richness rarely equalled in nature or in art.

The following varieties have blossomed on our grounds, and the descriptions represent the plants as they develop here. We have several other varieties which have not yet blossomed:—

"Orchid Flowering" Cannas, Italia, Austria, Burbank, &c.	{	C. flaccida.	{	C. iridiflora.	
		Madame Crozy.		C. Ehemanni	C. Warszewiczii.
				C. Warszewiczii.	

Italia.—3 to 4 feet high, foliage broad, bright glaucous green; flowers very large, exceptionally well opened, with very broad and gracefully rounded staminodia (looking like petals); colour, a bright canary yellow, with dark cherry-red filling the centre, and running out in blotches upon the petal-like staminodia.

Austria.—Plant like Italia; flowers lemon-yellow, lighter than Italia, marked only with faint dots of pink in the throat. The flower does not expand so well as in Italia, and the form is not quite so good; but the colouring is very delicate and desirable.

Burbank.—Plant like Italia; flowers large, much like Italia in form, and like Austria in colouring; rich canary-yellow, with light red dots and markings in the throat.

America.—Foliage dark bronzy-red, with irregular dashes of dull green; flowering stem tall; flowers of the form and size of Italia; brilliant apricot-red, faintly spotted with darker salmon; the centre is canary-yellow, marked with the apricot-red of the body colour. The blossoms of this variety, in our opinion, exceed in richness of colouring any of the others which we have seen.

Professor Waugh, in Tenth Annual Report, Vermont Experiment Station.

* In this connection the following extract from a private letter from the eminent horticulturist, M. Henry L. de Villemorin will be of interest:—"It is the current belief in this country (France), and it seems confirmed by experiment, that the new breed of floriferous Cannas (i.e., the 'French dwarfs'), originated by the crossing of Canna Ehemanni with C. Warszewiczii and with C. glauca, the former producing the red flowers, and the latter specially yellow-flowered varieties. Both original crosses intercross readily, and in latter years I have had many crosses made every year, and raised and named several dozen new seedlings using the best varieties of my own and Crozy's raising, without introducing new blood into the breed."

KEW NOTES.

THE DATE PLUM.—This plant has fruited in the succulent-house at Kew annually for the last five years. The fruits are as large as a Valencia Orange and coloured bright orange-scarlet—a colour they assume about September. The fruits usually hang on the plant till about Christmas—long after the leaves have fallen, and are most palatable when blotted, like the Medlar. The plant is planted out in the gravelly border of the house among the Agaves, where it gets no shade in summer; it is heavily mulched annually with cow-dung. The branches are pruned in spring in the same manner as Pears. There is also a plant in fruit in the Mexican house.

CAMOENSIA MAXIMA.

The Kew plant of this African leguminous plant is again in flower, having set about a dozen heads a few weeks ago, several of which have withered, whilst the others have developed. There are six fine flowers open to-day (Christmas-Eve).

ARUNDINARIA HOOKERIANA.

Plants of the Himalayan Bamboo were sent to Kew last year by Dr. King, along with other species from the same region, and they are likely to prove suitable for the large new house. They have all grown freely and are now an attractive feature of that house, forming elegant tufts from 12 to 15 feet high. A. Hookeriana resembles A. falcata in habit and general characters. The Kew examples are 10 feet high, and consist of numerous barren leafy stems, and the newer flowering stems, which bear loosely-fasciated panicles of green flowers, with purple-brown anthers. According to Gamble, wild specimens are 15 to 20 ft. high, and the stems are about an inch in diameter, and striped green and yellow; at Kew they are of a bluish-green colour, as also are the leaves, which are 6 inches long, and five-eighths of an inch wide. The flowering of these plants will probably terminate their lives. One sent from Kew to Glasnevin is also in flower. It would be interesting to know if the plants in India are also now in flower. The species was described by Munro in 1868 from specimens collected in Sikkim by Sir Joseph Hooker, who states that the natives make cakes and beer from the seeds. W. W.

NEW NEPENTHES HOUSE, KEW.

Our illustration (fig. 1), affords our readers a good idea of the new structure recently erected in the Royal Gardens, Kew, for housing the extensive collection of Nepenthes. The building is connected with the group of glass-houses usually designated the T range, and is a low, span-roofed house, with moveable upper sashes. As the Nepenthes are suspended from iron rods attached to the roof, bench space is not required, and consequently it is not provided. The space on each side of the path is utilised for the cultivation of plants having similar requirements to the Nepenthes.

THE DATE PALM IN INDIA.

In the *Gardeners' Chronicle* of November 27, 1897, you notice the Annual Report of the Saharunpore Botanic Garden (India), and state that "Mr. Gollam does not report favourably on the Arabian Date Palm."

Having been—with the active help of the Government of India—the father of this experiment, will you allow me to say a few words on the "great misconception of the whole business" with which the reporters on the Date Palm in India deal.

Mr. Ridley, of Lucknow, writes to me in the same unfavourable strain regarding the Date-trees there. They seem to have run away with the idea that the object of the introduction largely of the cultivated Date Palm into the pains of India was to compete with the delicious sweetmeaty Dates that find their way into the London shops, and those of other great cities, from the Persian Gulf, Tunis, and other Date-producing countries, and to supply a delightful dry fruit for the palates of the higher classes of India.

Let me say, that this was not at all the object I had in view when I suggested the experiment to the Government of India. The object was to supply a

* The first announcement of these plants in the horticultural press seems to be that of *Revue Horticole* (Paris) 67, p. 31 (Jan. 16, 1895). The first general account of the race was published in *Revue Horticole* 67, p. 516 (Nov. 16, 1895). Additional notes and a chromo-lithograph appeared in the same journal for Feb. 16, 1896.

fruit during famine times, if the Date-tree were eventually largely disseminated throughout India.

I believe it impossible, excepting in Mooltan, Sindh, Rajputana, and other similar dry countries, for the Date-tree to ripen its fruit, as a sweetmeat, in the plains of India, where, during the ripening time, the rain is excessive. It rots, and there is an end of the sweetmeat!

But what of that? The Date is perfectly edible and nourishing some time before it ripens to the sweetmeaty stage. It has the crispness of an Apple, a nutty sweetness, and some astringency. This astringency is due to tannin, which, in ripening, seems to change into sugar, just as the acid of other fruits in ripening changes into sugar.

There is no fear whatever that the natives of India would not eat it in its unripe state, for I have seen the native children eat the nastiest wild fruits imaginable; and it was reported to me that the Dates of Pertabqueh (if I remember rightly) had no chance of ripening, for the children of the place ate them all up before they came to the mature stage. Moreover, there are certain kinds of Date-trees which never ripen their fruit to the sweetmeat stage. In the Persian Gulf the fruit of these is boiled, and thus the tannin is washed out of it, and afterwards it is dried in the sun. The Dates so treated are very nice, but they require good teeth to masticate them. If kept dry, they will last for a whole year or more. All those that are brought to India by Afghan merchants, under the name of *chohara*, are so treated, and I believe they are grown in some parts of Baluchistan.

In Spain the Date-tree is largely grown in the district of Elche, and this kind of Date is there pickled in vinegar.

In Mooltan, the conditions for ripening the Date are different from those of the other and more rainy parts of India. Some of the trees ripen their fruit in that district, and some do not, and the latter are fried in oil, and so keep for a long time.

I tried to ascertain the origin of the Mooltan Date plantations, but they told me that the tradition was that they grew after the invasion of Alexander the Great. The stones of the Dates that his soldiers had brought with them from the plains of Persia were scattered about, and so the Mooltan Date trees, from which the present local government derives a certain revenue, came into being!

I took infinite trouble to collect information about the Date plantations of the Persian Gulf, through the British resident there, and embodied the whole, with my own experiments, in a little book entitled, *The Future of the Date Tree in India*.

When I retired from the Indian Service, I collected information about the Egyptian Date-trees through the Director of Irrigation there; and also about the Date industry of Tunis and Algeria through the British Consul-General. The latter wrote to say that he had sent Tunisian Date seeds to the Government of India, enough to plant the whole of India! I dare say most of them were wasted, or eaten by goats after germination.

I also collected information about the Date-groves of Elche, in Spain, through the Secretary of the British Embassy in Madrid, and forwarded the whole to the government of India. Not improbably, it may be snugly kept in some pigeon-hole; but of this, I know nothing. The rule is, "If you want a thing done, do it yourself;" but it is obvious that, after returning from India, I could not plant the plains of India with Date trees. It is impossible for another person to get up the same enthusiasm—the *vis a tergo* for action—as the starter of the idea. Will anyone, however, undertake to declare that if, during the recent famine, there had been a hundred million Date trees in India, they would have been of no value whatever?

The wild Date-tree grows all over India, and ripens its small fruit; and it is my firm belief that where the wild Date grows, the cultivated tree, with some attention, will also grow, but somebody must plant it, and attend to it.

There was a notion formerly that Date trees grew in deserts. Nothing of the sort occurs. In the African desert it is only in oases, where there are

openings, that the tree can grow. In the Persian Gulf it is irrigated regularly, and so it is in Egypt. But the sweetmeat stage requires a dry atmosphere. It is also a mistake to suppose that a bunch of Dates ripens all over at once, like a bunch of Grapes. The dates ripen one at a time, and are collected and spread in the sun to dry.

I took some trouble to collect some Dates of the Lucknow trees which Mr. Ridley kindly sent me, and also of the Mooltan Dates, which the Deputy Commissioner there favoured me with. I sent them all, pickled in bottles, to the Director of the Royal Gardens, Kew, to show the size of the Lucknow and Mooltan cultivated Dates. They are to be found in the small economic museum (No 2) of the Royal Gardens, Kew. *E. Bonavia, M.D.*

THE BULB GARDEN.

FREESIAS.

It is, perhaps, some twelve or fourteen years since my attention was first called to these lovely winter-blooming bulbs. Passing along Market Street, Manchester, and gazing into the well-filled shop window of Messrs. Clibran & Son, a new and beautiful cluster of flowers filled me with such curiosity and admiration, that I immediately went in and enquired of the head shopman the name, class of plant, and any hints to its culture I could procure; of course, not enquiring for any secrets, nor expecting any. Freesias ever after came in the list of my winter-flowering subjects; and though, perhaps, at first my success was not altogether of the best, since then I think I may say I have succeeded as well, and perhaps better, than many who have endeavoured to grow them. I should just like to bear testimony to the admirable manner in which they are grown by Mr. A. Sturt, gr. to N. Cohen, Esq., Englefield Green, and the success that has followed when he exhibited a quantity at the Royal Horticultural Society's meeting last spring. From a photograph, I should say it was a very remarkable exhibit. Among a large collection of plants recently disposed of here, I had sixty, 5-inch pots, in three different stages. The first two dozen were pushing up their spikes of bloom, and by this time I should say are a mass of flowers. I had hoped to have a nice lot for Christmas, but others have them instead. I invariably potted the first batch about the first week in August, following other batches at about three weeks or a month. Five-inch pots were used, and a dozen or fourteen bulbs placed in each. The soil, amount of crocking, &c., was just similar to that we used for Roman Hyacinths, Tulips, &c. Whilst, however, these latter were stood outside, and a good layer of sand spread over them, the Freesias were placed in a cold frame, carefully watered, never allowed to get dry; if sunshine was too strong, a bit of shade was placed over the pots, air being given and other attention, as though they were growing plants. In a week or two the blades of leaves soon began to appear, and, keeping them in this position, the growth became strong, sturdy, standing up like Daffodils. By the middle of October the first batch were placed in a frame where more light and air could be given. Then, by the middle of November, they were placed on a shelf in the greenhouse, four stakes being placed round them, and a string of matting keeping the whole together. In the latter stages some manure and soot-water were given about twice a week, bringing increasing colour into the leaves and vigour in the spikes.

The spikes in almost every instance produced one or two laterals, which latter usually opened their flowers a little later than those on main stem. After flowering, the pots were placed again in cold pits, a little water at first being given, but gradually withheld, so that for three months at least the bulbs were in the pots, the soil of which was quite dry. During May the pots would be shaken out, the best bulbs placed in one box, lesser ones in another. They would then be kept in the dry till about August or September, when the same or similar processes would again be carried out.

By this means I always had a good lot of fine bulbs, stout and plump, for the principal batches; whilst the very small ones would be made up in pans and boxes very thickly, to grow on and increase for another season's culture.

The ease of their culture, the attractiveness of the plants, and sweet scent of the flowers, combine to make these one of the most acceptable things in a conservatory, or for house decoration. *W. Swan, late of Bystock, Exmouth.*

INDIA.

GARDENING UNDER DIFFICULTIES.

THE wild pigs still give a great deal of trouble. It is quite astonishing how they manage to get into the gardens. They have no fear for the watchman whatever, and just simply charge them, so that they have to bolt for their lives or take refuge upon a tree, when Mr. Pig helps himself with impunity to everything good—Sugar-cane, Indian Corn, and any other palatable food in season. I am sorry to say they attacked the grafted Mangoes this year. The spreading branches of these trees bear their delicious fruit near the ground, forming an easy prey to the pigs. To prevent further destruction, I had all the branches tied up so far as I could with safety, and was able to disappoint these nightly visitors. I am glad they cannot climb trees. I am sure if they could find any means of doing so they would. The pig is considered to be a rather stupid animal, but I am not of this opinion. If they would assist in ploughing up plots that required the plough, perhaps they might be of some assistance. They do not seem to understand that their services would be required in this way; their chief amusement is rooting up the flower-beds and knocking over flower-pots. During last March a lovely plot of Amaryllis was simply cut down through wanton mischief, cutting the flower-stems right through the middle.

There are other visitors. Monkeys, too, are very destructive, and visit the gardens frequently. They are also dangerous, and the watchmen are afraid to interfere with the large males. Their visits are during the day, but it is not so difficult to keep them away; once perched in a large tree it is difficult to dislodge them. A huge flight of locusts visited the gardens in June, and did much damage. The top of the Ingaulcis arbour was completely destroyed; for the time there was not a leaf left on the whole of this lovely avenue. I was glad their stay was short; the men with noisy instruments made a great noise, which caused the dreadful and destructive insect to take wing and fly off. The flying-foxes do much damage in the fruit garden, fruits of all kinds they devour greedily. When fruit is not to be had, they eagerly devour the foliage of the *Ficus religiosa*. They are extremely fond of all the *Ficus* fruits, especially *Ficus glomerata* and *Ficus indica*; and also fond of Guavas in all stages of ripeness. There is a colony of them outside the gardens in Sabrat Bilas. Fruit-growing in this part of India is very expensive, on account of the double watches night and day. Grapes, too, suffer when just getting ripe by black and red ants. I had ashes put in line all along either side of the stems to prevent the ants running up to them. I regret to say the Millingtonia avenue has been destroyed by the leaves being attacked by caterpillars, which have eaten off the leaves and are now busy in weaving webs, which I had to get brushed down from the under branches. The insects seem to keep floating about in mid air, which made it almost impossible to get along this drive in the morning. I am glad to notice the insects have not all their own way, flocks of insect-devouring birds are to be seen busily engaged in devouring these insects. When the insects have been quite satisfied they curl the leaf up round them somewhat like a Tea-leaf, and thus making it difficult for the birds to detect them; and I have no doubt the insects weave those tough webs to prevent the birds attacking them. The white ants devour superfluous outer dead, cork-like, bark of this tree, which I think does the tree good by its

removal. The ants also assist in removing the outer bark of *Vines*, which I think is the only assistance given by these pests in the garden. It is well known how destructive the ants are to all dead wood, such as labels, stakes, and posts of all kinds. In fact, they devour anything. Wooden garden-seats, and the roof of the potting-shed suffered badly, and the latter had to be re-roofed during the year. The ants work their way up through the masonry pillars, and devour everything on the roof with the exception of tiles. Seed-boxes cannot be left on the ground for one night without being attacked and eaten up in this way. They seem to have an instinct to find out dead wood, no matter where placed. I was astonished to find them discover and completely eat the wooden

tributed over certain parts of the host. In return for this the ants defend the plants against all sorts of enemies, rushing out of their hiding-places in an astonishing number as soon as any interference with their home makes itself noticeable. In another direction the ants contribute markedly towards the maintenance of the epiphytical species, inasmuch, the plentiful detritus carried up by them is made use of as nourishment by the host plant.

Such observations on mutualism or symbiotic appearances have shown that this kind of plant is by no means limited to groups of plants systematically closely related, but that we find them represented in various Natural Orders whose affinity is far apart from one another. This has caused not only the

illustration, is a native of Java; it is a smallish plant, perhaps never exceeding 1½ foot in height. The hypocotyl (caulicle) part of the young seedling swells up into a remarkably-sized tuber-like stem, which serves the plant in its natural state when exposed to dry and aerial atmospheric conditions, as a store of moisture; it is furnished with a considerable number of spines (modified roots), which extend along the stem up to its top. The flowers are fleshy, white, translucent, about half an inch long, and of short duration, lasting from four to six days. During this time they do not open, but keep closed till the flowers fall off the stem without being fructified, as observed on plants under cultivation.

The part inhabited by ants in this case is the fleshy, much-thickened portion, which stands originally below the cotyledons. Its curious development of the interior was formerly attributed to the action of ants, as was the production of the opening of the tuber (the passage connecting the interior with the outside). Under cultivation they have proved this not to be the case, both being developed spontaneously, wholly independently of the work and wounding of the ants.

The specimen illustrated (fig. 2) is a little over three years old, and grown from seeds, which is naturally wrapped up in a sticky integument, that enables it to adhere to any branch it may happen to fall upon, where germination soon takes place. The plant has been grown in a stove, in a very moist atmosphere, along with *Nepenthes*, in clean peat, and hung up close to the glass in a basket. The illustration will afford ample proof that those surroundings suit its requirements. *E. B. B., Berlin.* [There is a large collection of young plants at Kew, the seeds germinating with great facility; some are in the same stage of growth as represented, and others are larger. *ED.*]

FLORISTS' FLOWERS.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

IN a cold frame out-of-doors, cuttings will strike readily and continue sturdy. If we could be certain of the absence of frost so severe as to check the growth for weeks at a time, as is sometimes the case, I should more often be inclined to strike the cuttings in cold frames. Frost, I know, does not kill the cuttings of the *Chrysanthemum*; but whilst they are frozen they are not progressing, hence the advantage of a cool house whence frost is excluded.

I prefer to insert each cutting in a 60-sized pot, for the reason that the plants are easily transferred to larger pots without any check. When half-a-dozen cuttings are placed around the side of a flower-pot, the check given by disentangling the roots when potting-off is not good for them. The compost put into the cutting-pots may consist of equal parts loam, leaf-mould, and sharp silver-sand. Make it moderately firm, sprinkle a small quantity of silver-sand on the surface, which will be carried to the base of the cuttings with the dibber used, and this aids the formation of roots. Afford the cuttings a gentle watering to settle the soil about them, and stand them aside to let the foliage get dry, but not to flag. The lights must be kept close till the roots form, with the exception that they may be taken off an hour in the morning to permit of the dissipation of excess of moisture, and in the evening the glasses should be wiped dry. If these simple rules be carried out, the loss of cuttings from damping, so often experienced at this time of the year, will be prevented. Shading will not be required, unless the glasses stand in a very sunny spot, then a newspaper thrown over the lights for an hour or two in the middle of the day will suffice. In about a month the strong-growing varieties will be rooted, and a small amount of ventilation should be admitted by tilting the lights slightly at first, increasing the quantity until they can be safely removed. If potfuls of rooted cuttings can be removed to other hand-lights, the unrooted cuttings will be the better for being kept close. The soil must be kept sufficiently moist for the support of the cuttings or plants. *E. Molyneux.*

FIG. 2.—MYRMECODIA ECHINATA: AN ANT-HARBOURING PLANT.

labels I had placed on the timber trees, notwithstanding in many instances 8 feet from the ground. I conclude by stating that the white ants are one of the most destructive garden-pests in India. *T. H. Storey, Superintendent of the Gardens of H. H. Maharana Feroz Singhji, Oodeypore.*

MYRMECOPHILOUS PLANTS.

ONLY in the latter half of this century has special attention been paid to this interesting class of plants. They exhibit in certain parts very peculiar structural developments that are specially adapted for offering shelter and a home for whole colonies of living ants; also others that afford at the same time and to a certain degree food, in the shape of sugary excretions exuding from glands or similar minute bodies dis-

structure of the host to show various differentiations, but also the morphological position of the organs inhabited. *Myrmecodia* and *Hydnophytum*, shrubby plants of the *Rubiaceæ*, possess the greatest number of ant-plants, the much-widened portion of the plant contains numbers of hollows, a maze of passages for the inhabiting creatures. Besides these, we meet with them in the *Urticaceæ*, *Euphorbiaceæ*, *Myristicaceæ*, *Verbenaceæ*, *Leguminosæ*, and in the *Palmæ*.

Most striking, however, are the two genera of the *Rubiaceæ*, with which this characteristic development is most remarkable; consequently, they have been most subjected to the study and examination regarding the peculiar habit. They are of epiphytical habit, with opposite, leathery leaves, and producing small inconspicuous flowers.

Myrmecodia echinata, Jack., the subject of our

TREES AND SHRUBS.

ERICA MEDITERRANEA HYBRIDA.

In the collection of *Ericas* at Kew, there has flowered during the last two or three winters a singularly pretty heath bearing this name, under which it is catalogued by Messrs. Smith, of Darley Dale. It bears some resemblance to *E. carnea*, and if a hybrid (as the name would suggest), that species is no doubt one of the parents. Messrs. Smith may, perhaps, know its origin. Its great charm and value consists in its coming into bloom three or four weeks before Christmas, and thus considerably in advance of *E. carnea*. It is of neat, tufted habit, at present 15 inches or so high, and crowded with erect spikes, 3 to 5 inches long, of nodding, pitcher-shaped flowers of a pale clear rose. The blossoms are very like those of *E. carnea*, but the plant is a taller, stronger grower. There is nothing out-of-doors among hardy flowering shrubs at the present time so bright and pretty as this. It remains in good condition up to February or later.

FATSIA JAPONICA.

I have never seen this shrub flower so well outside as during the past autumn. The flowers are borne on large, branching panicles, 1 to 1½ foot long, at the ends of the branches, each division of the inflorescence ending in a spherical umbel of pure milk-white flowers. Against the deep lustrous green of the large, boldly-outlined, palmate leaves, the panicles are very effective, especially when they are as large and as freely produced as those just past. In the Bamboo garden at Kew there is a group of some half-dozen plants, which, owing to their exceptionally sheltered position, and possibly also to the mildness of the last two winters, are now really handsome evergreens. It is, of course, only in such places, or in especially favoured localities, that this *Araliad* can be grown outside with any satisfaction. But where the conditions are suitable, it ought certainly to be grown, not only for the beauty of the flowers and the season at which they appear, but also because the foliage is of a type distinct from all other hardy evergreens, and essentially tropical in character. *W. J. B.*

FORCING TOMATOS.

THE latest bulletin, No. 125, from the New York State Agricultural Experiment Station, is on the subject of forcing Tomatos in the greenhouse. While the bulletin treats of special problems in training and benching, the novice in greenhouse management will find many useful hints as the various steps in growing the crop are given incidentally but in detail to discussing the problems under investigation.

The question as to how Tomatos should be trained when forced as a winter crop in the greenhouse has long been a disputed one. In order to gain some light on the question, the different methods of training Tomatos have been under investigation at the station for the past two winters. The question of checking the growth of the plants in order to produce earlier fruit was also under investigation at the same time, and was carried on in part with the same plants that were included in the training experiments.

A comparatively large number of plants were included in these experiments and the results of each season's work agree, therefore the conclusions drawn are regarded as conclusive, at least for the variety of Tomato that was used in these tests.

In the training experiments plants grown to single stem were compared with plants trained to three stems. There was but little difference in the average size of the fruits of the two lots of plants, but the results show a gain for the single-stem plants in that they give a larger yield of early ripening fruit as well as a larger total yield.

In the benching experiments, plants planted in the soil on the benches in the ordinary manner were compared with plants that were not removed from the 2-inch pots, but were plunged in the soil on the benches. It is claimed by some that by plunging

the plants in the pots, the growth is checked, and this results in earlier fruitfulness. The results show that the ordinary method of planting is equally satisfactory, except that in some cases plants that were plunged in pots and trained to single-stems gave a little larger yield than similar plants not in pots.

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Apples and Pears.—Trees which from age and other causes make weak growth or fail to bear unrepresentable fruits, and whose leaves are small and pale in colour, are the first that call for attention from the gardener. Let the soil be removed down to the feeding-roots, carefully digging it out with steel forks, without destroying or injuring the larger roots. If the surface consists of turf, this must be put on one side, to be returned when the job is finished. If the trees are not cankered, it may not be necessary to lift any of the large roots; but after the smaller roots are found, a good dressing of chemical manure, rich in potash and phosphoric acid, should be mixed with the staple, and a small portion of new loam—only a small amount of nitrogen is necessary, as this is best applied later in the season, when growth is active, and above the manure named, put a half-inch layer of charred garden-refuse, lightly pointing it in with the fork, and then follow this with a 6-inch layer of half-rotted farmyard manure, and above this return the soil that has been thrown out. The addition of these new materials will raise a mound round the stem of the tree, but as the manure decays the soil will settle down to its former level. A mulch of strawy litter should be put on to keep out frost, and maintain moisture in the soil. If canker affects the trees, lifting the roots may effect some good, but the real cause of canker is now traced to a fungus which penetrates the wood through a wound in the bark, which may be got rid of by the use of the knife. Let an affected tree be gone over carefully, cutting out the cankered parts down to healthy tissue, and coating the wounds thus made with some thick paint made from clay and cow-dung, which will remain till the new bark grows and prevents the entrance of the fungus spores. All prunings should be burnt, or buried deeply. If a tree is to be lifted, the directions given above will hold good, excepting that all the roots as they are got out should be covered with damp litter till they are again laid in the earth. With full-grown pyramid or bushes which may not have been disturbed for years it is better to go only half-way round a tree one year, leaving the remaining half till the following year. When all the roots are free, make the bottom of the hole slightly convex; and if the subsoil be wet and unsuitable, put in rough stones, brickbats, &c., 6 inches deep as drainage; over these place a layer of thin turf, and then proceed to fill in, if possible, with loam that has been stacked for six months, and one-sixth part of charred refuse, as it furnishes potash and keeps the soil sweet. The roots must be replaced carefully and regularly as the work of filling-in goes on, and when the soil is returned, afford a mulch of strawy-litter or half-decayed leaves, and see that the tree is secured against the wind; those that are much exposed, and have been lifted, having three guy-wires fastened to them at two-thirds of their height, and the ends fastened to stout stumps, firmly fixed in the ground at a suitable distance from the stems. To prevent these wires doing injury to the bark, place a cushion of cloth, or a bit of india-rubber hose, round the stem, making it secure in its place. After replanting, thoroughly cleanse the stems and branches from moss, doing this in mild weather. Before beginning, spread a piece of canvas under the tree to catch the scrapings, which can be removed with an old table-knife on the small branches, and a hoe on the stems and big branches. The cleaning finished, take up the canvas and burn the scrapings forthwith, thus destroying the eggs and larvæ of injurious insects, as well as the moss and lichen. The stems may then be washed with a mixture of soft-soap at the rate of 6 oz. to one gallon of water, applying it warm, working it into all the crevices of the bark where American-blight harbours; and if 1 oz. of ordinary brown carbolic acid be added to the mixture, which must be kept stirred up during its use, and applied again at intervals during the summer, this will keep the American-blight in check, and the wounds made by the aphids will heal up. The

American-blight insect often hibernates at roots of the trees, just under the surface of the ground, and search should be made for it in that direction also.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Winter-flowering Begonias.—For decorative work at this time of the year, this beautiful class of fibrous-rooted Begonias is extremely useful, and late batches of *B. Gloire de Lorraine* will continue in flower for a length of time, being followed by *B. Gloire de Sceaux*, *B. socotrana*, and *B. manicata*. Water must be carefully afforded, in order to maintain the plants in health, and weak manure-water twice a week with beneficial effects. A medium sort of temperature, and a position where they receive all the light possible, yet slightly shading them from bright sunshine, suit them well. Plants of *B. Gloire de Lorraine* which have flowered should be cut down to afford when they break shoots, suitable for cuttings.

Sericographis Ghiesbreghtiana.—The most forward plants, being in flower, should be planted in a cooler house for a few days, in order to prepare them for employment in the house or the conservatory. They associate well with *Begonia manicata* and Palms; and they make light and elegant display for small groups and *jardinières*. The later-blooming plants, and those infested with mealy-bug, should be thoroughly cleaned, using methylated spirits of wine applied with a soft small brush, which is certain death to them.

Euphorbia pulcherrima.—Plants from which the bracts have been removed may be gradually hardened off, and then kept quite dry; but those plants which still retain their heads of bracts in good condition should be kept in a coolish house, water being sparingly afforded them, and they will then continue in good condition for some time longer. If the heads are removed after the plants have been hardened off, the former will keep fresh for a considerable length of time.

Chrysanthemums.—The cuttings inserted towards the end of the month of November and during December should be closely inspected, making good any losses. The present is a good time to put in cuttings for forming bushes, which, if left to a later period, when there is a considerable pressure of work, do not always receive the necessary attention. The soil for filling the cutting-pots should be of a rather light character—fresh loam with a fair amount of leaf-mould and sand answering very well. The pots used should be quite clean, otherwise in turning out the ball it is apt to stick, and this is damaging to the roots, and checks growth. For striking cuttings to form bushes, small shallow boxes answer admirably. Before putting in any cuttings, see that they are free from green-fly; dipping them in some liquid insecticide. Plunge the cutting-pots in coal-ashes or cocoa-nut-fibre refuse; and, if a light or two, in a cool pit where heat can be applied when required can be utilised, so much the better, as the cuttings can then be brought close to the glass, which ensures a short sturdy growth when the cuttings commence to grow. If the striking of cuttings is carried out in tall glass-houses, boxes deep enough to allow sheets of glass being placed over the cuttings when plunged therein should be used. The shading of the cuttings must be closely attended to when the sun is bright in order to prevent flagging of the leaves. Afford the cuttings one good application of water, and dispense with fire-heat as much as possible, only making use of it to prevent the temperature falling below 45°, or to disperse excessive moisture.

Richardias.—Those plants from which the spathes have been cut should be rested for a short time in a cool green house; but those which are growing freely and showing spathes require liberal treatment. If aphids be found on the plants, fumigate or vapourise them on two successive evenings, afterwards syringing the plants thoroughly.

THE KITCHEN GARDEN.

By J. W. MCHATTIE, Gardener, Strathfieldsaye, Hants.

Mushroom-house.—Let fresh beds be made up as often as may be required to maintain the supply, and keep the temperature at or below 60°, and the air moist.

Cauliflower and Lettuce plants in cold frames will need plenty of air during mild weather, to keep them sturdy.

French Beans.—Sow seed frequently, using 8-inch pots, half-filled with rich light loam, pressed mode-

rately firm, eight to ten seeds being placed in a pot, with an inch of soil lightly put above them, and place the pots in a Cucumber-house or Pine-stove. The varieties that are good forcers are Ne Plus Ultra, Syon House, and Osborne's Forcing, and bear in mind the proverb "The more hurry the less speed." Keep the temperature equable at from 60° to 70° by night, to 70° to 75° by day, or a little higher if the sun shines.

General Remarks.—If weather permits, let all spare ground be dug or trenched, and get a plot of ground in readiness for sowing early Peas and Broad Beans. The soil for these early crops should be rich but light, and well drained, so that water does not accumulate in it and rot the seeds before germination has taken place. During hard frost, prepare to go on with trenching and digging, by turning the manure-heaps and getting the decayed portion set aside for wheeling on to the vacant plots in readiness for being spread when wanted. Stable-litter and tree-leaves should be collected for the making of hot-beds for the forcing of early vegetables; and turn over, prepare, and lay up the various composts to be used in the frames. Protect Parsley by placing cold frames over it, and cover these with mats during severe frost, but affording plenty of air during mild weather. Dry fern worked between the rows is a great protection during hard frost when frames cannot be afforded. Lift, pot, or box-up roots of Mint or Tarragon, and place the same in gentle heat; also roots of Seakale, Asparagus, and Rhubarb may be lifted in mild weather and placed in a cool-house which frost cannot enter, in readiness for forcing in batches, always aiming at keeping up a constant supply of these much-prized vegetables.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

General Remarks.—Although our knowledge of Orchid cultivation has made considerable progress during the past few years, there yet remains a great deal to be learned, and every grower should be on the alert to pick up useful hints that are likely to be of use in the cultivation of this interesting order of plants. I will endeavour to give such methods as I have found to be suited to their requirements under cultivation. The proper and safe road to success is by close observation. Much can be learned by visiting the collections of other persons, ascertaining, if possible, the mode of culture employed, and noting the positions occupied by the healthiest plants. The various structures in which Orchids are cultivated are the East Indian or hottest house, the intermediate and cool or the Odontoglossum-house, in which, providing the ordinary requirements of the plants are attended to, almost every Orchid from tropical countries can be grown; but where large numbers of any particular species have to be grown, it is advisable to provide a separate house for them. For instance, besides those mentioned, there are at Burford a Cattleya-house, a Mexican-house, and a Masdevallia-house. The Cattleya-house is kept at an intermediate temperature, the Mexican-house containing such plants as *Lælia anceps*, *L. albidula*, *L. autumnalis*, *L. Gouldiana*, *Odontoglossum citrosum*, *Luisias*, *Cattleya maxima*, *Epidendrum atropurpureum*, *E. nemorale*, *Broughtonia sanguinea*, &c., is without sun-heat a trifle under the temperature of the intermediate-house; and the Masdevallia-house is a degree or two above that of the coolest division. Such a structure as the last-named is a very convenient one in which to grow *Colax jugosus*, *Maxillarias*, *Lycastes*, *Odontoglossum pulchellum*, *O. Uro-Skinneri*, *Miltonia Warscewiczii*, *Dendrobium Jamesianum*, *D. infundibulum*, *D. Wattianum*, *D. longicornu*, *D. cœmulum*, *Anguloas*, *Cypripedium insigne*, *Epidendrum vitellinum*, *Pleurothallis*, *Restrepias*, *Zygopetalum maxillare*, various *Oncidiums*, &c. Where no such abundant accommodation exists, the warmer part of the cool-house, or the coolest part of the intermediate-house, should be utilised, as the case may need. The present time being about the middle of the resting and slow-growing period, which extends from November to February, the following night temperatures should, when maintained by fire-heat, range as follows:—East Indian-house, 60° to 65°; Cattleya or intermediate, 55° to 60°; Mexican, about 55°; *Odontoglossum*-house, 50°; a few degrees less is beneficial during exceptionally cold nights when the air in the houses, owing to the unusual amount of fire-heat used, is comparatively speaking dry. The day temperature should be several degrees above those indicated as maintained by fire-heat alone, but a rise of a few degrees by sun-heat is

always beneficial, and should be permitted. On cold, bright mornings the temperatures of each division should be raised by small sharp fires, so that by the time the sun makes its appearance the fires will be so low as to send forth but little heat. At such times, if the furnaces are kept full of fuel, the pipes become so hot as to cause the atmosphere to become more than ordinarily dry, and injury to the plants resulting from a continuance of this state of things would soon show itself. It is very essential that Orchid-houses should be well ventilated at the top and bottom, so that whenever the external air is calm and mild, it may be admitted, as all Orchids delight in fresh air when afforded with care.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Grape Vines.—About the New Year many gardeners commence forcing Vines, either in the first or succession vinery. The Vines for starting at this time should have been pruned and dressed, and the vinery otherwise prepared at the least six weeks previously. Examine now the soil of the border in which the Vines are growing, and if it is found to be only slightly moist, afford a good application of tepid water; and if the Vine-roots are in an outside border, place a covering of Oak-leaves, sufficient in bulk to generate a slight degree of warmth, which will keep out the frost, and maintain warmth in the soil. The temperature, when commencing to force Vines, should be about 50° at night, 55° by day with fire-heat, with a rise of 10° to 15° by sun-heat. Put on air by degrees as the temperature rises, in accordance with the amount of heat in the hot-water pipes, and the condition of the atmosphere outside. The syringing of the rods and damping of the floors and walls of the vinery may be done once if the day be damp, and on a fine day three times is not too many. Those Vines that were started in November, if conditions have been favourable, will have now started into growth; and as soon as it can be seen which shoots are showing for fruit, those not required may be removed, always bearing in mind to leave plenty of bunches for a crop, and shoots to cover the trellis without crowding them together. Before the young shoots reach the glass tie them downwards with broad strips of bast a little way at a time; the shoots on early Vines are not, however, so liable to be broken in tying them down as are those of late Vines, but still it is safer to deal tenderly with them.

Late Vines.—If the fruit is still on the Vines, it should now be removed with sufficient wood attached as will go into bottles filled with water, in which they will go into the Grape-room. Of course, a shoot should not be cut so severely as to take away the bud required to produce the bunch next season, two buds at least being left in front of that one. All the late Vines should now be pruned, cutting the laterals to the most prominent bud that is near to the rod, the length of the leading shoot being according to requirements, but 3 to 4 feet is a sufficient length to retain in one year, if there be space for so much. In the case of young Vines, if the leader be left longer, it does not always break along its entire length. By pruning early, time is given for the wounds to dry before the sap begins to rise, and bleeding is then not likely to occur. Remove as many of the long snags and spurs and all the loose bark that comes away with a rub, and afford a good washing with soft-soap and water, at the rate of 8 oz. of soap to the gallon; and dress them with a mixture of 8 oz. of soft-soap, $\frac{1}{4}$ pint of XL composition, and $\frac{1}{2}$ lb. of flowers-of-sulphur to 1 gallon of water, made of the consistency of paint with clay and a small quantity of cow-dung. This should be well worked into all crannies, and especially round the spurs, with a painter's brush. Having done this, thoroughly wash the glass and the wood-work, and whitewash the walls of the vinery, adding $\frac{1}{2}$ pint of petroleum to every 2 gallons of whitewash. The surface soil of the border should be pricked off carefully down to the roots and carried away, replacing it with eight parts good loam, lime rubbish one part, charred soil one part, with an 8-inch potful of bone-meal to each wheel-barrowful of soil. From this time until the Vines are started, the vinery should be kept cool. In frosty weather no harm will occur to the Vines if the temperature in the vinery sinks 4° to 6° below freezing-point; but at such times circulation should be slightly maintained in the heating apparatus.

The Grape-room should be dry, and provided with a small amount of hot-water piping, a ventilator being fixed at the top. There should be racks for holding the bottles at an angle of about 45°, so that the

bunches may hang clear of them, and the bottles should be almost filled with rain-water, with a little bit of charcoal in each. About 50° is a suitable temperature for this room, and it is advisable to keep a slight degree of warmth in the pipes, and to open the ventilators on every fine day, from about 9 A.M. till 4 P.M.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Changes in Flower Gardening.—That inevitable destiny of mundane things change has within the last few years greatly altered the style and aspect of the flower garden. And still there is room for further alterations and improvement. The laying out and beautifying of a flower garden does not only consist of planting masses of bedding plants grouped together in geometrical designs, but it includes, or should so do, the use of ornamental trees and evergreens and deciduous shrubs planted in a manner both as regards position and variety, that will give added charm to the whole, and being so arranged and designed that the beauty of the other portions of the garden is enhanced, and at the same time the latter blends harmoniously and gradually with the surrounding landscape. If it be the intention of the owner or his gardener to carry out the planting of trees and shrubs this year, no time should be lost in pushing on with the needful preparations, weather permitting, with expedition. In large beds and shrubberies nothing looks better, especially in the former, than standard trees of *Prunus Pissardi*, planted at intervals in number according to the size of the bed, the remaining space being filled with dwarf plants of *Acer Negundo* variegata. The effect of this style of planting on a large scale, if not overdone or to the exclusion of other shrubs, especially when the bed is on an expansive lawn, is very fine, the dark purple leaves of the *Prunus* standing out in bold relief above the green and white variegation of the *Acer*. Yellow-leaved Elder and Privet are likewise telling plants when placed in groups towards the front of a shrubbery. The former, when planted in this manner, to be pruned in the spring months, for the plant grows with great rapidity, and its foliage is of a much brighter hue if pruned than when allowed to grow at will.

Rosa rugosa.—This species, and its variety *alba*, lend themselves to this style of planting with good effect. They flower continuously throughout the summer; and in autumn the bushes are covered with the scarlet-coloured haws, while the leaves change to a beautiful golden-yellow tint. There are many other beautiful deciduous and evergreen shrubs too numerous to be mentioned here, which if planted with discretion as to selection and variety will add greatly to the charm of a garden. In planting trees and shrubs it is important to take care that the holes are of sufficient size to enable the roots to be extended to their full length before filling-in. When the planting of choice shrubs is performed, unless the land has been trenched and manured in the autumn, it is good practice to use some prepared soil of a fairly rich nature, mixing it with the staple, and covering the roots with a layer of it, at the least, 4 inches thick. American plants should be planted either in peat that has been in stack for one year, or in light fibrous loam. With these plants no stronger manure should be employed than leaf-mould, and with peat even this is not needed. When a shrub has had its roots covered partially with soil, water may be applied heavily to wash the particles of soil in among the roots; the rest of the soil being then returned to the hole and made firm. A mulch may be used over the roots, and a stake placed so as to secure the plant firmly.

The Rose Garden.—The planting of Roses should not be delayed if the weather keeps open, planting them firmly, and mulching with strawy manure. The standards should be staked forthwith, fastening the stems with loose ties, to allow of the roots sinking. Tea Roses may be covered lightly with bracken. Attend to the nailing-in of the long shoots of climbing Roses, and put the walks and grass verges in good order for the season.

General Work.—Let the fallen leaves be collected from the fronts of shrubberies, where they are likely to blow out and litter the garden. Afford the lawn and the walks a rolling as time and weather permit. Examine Dahlia tubers, removing any that are unsound; also the tubers of Begonias. Pay particular attention to the bedding Pelargoniums, affording them but little water, but as much air as possible in mild weather; keep the glass clean, and remove decayed leaves frequently.

APPOINTMENTS FOR THE ENSUING WEEK.

SALES.

WEDNESDAY, JAN. 5	Japanese Lilies, Tuberoses, Continental Plants, Roses, Palm Seeds, &c., at Protheroe & Morris' Rooms. Rose and Fruit-trees, Shrubs, Border-plants, Bulbs, &c., at Stevens' Rooms.
THURSDAY, JAN. 6	Continental Plants, Dutch Bulbs, Roses, Herbaceous Plants, &c., at Protheroe & Morris' Rooms. Border-plants, at Stevens' Rooms.
FRIDAY, JAN. 7	Important Sale of <i>Odontoglossum crispum</i> and <i>Cattleya aurea</i> , by order of Mr. T. Rochford, at Protheroe and Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—36° 4'.

ACTUAL TEMPERATURES:—

LONDON.—December 29 (6 P.M.): Max., 55°; Min., 46°.
PROVINCES.—December 29 (6 P.M.): Max., 54°, south-west Ireland; Min., 43°, Orkney.
Weather mild, wet, and stormy.

Retrospect: THE year is not too far advanced yet to preclude us from alluding, The Jubilee Year. by way of retrospect, to its predecessor. One word, and one word only, might serve to characterise the year that has passed—"Jubilee." Our thoughts, our work, our engagements, our flower-shows, were all largely affected by this most memorable occasion. For our own parts, while providing for the present body of workers, we considered also the work of our predecessors, and the claims of the gardeners of the future, and thus it was that our columns were largely filled, even to the end, with articles relating to the progress of horticulture in the QUEEN'S reign. For statistical and historical purposes, this retrospect, ranging over almost every department of horticulture, can scarcely fail to be of use, whilst the student of evolution and progressive change will find a wealth of material placed at his disposal. Those concerned in the history and development of horticulture and of cultivated plants, would do well to preserve the two volumes containing, as we believe, a fuller and more varied retrospect than has ever before been got together.

In addition to the general articles, we published three special commemoration numbers one containing views in Buckingham Palace Gardens by the special permission of HER MAJESTY. It is thirty years since any similar views were taken, and even then they were not made public. Londoners must have been astonished at the beauty of the grounds in the rear of the palace, and in the heart of the great city with its ceaseless roar.

Our list of the trees planted by HER MAJESTY in various localities, with the dates of planting and other interesting circumstances, is we believe unique. In its construction we were assisted by Mr. MALCOLM DUNN, and other good friends.

Of exhibitions, that at Hamburgh, or rather that series of exhibitions held during the year on the banks of the Elbe, takes foremost rank, and was, all things considered, the finest and most representative exhibition ever held.

Our own exhibitions are constantly increasing in number, particularly those devoted to the Chrysanthemum. The great shows at the Temple and at the Crystal Palace, held under the auspices of the Royal Horticultural Society, were admirable.

Among the meetings we must not fail to allude to the very agreeable gathering of all the committees at Chiswick. This meeting was so much appreciated that we hope it may be at least of annual recurrence. The progress and development of Chiswick are matters of the

very foremost importance to the Society and to horticulture generally.

The Society has also attempted, and successfully attempted, a very delicate and difficult task in the conferment of Medals of Honour by the express consent of HER MAJESTY, on sixty recipients. The matter is too recent to need further reference now, but as the weeks pass we have increasing evidence that the allotment of the Victoria Medals of Honour gives general if not universal satisfaction.

Manchester, Shrewsbury, Edinburgh, Belfast have all been in the front rank, and York would have been so also, save for the disastrous cyclone which ruined its prospects, and entailed a loss to the Society of £600.

The crops were fairly good, except in the case of fruit, Apples and Plums being especially deficient.

Horticultural literature has been enriched by some remarkable books, such as the Duke of BEDFORD'S *History of a Great Agricultural Estate*, and the first annual report of his Grace's fruit farm, near Woburn. The completion of the *Flora of British India* has been recently alluded to, as well as the very welcome re-appearance of the *Flora Capensis*, and of the *Flora of Tropical Africa*. All these will be of great value to horticulturists. Dr. LOWE'S book on the *Yew Trees of Britain* is one that will not lose its interest as time goes on. The *Life of Babington* is of interest as a record of many things relating to British botany and botanical affairs generally. Prof. GOFF has published an excellent little, elementary treatise on *Vegetable Physiology*, as applied to gardening; and the reference to book notices in our indexes show that much has been done in the domain of literature.

Had we to speak of pure botany only, we should allude to the remarkable discovery by two Japanese botanists of spermatozoids in the pollen-cells of Ginkgo and Cycas as the most epoch-making botanical discovery for many years. The bridge between the Ferns and the Conifers and Cycads, formerly separated by a great gap, is thus established. At present, it has no bearing on practical horticulture, but we never can tell how soon, or to what extent the discoveries of science may be pressed into the service of practical work.

The old notion of the integrity of each plant-cell—an article of faith successive generations believed in—has been upset by the discoveries of Mr. W. GARDINER at Cambridge. The continuity of protoplasm—that is, the passage of minute threads of protoplasm from cell to cell—was discovered a few years since, but it has received additional confirmation this year. The result is, we must look on the plant as a connected whole, and not as a series of detached fragments, with little or no direct intercommunication. This view of plant-life, it is evident, has a very important bearing on practical horticulture.

The death-roll is heavy, and our losses severe. We have lost ROBERT HOGG, TREVOR CLARKE, and JAMES BATEMAN, a trio never to be replaced. In addition, we may mention the names of ALFRED SUTTON, one of the founders of the house of SUTTON; Mr. CHARLES SHARPE of Sleaford, who did so much to secure the passing of the Seed Adulteration Bill; BAILLIE of Chester, JAMES WEBBER of Covent Garden, HEAD of the Crystal Palace, OWEN of Maidenhead, COCKER of Aberdeen; STILES, the sympathetic and power-yielding Acting-Editor of *Garden and Forest*; LODEMANN,

the young enthusiast, from whom so much might have been expected; POCHIN, of rosarian fame; PFAU, and PARISH, the well-known Orchid collectors; and many others whom we need not name, but who will be held in pleasant reverent memory for many a year to come. Perhaps in this connection we may mention the death of the Duchess of TECK as of one who took great interest in flowers and in the work of the horticulturist. Her genial presence at our shows will be much missed.

The gardening charities have been fairly well supported during the year, and the gardening community ought to feel under great obligations to the committees and others who work so disinterestedly on their behalf. The best way of showing such obligations is to send cheques to the secretaries, and so do something to alter that distressing statement annually made, that the number of worthy and approved candidates is always in excess of the number that can be elected. The beginning of the year is a time to frame good resolutions, and, better still, to put them into practice. We append the address of the Secretary of the Gardeners' Royal Benevolent Institution—G. J. INGRAM, Esq., 50, Parliament Street; and A. F. BARRON, Esq., Chiswick, the Secretary of the Royal Gardeners' Orphan Fund—the latter, it will be remembered, founded in the first Jubilee Year, and growing favourably in the last celebration.

LÆLIO - CATTLEYA × DIGBYANO - TRIANÆI (CATTLEYA TRIANÆI ♀, LÆLIA DIGBYANA ♂).—Our illustration (p. 9) represents the beautiful Lælio-Cattleya × Digbyano-Trianæi, which the raisers, Messrs. JAS. VEITCH & SONS, of Chelsea, exhibited at the Royal Horticultural Society on April 13, 1897, when it received a First-class Certificate. It is one of the finest novelties of the past year, and it passed into the collection of Sir FREDERICK WIGAN, Clare Lawn, East Sheen, Richmond (gr., Mr. W. H. Young). Its beautiful flowers are white, tinted with various shades of bright rose-colour, and like its handsome ally, L.C. × Digbyano-Mossiae, it is very fragrant. While we are strongly of opinion that the pedigree should be recorded in all these cases, we do not think it should form part of the name, a short arbitrary designation being far more convenient.

THE ROYAL SOCIETY.—In the current number of the "Proceedings of the Royal Society" is contained a paper by Dr. BROWN. The experiments were undertaken for the purpose of determining whether any change whatever goes on under ordinary conditions in resting seeds. There were three cases to consider: respiratory changes, intra-molecular respiration, and changes not attended with the evolution of gas. With reference to the first, it had been shown long ago that no gas was given off when the seed was kept for a year *in vacuo*. Their vitality was retained also when the seeds were kept for nine months in the vapour of ether and in hydrogen. The existence of intra-molecular respiration was disproved by keeping the seeds for several months in Geissler-tubes, the absence of nitrogen and carbon dioxide being shown by the spectra. To attack the third question the authors had subjected the seeds to extreme low temperatures, with the idea that if any activity existed in the seed its vitality under these conditions would be destroyed. About eight or ten species, taken from five or six families, had been treated. After being kept for 110 consecutive hours at a temperature of about -190°, the seeds were carefully thawed and set to germinate by the side of untouched seeds of the same samples for comparison. In all cases the frozen seeds grew as well as the others. Similar results were obtained by M. C. DE CANDOLLE.

ROYAL GARDENERS' ORPHAN FUND.—A meeting of the Executive Committee was held at the Horticultural Club on the 22nd ult., Mr. WILLIAM MARSHALL in the chair, when the following special

donations were announced:—Altrincham Gardeners' Mutual Improvement Society, proceeds of concert, £18 5s.; Rugby Chrysanthemum Society, per Mr. V. Bryant, £7; Mr. C. Ross, the Gardens, Welford Park, Newbury, £6 11s.; Mr. J. H. Vallance, Bristol Chrysanthemum Show, £5 5s.; Penshurst Gardeners' Association, £3 5s.; Mr. H. Herbst, Stanmore, Rich-

7s. 6d.; Mr. J. Lyne, Chislehurst, 7s.; Mr. F. Dodds, Herringswell, Mildenhall, box, 9s.; Ware and District Gardeners' Society, 6s.; Young Men at Gordon Castle, Fochabers, per Mr. C. Webster, 5s.; Mr. A. H. Palmer, Tiverton, 5s. The Secretary announced that the sum of £422 7s. 4d. had been received as the amount of the J. W. Thompson bequest. Appli-

reported, in reference to the defective lighting at the November Show at the Royal Aquarium, that it was caused by a derangement of the lighting apparatus, and that the directors had done their best to supply the failure on the part of the contractor. That as the repairs necessary before the western gallery could be lighted by electricity would occupy

FIG. 3.—HYBRID CATTLEYA = C. TRIANAËI AND C. DIGBYANA. (SEE P. 8.)

mond, box, £3 1s.; Chislehurst Gardeners' Mutual Improvement Society, per Mr. H. Yoell, £2 17s. 9d.; Tonbridge Gardeners' Association, per Mr. G. Fennell, £2 10s.; Mr. J. Miles, Dudley Villas, Southampton, £2 3s. 6d.; Mrs. M. Buller, per Mr. G. Bolas, Wirksworth, £2; Mr. J. Rollend, Newton Abbot, box, 10s.; Mr. T. Wilkins, Inwood Gardens, Henstridge, 10s.; Mr. G. Mason, Rosebank, Malvern,

cations were received in the interest of eighteen children candidates for election on the Fund at the annual general meeting on February 18 next.

NATIONAL CHRYSANTHEMUM SOCIETY.—A meeting of the general committee took place at Anderton's Hotel, Fleet Street, on Monday, the 20th ult., Mr. T. W. SANDERS presiding. The secretary

some days, the directors had added new and powerful carbon burners, and the light at the December show had been greatly improved in consequence. It was agreed that two of the dates published as meetings of the Floral Committee in 1898, viz., November 28 and December 12, should be withdrawn from the list. The Secretary brought up the report of the Schedule Revision Sub-committee, in which

it was proposed to create a new class at the November Show—for twelve vases of specimen Japanese Chrysanthemums distinct, five blooms of each, £50 at least to be given in prizes. It was reported that the president, Sir EDWIN SAUNDERS, had offered to give as the 1st prize the sum of £15. The secretary also reported that in commemoration of the fact of the National Chrysanthemum Society having held their exhibitions at the Royal Aquarium for the space of twenty-one years, the directors had voted the sum of £30 as special prizes in the class for twenty-four Japanese, £25 of that sum being divided into money prizes; the Gold Medal of the society, suitably engraved, being added as an additional 1st prize. Special prizes from Mr. H. DEVERILL, Banbury; Mr. R. SYDENHAM, Tenby St., Birmingham; from Mr. W. J. GODFREY, Exmouth; and Mr. J. T. SIMPSON, were accepted; also the schedule of prizes for September, somewhat modified in regard to the Chrysanthemum classes, for October somewhat extended, and for November with added money. Eighteen members were elected, including four fellows; and the Dundee Chrysanthemum Society was admitted to affiliation.

DONATIONS TO GARDENING CHARITIES.—The result of two concerts held in Altrincham on Wednesday and Thursday, 1st and 2nd ult., under the auspices of the Altrincham Gardeners' Improvement Society, showed a balance in hand of £39 5s., which sum has been divided between the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund.

NATIONAL DAHLIA SOCIETY.—The following is a revised selected list of Cactus varieties of the Dahlia for the year 1898:—

Alfred Vasey	Juarezii
Annie Jones	Keyne's White
Annie Turner	Lady Penzance
Arachne	Mary Hillier
Beatrice	Mary Service
Bertha Mawley	Matchless
Britannia	May Pictor
Capstan	Miss A. Nightingale
Chas. Woodbridge	Mrs. A. Beck
Cinderella	Mrs. A. Peart
Countess of Gosford	Mrs. Barnes
Cycle	Mrs. Gordon Sloane
Daffodil	Mrs. H. Cannell
Delicata	Mrs. John Goddard
Earl of Pembroke	Mrs. Leopold Seymour
G. J. Deal	Mrs. Montefiore
Fantasy	Mrs. Wilson Noble
Fusilier	Night
Gloriosa	Regulus
Harmony	Robert Cannell
Harry Stredwick	Starfish
Iona	Tillie
Island Queen	Violet Morgan
J. E. Frewer	

WINDMILLS.—Mr. THOMAS CHRISTY kindly draws our attention to the manifold uses to which the principles of the windmill can be put. An illustrated sheet circulated by the Aermotor Company, Chicago, contains figures of forty-eight adaptations of the machinery as exemplified in deep well-pumps, pumps for delivering water in large or small quantities from rivers and lakes for household and manufacturing purposes. Machinery is likewise shown attached to aermotors for turning a feed-cutter, grinding corn, turning grind-stones, and various kinds of farm work. In this country the use of wind-motors seems to be mostly confined to milling purposes, and for little else; still, in a windy country, no cheaper driving method can be found than the air in motion.

"AQUATIC AND BOG PLANTS" (*Die Sumpf & Wasserpflanzen, Ihre Beschreibung, Kultur und Verwendung*: VON WILH. MÖNKEMEYER; Verlag VON GUSTAV SCHMIDT, Berlin, S.W.).—In addition to the American *Water Garden*, a publication has appeared in the German language, written by Mr. MÖNKEMEYER, the well-known curator of the Leipzig Botanic Garden, who has not only proved himself to be a successful gardener, but also a botanist of ability. The above-named work, treating of a subject the literature of which is scanty, and only to be found dispersed through various journals, supplies a long-felt want for amateurs in this branch of gardening. Of late years, especially, considerable attention has been paid to the cultivation of this interesting class of plants, so that the work now issued will be very

welcome. It comprises 190 pages, with 126 illustrations, drawn for the most part by the writer himself, which greatly add to the value of the book. Not fewer than 74 Natural Orders of flowering plants are found to possess representatives amongst water and bog plants; in fact, the compiler appears to have overlooked few that might be used for decorating natural waters and their margins, as well as those aquatic plants which will readily thrive in a living-room. Study and observation during many years have enabled him to bring together much material worthy of consideration. The book can be recommended to all who take pleasure in growing aquatic plants, and who are able to read German. It is very clearly written.

SOME ITEMS CONCERNING 1898.—As much information respecting horticultural meetings and exhibitions for the year just born as could be obtained before going to press will be found in the Almanack which is presented as a Supplement to our present issue. Most of the important events have been thus announced, it being customary in the case of influential societies to compile their programmes and schedules as early as possible. We give below a few particulars in addition to what are given in the almanac that may be interesting:—

THE MARKET GARDENERS', NURSERYMEN, AND FARMERS' ASSOCIATION, 32, King Street, Covent Garden, will hold their annual general meeting at a date to be fixed in July, and the executive will meet upon the first Tuesday following the quarter-days. As there have been frequent enquiries for the address of this Society, our readers will please note the above.

THE FARNINGHAM ROSE SOCIETY (writes Mr. Edmonds, the Hon. Secretary) will hold its annual exhibition upon the last Wednesday in June, or the first in July.

Mr. E. A. Newman, secretary to the EASTBOURNE HORTICULTURAL SOCIETY, states that meetings will be held on the second Tuesday in each month in the Natural History Society's Rooms, Lismore Road, at 8 P.M. There will be a competition among the members at each meeting. The date of the annual Chrysanthemum show has not been fixed.

THE ROYAL SCOTTISH ARBORICULTURAL SOCIETY will hold its annual meeting on January 26. A general meeting and annual excursion will take place at the end of July or beginning of August. The council will meet once in two months.

THE NATIONAL PINK SOCIETY (Midland section) and the WORKSOP ROSE AND HORTICULTURAL SOCIETY are in abeyance.

The annual show of the SOUTH SHIELDS AND NORTHERN COUNTIES CHRYSANTHEMUM SOCIETY will be held (writes Mr. Bernard Cowan) in the middle of November.

The annual meeting of the NATIONAL CARNATION AND PICOTEE SOCIETY (Northern section) will be held on January 29, when the date of the forthcoming exhibition will be probably fixed for the second Saturday in August. The secretary is Mr. T. Lord, Hole Bottom, Todmorden.

The exact date of the Annual Exhibition of the ROYAL HORTICULTURAL SOCIETY OF ABERDEEN has not been fixed, but it will probably take place on August 18, 19, and 20.

THE SCOTTISH HORTICULTURAL ASSOCIATION will hold meetings on the first Tuesday in each month, when papers will be read and exhibits made of new or rare plants, fruits, flowers, &c. Mr. R. Laird, the secretary, also informs us that this society will hold its great Chrysanthemum show on November 17, 18, and 19.

Mr. E. J. Ashelford, secretary of the SOCIETY OF JERSEY GARDENERS' writes, that his Society will hold monthly meetings on the second Thursday in the month, and the Council will meet on the fourth Thursday. The Floral Fête has been fixed for July 14, and the Chrysanthemum Show for November 9 and 10.

THE ROYAL NATIONAL TULIP SOCIETY will hold an exhibition in or near Manchester, and another one in London, but the dates have not yet been fixed (Secretary, Mr. Jas. W. Bentley).

THE NATIONAL AUBICULA SOCIETY (Northern Section) will meet at the Old Bull's Head, Market Place, Manchester, on Wednesday next, when the place and date for the annual exhibition will be decided.

THE GERMAN ROSE SOCIETY'S Annual Exhibition will be held at Cologne at the end of June. Novelties of German and foreign origin are solicited by the secretary, P. Lambert Frier.

THE RENFREWSHIRE GARDENER'S MUTUAL IMPROVEMENT SOCIETY will hold meetings on Jan. 12, 26, Feb. 9, 23, and March 9.

THE WAKEFIELD PAXTON SOCIETY will hold weekly meetings at the Paxton Room, Woolpack Hotel, Saturdays at 8 P.M. until March 5, when the annual general meeting will take place.

THE MANCHESTER HORTICULTURAL IMPROVEMENT SOCIETY will meet in the Memorial Hall, Albert Square, Manchester, at 7 P.M. on Jan. 13, 27, and Feb. 10, 24.

THE AYRSHIRE GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION will hold fortnightly meetings until May 5 in the Garrick Street Hall, Ayr, at 7.30 P.M. on alternate Thursdays.

A DIAMOND JUBILEE OAK.—Princess CHRISTIAN has planted in Windsor Park a tree to be known as the "QUEEN'S Diamond Jubilee Oak," the offspring of the QUEEN'S Jubilee Oak, planted in 1887. A tablet will bear the inscription, "This tree, raised from an acorn of the QUEEN'S Jubilee Oak, 1887, was planted, 1897, by H.R.H. Princess CHRISTIAN (Princess HELENA of Great Britain and Ireland) in commemoration of the sixtieth year of the reign of her Majesty Queen VICTORIA."

FLORA OF TROPICAL AFRICA.—It was only in our last number that we adverted to the publication of a part of the *Flora Capensis*, and in this week's number, the first of the year, it falls to our lot to have to mention the rejuvenescence of the *Flora of Tropical Africa*. Three volumes were issued up to 1877, and then the work came to an abrupt stop. How much the area and the material have increased since then it needs no research to discover. This is one of the reasons why the resumption of the work begins with vol. 7, in which the Orchids and the grasses, with other orders specially interesting to practical men will be comprised. The present part will be specially interesting to Orchid growers, in that it contains a large instalment of the Orchids from the pen of Mr. ROLFE. The publication of the Indian Orchids by Sir J. D. HOOKER, of those of S. Africa by Mr. BOLUS, and of Tropical Africa by Mr. ROLFE, will afford us a most valuable addition to Orchid lore, and do much to remove the perplexity and uncertainty in which we have been plunged.

THE WORCESTER BRANCH of the Gardeners' Royal Benevolent Institution recently held its annual general meeting at the Guildhall, Worcester. The report of the committee was adopted as very satisfactory, new officers were elected, and thanks accorded to Earl BEAUCHAMP and others who have materially assisted the Fund during the past year. During the past two years of the existence of the Worcester Auxiliary it has been able to provide the parent society with the considerable sum of £227 15s. The auxiliary nominated one candidate at the last election of pensioners, and the committee was pleased to announce that this gentleman was elected. Mr. J. HILL WHITE was re-elected Hon. Sec. and Treasurer.

RASPBERRIES ON CHRISTMAS DAY.—A correspondent in co. Meath informs us that he not only gathered Roses, Violets, and Primroses in his garden on Christmas Day, but a small dish of Raspberries.

PUBLICATIONS RECEIVED.—The *Weekly Budget* and the *Weekly Budget Supplement* for December 25, containing a store of seasonable literature for home or foreign readers.—*English Illustrated Magazine*, January, 1898.—*Annual Report of the Smithsonian Institution* (1), to June, 1893; (2), to June, 1894.—Two bulky volumes, full, as usual, of interesting information on scientific and general subjects; ethnological papers have a prominent place.

APPLE ROYAL SNOW.

DURING a visit to the Smithfield Cattle Show, held recently, we remarked the above Apple upon a stand belonging to Mr. W. Horne, Perry Hill, Cliffe, Chester; and subsequently Mr. Horne has obliged us by placing specimens at our service for illustration (fig. 4). Royal Snow is a Canadian Apple, and we are informed that one of Her Majesty's Jubilee commemorative gifts was a number of the fruits, sent by some Canadian fruit growers, who regard the variety with the highest favour. The fruit is above medium-size, being about 3 inches high, and nearly as wide, the halves unequal; colour intense but bright red, except on the shaded side, where the red streaks on a pale yellow ground are abundant. The whole of the exterior of the fruit is marked with small whitish spots. Eye closed, and set in a moderately deep and wide cavity; stalk slender, quite an inch long, and set in a deep funnel-shaped cavity, which, together with the base of the fruit, is covered with russet.

FIG. 4.—ROYAL SNOW APPLE.

The flesh is normally firm, juicy, crisp, of a peculiarly sweet, vinous flavour, and the fruit may be termed a first-class dessert Apple for Christmas and the New Year. It is Mr. Horne's intention to introduce the variety into this country, and we shall be interested to see how far it may prove adapted to our climate and methods of culture. The specimens we have seen, however, were grown in Canada, and the appearance and quality of the fruits must therefore not be taken to represent what fruits grown in this country may be expected to be like at this late season of the year, though this may possibly prove to be the case.

BOOK NOTICE.

FLORA PYRENÆA PER ORDINES NATURALES GRADATIM DIGESTA.—Opus posthumum editum, curante O. Penzig. Vol. i. MDCCCXC. Mediolani (Milan), Ulric Hoepli.

THIS is a book that will appeal to many interests. An authentic and carefully compiled list of the plants constituting the Pyrenean Flora is a boon that botanists and gardeners will cordially welcome.

Scholars, antiquarians, nomenclaturists (pardon the word) will all find interest, information, and some amount of amusement in these pages. Bubani was born in 1806, studied at the University of Bologna, managed to get involved in political disturbances, and in consequence was compelled to migrate from place to place, ultimately settling in Montpellier, where he enjoyed the friendship of Dunal, and first became imbued with his love for the Pyrenees and their flora. After a time he went back to Italy, but his native country proved no home for him, and he returned to the Pyrenees, and completed his flora, revising it from time to time.

Death overtook him in 1888, before he had the satisfaction of seeing his work in type. Now, owing to the pious care of Professor Penzig, the first volume sees the light. It is elaborated with painfully minute detail, and is preceded by a long Latin preface. In it the Pyrenees are divided into three botanical regions—the Atlantic, the Mediterranean, and the alpine region, the slopes of which face in the

direction of both oceans. Other sub-divisions are founded on the character of the soil—calcareous, saline, or otherwise.

Long disquisitions on nomenclature and synonymy follow, which are very interesting to the professed botanist, but not so much so to the amateur or to him who wants to know something about the plants themselves rather than the opinions of this or the other botanist on technical details of nomenclature. That system which enables the student to find what he wants with the greatest facility is the most generally useful. The name found, the student can arrange his details according to whatever system he prefers; and whilst anxious, as all should be, to avail themselves of the newest and best results of science, they need not waste their time on wrangles as to priority and bibliography—unless, indeed, their studies and predilections lead them to indulge in these researches. To mix up history with nomenclature more than is absolutely necessary is to confound two different things.

Bubani goes back to the classics, in the case of *Ulmus*, for instance, he quotes Homer, or, rather, *Ulmus vulgaris* is attributed to Homer as the authority, and Theophrastus is made responsible for *Ulmus*

montana. Most botanists would be more modest—they would say they did not know precisely what the authors in question meant. Their descriptions are not adequate, and they have left no plates, still less any authentic specimens, so that verification of references is impossible. A botanist like Dr. Bubani, who attributes any particular plant to them, must, it would seem, break that essential rule of nomenclature which forbids us from attributing to anyone that which he has not said.

But Bubani is not content with the Bauhins and Gesners of the renaissance, nor with the classical writers of Greece or Rome; he goes back to Holy Writ itself, and gives as the botanical authority for *Juniperus oxycedrus*, "Bibl. Sacr." We are not conversant with Hebrew, but we are quite certain that "*Juniperus oxycedrus*" is not mentioned in Holy Writ. Bubani, however, here, as always, scrupulously careful in his references, cites chapter and verse as follows—"Job, c. 30, v. 4." We turn to the authorised version, and we find, *l.c.*, "Who cut up Mallows by the bushes, and Juniper roots for their meat." A diet of Juniper roots does not sound appetising. We consult the revised version, and there we find the passage rendered:—"They pluck Saltwort by the bushes, and the roots of the Broom are their meat," the marginal rendering being, "to warm them," which seems much more likely. Bubani, in all probability, did not consult either of these versions of the Bible, but whatever version he consulted, it is at any rate clear that it is not judicious to wrest biblical names from their context, and apply them as they were never intended to be used. We do understand *Juniperus oxycedrus*, L. Sp., and we have the means of verifying the reference, but we can have no certainty as to the exact identity of the plant mentioned without any description, or figure, or specimen, by Job. Nevertheless, it is so convenient for the student to have these references ready to hand that it would ill become the critic to grumble because they are put out of their proper order.

No descriptions of species are given, but a full synonymy is supplied, together with details concerning the time of flowering, the nature of the soil upon which the plant grows, the localities where it has been found, and even the dates when particular specimens were collected. Notes and comments on the structure and affinities of the species are added, which reveal the accurate observation of the botanist. The student will be startled at the new names applied to old genera, or at the revivification of old names; for instance, on the authority of Pliny, *Viscum album* becomes *Stelin album*. As a full synonymy is given, and it is to be hoped a full index will also be forthcoming, these eccentricities may be pardoned, the more fully, as we are informed that the book was finished on December 15, 1873, about 2 o'clock in the afternoon, and therefore before the appearance of De Candolle's "*Lois*," or the publication of the *Kew Index*. Moreover, no one need follow Dr. Bubani's example.

One entry in the preface we cannot forbear quoting in the original. It tells how, on the afternoon in question, having finished his manuscript, he, with a full heart repeatedly embraced his daughter, that daughter who bore the name Felicia in commemoration of the friendship that existed between the author and Felix Dunal:—"Illico eo peracto gloriosus ad dilectissimam filiam Feliciam accessi (cui magistri et amici mei Dunal nomen imposui), eamque quam suavissime, jucundo corde iterum ac tertio osculatus sum." This was in 1873. In 1875, and in 1880 (July 25) the revision of the whole was repeated, and probably the osculation. Till the day of his death, in 1888, this process of revision and addition was carried on. It has fallen to Professor Penzig's lot to see the completed volumes through the press; he was precluded from making any change in the text, but the mere mechanical labour of supervising the impression of such a volume must have been exceptionally great. A volume of such learning and erudition, and one so accurately compiled, must, in spite of its eccentricities, have a warm welcome in the botanist's library.

A FRENCH GARDEN IN 1545.

(Continued from vol. xxii, p. 425.)

AREA OLITORIA.—This contains two beds, the "Salad" and the "Condiment;" first, the Salad-bed, Pulvinus acetarius: Lactuca, Lettuce; of this, some are sessile, some crisp, and others headed, called "Apple-Lettuce." The wild Lettuce some take to be the Endive, though "the Lettuce has the leaf of Chicory, yet it is broader, whiter, and less incised." Seris (in Grk.), Intybum (in Lat.), Scariola of the Italians, has two cultivated kinds, viz., the broad-leaved, Cichorion domesticum, and the narrow-leaved, or "Endive." The wild is called Cichorion, i.e., "Chicory;" the Picris of the Greeks because of its bitterness.

Hieracia major, called "yellow Chicory." As the author describes this as having a rough stem bristling with little spines, it would seem to be a Sow-Thistle, perhaps *Sonchus asper*; but he describes the garden Sow-Thistle under the name of Cicerbita (Lat.), which he says is commonly called "Du laceron." *Hieracia minor*, the author observes, the common people call Chicory, or Wild Endive; for it has leaves divided at intervals, tender little stems, green, on which yellow flowers are borne. It is not clear what this really is.

Malva, Mallows.—These were grown more for medicinal uses, on account of their emollient properties. He also describes the Tree-mallow "Rose d'Oultre Mer," i.e., the Hollyhock. *Bismalva*, "Des Guimauves," i.e., *Althæa officinalis*, or Marsh-mallow. He says of this, that it grows as high as the tops of the houses in Germany, and shepherds use its pliable stems as whips for the sheep! *Acanthus*, called mollis, because of the emollient nature of the root; and, though not a true "Acetarian," or Salad-plant, he associates it with the Mallows.

Oxalis, Wood-sorrel; *Portulaca* "Purpier;" *Bipinnella*, "De la Pimprenelle," *Poterium Sanguisorba*, or Salad Burnet; *Crithmum maritimum*, Samphire; *Olus cordum*, or cultivated Samphire, batis of Columella; it was called Empetrum, and the common people corrupted this name to "Sanpetram;" thence it came to be called St. Peter's Herb.

Asparagus.—There are two kinds, one the "fat" (altilis), or the garden sort. "It is very quickly cooked, then steeped in vinegar and oil; hence arose the proverb of anything which can be done very quickly, one says—'More quickly than Asparagus can be cooked.' The other kind is the wild, woody, and spiny species;" perhaps, *A. horridus* of the European rocky ground.

Cardamum (Grk.), *Nasturtium* (Lat.), "Du Cresson alenois," i.e., éloigné, Garden Cress; *N. aquaticum*, or cardamina, because the taste resembles that of Cardamoms, called by Latins, laver, or Sion; in French, "berle," by a transposition of the letters, thus—*Laver* becomes verla, then verula, hence Fr. "berle." Modern dictionaries render this "the Celery." (This reminds one of the word Revalenta, i.e., Erva lenta, framed from Ervum Lens, the Lentil). *Sisymbrium*, also called Cardamina, is another water-plant, which the author calls "Du cresson," but says there has been a great contention over it. It appears to be Water-cress; *Eruca*, "De la Roquette," *E. sativa*, L.

Senecio, "Du Senecon," Groundsell, "is most pleasant in salads." The flower, he says, vanishes into a pappos, which the people call "barbe dieu." It may be noticed that Ion Gardener also includes the Groundsel as a garden plant (*A Fifteenth Century Treatise on Gardening*, by Hon. A. Amherst).

Lapathum, "Parella," or "De la Parelle, or Patience," *Rumex Patientia*, L.—This is called *Hippolathium sativum*, or "Monk's Rhubarbe," by Gerarde (*Herb.*, p. 313). His figure resembles *Rumex Hydrolapathum*, though our author describes the *Hippolathium* of the Greeks as a distinct species. Wilson's (Fr. Dict.) gives *Hydrolapathum* as Patience. Lindley describes *R. alpinus* as the species in question. Of other kinds of *Lapathum*, our author mentions Sorrel, *R. acetosa*; and *L. acutum*, i.e., *Rumex acutus*, called in Piccardy "Surelle."

Borago, *Borage*, of which he says: "We use the blue flowers in the more refined salads." *Cerephyllum* "Cerfueil;" *Anthriscus cerefolium*, Chervil.

Tarco, "Du targon," the author does not know the plant, but says it has leaves like Hyssop. It is, of course, *Artemisia Taragona*, "Taragon;" and *Feniculus*, Fennel. This completes the list of salad plants.

THE CONDIMENT BED.—Cramben or Brassica, the Cabbage, of which there are many kinds, red, white, green, thick and thin-leaved sorts.

Atriplex, "Des Arroches," white and purple. These were species of *Chenopodium* and *Atriplex* as figured by Gerarde.

Molochia and *Atriplex maritima Mauritanis*, a shrub like *Halimus*, of which the leaves were cooked. Gerarde describes *Molochia* as a kind of Basil, called "Fish Basil," the seeds being received from Spain (*Herb.*, p. 549). Beta, "de la poree," the red kind was called Sicla, a second is white, and a third black. *Blitum*, described as the most insipid of herbs; it is a plant resembling Spinach, and called "des espinars," from its spiny seeds, probably *Amaranthus Blitum*.

Iasione, of Theophrastus, is a wild pot-herb, with a milky juice, bearing a white flower. Commonly called "Du liseron." This is *Convolvulus arvensis*, Bindweed.

Selinon (Grk.), *Apium* (Lat.), "Du persil Macedoine." This altogether resembles garden Parsley, but the scent is a little pleasanter. It was called *Petroselinum macedonicum* in the London *Pharmacopœa* until about 1760, when the use of it was dropped. Under *Selinon* the author adds *Atrum olus*, i.e., *Smyrnum olusatrum*, Alexanders; and *Petroselinum*, i.e., *oreoselinum*, or Mountain Selinum, garden Parsley.

Crocus, probably *Crocus sativus*, cultivated for Saffron. *Sinapis*, Mustard, white and black, the seed being called "Seneué." This was the name variously spelt in the Middle English, e.g., fourteenth century.

Porri.—Two kinds. The Leek and the Ampeloprasum, "because it grows among the Vines." It is *Allium Ampeloprasum*, L., our wild Leek. *George Henslow*.

(To be continued.)

ANTHRACITE COAL.

THERE was published in our issue for October 23 last a letter from Mr. Thos. Christy, which gave some interesting particulars relating to the use of anthracite coal in grates. The style of grate to which allusion was then made may be seen on reference to fig. 5. It has upright bars, and a pull-out frame at the bottom, the latter intended for use when more than ordinary draught is desired. It has a stone back, and probably many of our readers have seen similar ones. In this case, it was found that even when the damper at the bottom is quite closed, the draught is a very strong one. Wishing to turn this to account, Mr. Christy tried a quantity of anthracite coal, and it burnt perfectly, there being very little ash remaining when the fire is exhausted. Anthracite is moderate in price, is capable of producing intense heat, and lasts longer than any other coal. If certain grates ensure sufficient draught to cause this fuel to burn satisfactorily, its use will effect a considerable economy. Like coke, it will be found to burn with greater freedom in grates when broken into pieces about the size of a walnut.

HOME CORRESPONDENCE.

THE GALE.—This morning's gale (December 27), has blown down half of a beautiful Cedar on my lawn. One bough is about 18 inches in diameter, and a good length. Is it worth cutting into planks? *H. N. Ellacombe, Bitton*.

A WELL-TRAVELLED FLOWER.—Georgina Pitcher is a pretty and a melodious appellation. It may originally have been, and perhaps still is, the name of a very charming lady. It has, however, already become somewhat public property, as the appellation of a fine flower. *Chrysanthemum* Georgina Pitcher is a new yellow Japanese incurved, and is as good as solid. We heard the other day of the travels of flower Georgina, which was cut on November 8, was exhibited in a prize collection at the Westminster

Aquarium for three days, was next shown at Edinburgh, then on the 27th at the Westminster Drill Hall, and still came up smiling and fresh at the National Chrysanthemum Society's December show on the 7th inst. Is not that a record show attendance for one bloom. Evidently Georgina's "pitcher" is not easily broken. *D.*

CARNIVOROUS SLUGS.—Since the appearance of my note on the above, numerous correspondents from different localities have given various opinions. There seems to be little doubt they are strictly carnivorous, and I think there are few gardeners who would be inclined to destroy slugs they knew to be carnivorous, that they might encourage earthworms, great as the part is they undoubtedly have played in Nature, as drainers and aerators of the soil. Their presence is not of so much importance where land is artificially drained and under cultivation, being constantly broken up by trenching, limeing, &c.; under such conditions, it is a question if the good they are able to do can compensate for the mischief of trying to get anything and everything into their burrows. Surely there can be no question about the presence of worms on lawns and tennis-courts, and it is my intention to transfer some from the kitchen garden to "burrow" but not "cast." It does seem strange, that during alterations carried out here for several years in various parts of the grounds, we have never found any except in the kitchen garden, where they are very numerous, and always in the soil. I am assured the variety is the true *Testacella haliotidea*. May not those found so freely on the surface by some of your correspondents be *T. scutellum*, or *T. Mangei*? There are many theories about the shell and its position—is it not simply rudimentary? So far little seems to be known of the life-history of *Testacella*, even by students of the Mollusca. Yet it is generally acknowledged by all that they are strictly carnivorous, as the radula (or tongue) clearly indicates, by the complete rows of incisor teeth, as compared with the central molar teeth of the herbivorous section. The all-important question to horticulturalists is, do they live entirely upon earthworms or not? An authority on the subject writes me—"I am with you in believing that they are useful, and do not for a moment suppose that they feed exclusively on worms, but believe that they also feed on the larvae of many obnoxious insects." I have much pleasure in sending you living specimens of *T. haliotidea*, also photographs of the "radulas" of carnivorous and herbivorous slugs. *M. Webster, Beckenham*. [We shall shortly publish an illustrated article on the subject. *ED.*]

— This species is common here—Pembrokeshire, although Mr. Webster said that he never came across any in South Wales, or saw one of them out of the ground (see *Gardeners Chronicle*, p. 314, vol. xxii). For my part, I can state that I have found more of them on the surface of the ground than below it, and I could find one any day if I sought for it. It was only last week that I came across one of the slugs with its head thrust into a live snail, and I have often seen them devouring worms, but not snails. *W. Cavill, Penally*.

FRUIT JUDGING.—There is one point in "Ayrshire Lad's" note (p. 404), which well deserves to be considered by judges of fruit, viz., that of ripeness when shown. When the schedule distinctly says it is necessary that the fruit shown shall be ripe, judges have no choice in the matter; but the preference for ripeness (even when out of season) is carried to excess in many cases where it is not demanded by the schedule, and where ripeness is a positive defect. I need only instance the single-dish classes at the fruit show held under the auspices of the Royal Horticultural Society at the Crystal Palace Time and again I have seen fruits that were ripened out of season placed before others that were in every way of better quality but not ripe. Which is the most valuable dish, say, of Marie Louise Pear, dead ripe in September, or a similar dish at the end of October or in November? We have plenty of good summer Pears, but not so many as the year advances, and to turn a late variety into an early one is doing quite the wrong thing. It is generally known, too, that the best-flavoured Marie Louise Pears are those grown in the open, where they have no artificial aids to ripening. It may be said that to lengthen the season of a good fruit is a gain, and grant that, but do not think that this is a point which should weigh with judges. I have only instanced one variety, but it is not for want of others; the circumstance is common, and I might just as well have selected the variety Pitmaster Duchess. *Cornubian*.

PRUNING APPLE AND PEAR TREES.—Mr. Kettle having misrepresented (p. 448) my remarks made on the pruning of Apples and Pears, I beg the editor's permission to reproduce them. The cultural directions which Mr. Kettle has misrepresented, and then used as a basis for a somewhat lengthy criticism are:—"Upon the manner in which this simple though important operation is carried out depends almost entirely the building up of fruitful and consequently profitable specimens, whether they be standards, pyramids, bushes, or espaliers. However, it would be better to let the trees go unpruned than to trust an unskilful man with the pruning—that is, to allow a man having no clear object in view in operating on young or maiden trees. The formation of large fruit-bearing trees, of whatever kind, in as short a time as possible, is the wish of all who possess fruit-trees; therefore, the young leading shoots of standard pyramid trees and bushes, should be pruned-back to within from 5 to 9 inches; each of these pruned-

being furnished with three wood-buds, and these having pushed into free growth were pruned back to from 5 to 9 inches last winter, each pruned-back shoot producing from three to five growths this year, thus giving us individual trees with from nine to fifteen growths from "last year's cut-back maidens;" and the only pruning which I advised to be done to these trees was, "Where likely to become crowded, or to cross each other in growth, to cut back to within 2 inches of last year's wood." Maiden fruit-trees, of whatever kind and shape, must be pruned-back in the manner mentioned above, in order to lay the foundation of well-balanced, fruitful specimens "in as short a time as possible." Mr. Kettle says, "if you have cut back either standards or bushes, they will have at least nine to twelve growths;" adding "if they are pruned back to 5 or 9 inches, and make three to five more growths, you will get from twenty-seven to sixty branches within 5 to 9 inches of the main stem," which in his humble opinion is far too many.

FIG. 5.—ANTHRACITE COAL GRATE. (SEE P. 12.)

back shoots will produce from three to five growths next spring. These—assuming that we have last year's cut-back maidens to deal with now—where likely to become crowded, or to cross each other in growth, should be cut back to within 2 inches of last year's growth. This will result in the formation of fruit-buds, in addition to promoting a symmetrical shape in the individual trees. Once young trees of this description have borne a fair crop of fruit, they will require very little annual pruning beyond the cutting out of a branch here and there where likely to cross each other, repeating the operation more or less every year as may be called for, until the trees acquire the desired size." Any reader who may take the trouble to read the above in connection with Mr. Kettle's comments thereon will easily see that he has quoted certain sentences therefrom without giving the context. Mr. Kettle appears to forget that "maiden trees" are not furnished with "six to eight growths to the main stem." Let us suppose that maiden trees, i.e., stocks grafted in the spring of 1896, each scion

Having made the above *pro contra* statements, for which Mr. Kettle himself is solely responsible, he is willing, however, to "grant that the badly-placed shoots can be taken off," adding, "but the writer does not advise this, but to cut back (such misplaced growths) to within 2 inches." What is this but taking off? Moreover, any shoots (two at the most) proceeding from the said 2 inches of lateral growth, should be pinched hard back the following summer, with a view to producing fruit-buds. Mr. Kettle goes on to say "he has yet to see a deciduous tree made shapely and fruitful by severe pruning." Well, he must be very young, and consequently inexperienced! I have frequently advised this in the case of neglected trees in orchards and gardens, in order to secure shapely and fruitful trees. If a young Apple, Pear, or Plum-tree is left to itself, i.e., not pruned at all, the pushing into growth of the buds or the upper portions of the individual shoots at the expense of those lower down will occur until the exuberance of growth is checked by the trees bearing a good crop of

fruit; but, in the meantime, the few leading shoots attain to a greater height from the ground before they branch out than is desirable. Mr. Kettle says in concluding his note that "root-pruning is an operation entirely unnecessary (?) so long as the tree has room to extend its branches." The reverse of this being the case, I am inclined to think that the words "so long as the tree has room to extend its branches," must be a misprint for, so long as the tree yields satisfactory crops of fruit. [No.] Mr. Kettle cannot have read his *Gardeners' Chronicle* carefully during the past twenty years, or he would have known that I have been an advocate of the "extension system" of pruning and training fruit-trees during that period of time. In pruning horizontally-trained wall or espalier-trees of the Apple, Pear, and Plum, after the first pair of branches—extending right and left from the tree—is secured, the leading upright-central shoot should be cut-back to within 12 or 15 inches of the pair of horizontal branches of the current year's make at pruning time every year, until the top of the wall or espalier wires is reached, in order to obtain a new pair of branches every year. I have tried to secure two pairs of horizontal branches annually, but only with partial success; as some years only three buds, two on one side and one on the other, would push into growth, thereby rendering the insertion of a "bud" in the main stem, close to the dormant bud, necessary, in order to prevent a blank occurring in the building up of the tree. *H. W. Ward, Rayleigh, Essex.*

VITIS COIGNETIÆ.—At Culford Hall, near Bury St. Edmunds, is growing a fine young Vine under the above name, which is the same way as that illustrated in your issue for October 30 (p. 305). It was planted out during the past spring to cover a portion of a wall facing west, and close to the north wall of the garden, so that it is well sheltered from east and north. Here it has grown vigorously, having made eight or ten young rods, each as strong as an ordinary pot-Vine prepared for fruiting, and about 10 feet long. At the time of my visit a few weeks ago, the large claret-coloured leaves were very effective, and the canes were well ripened. The Vine will become a very striking object in autumn, and the coloured leaves remain upon the plant later than those of any other deciduous climbing foliage-plant. *J. C. T.*

EARLY POTATOS.—In the efforts to obtain new Potatos as early as possible in the year, various methods are adopted. The earliest are grown under glass in Peach-houses, vineries, or heated pits; then follow those from colder frames. Succeeding these will be those grown at the foot of a south wall, and then those on a warm, south border, between the rows of Peas, the stakes used for the latter forming a capital shelter for the Potatos. I used to grow for the first crop the old Myatt's Ashleaf in pots placed in a newly-started Peach-house. Some time previous to potting, the tubers were placed in single layers in shallow boxes containing a little leaf-mould. The boxes were then placed in slight warmth, and occasionally sprayed over with water. When growth had commenced, all the weakest were rubbed off, leaving three of the best and strongest to each tuber. The 10-inch or 12-inch pots were then drained and half filled with a rather light, moderately rich soil, and three tubers planted in each. They were then lightly watered, and afterwards placed in as light a position as could be given them. The plants should be earthed-up when the tops have grown 8 inches, using soil that has previously been warmed to the same temperature as that of the house in which they are growing. Great care should be taken not to over-water them, for if the soil be kept too wet, failures are sure to follow, and a close stagnant atmosphere will be equally injurious. *H. M.*

ROYAL SOVEREIGN STRAWBERRY.—This variety did very badly with me last spring as a forcer for market supply, and was nowhere as against Laxton's Noble and Sir Joseph Paxton. It had long straggling fruit-stalks, and enough leaves on one plant to serve for two. Out-of-doors it was the same. I got my plants from a trustworthy firm, and I should be glad if some market cultivators would record their experience of this much vaunted variety. *W. Carill, Penally.*

SULPHURING VINES.—Having repeatedly read in "Answers to Correspondents" your caution against burning flowers-of-sulphur in vineries that have been pruned, I take the liberty of informing them that this may be done with perfect safety. I have been

in the habit of burning sulphur in my vineries for the past fifteen years, and have never seen one single instance of injury to the Vines, although the quantity of sulphur is never weighed, or the cubical area of the house measured. Our vineries are all about one length, but they vary in height; in a house with area of about 6000 cubic feet we use a 32-sized potful of sulphur (should suppose this would be about 5 lb.), but I do not believe any injury would be done to the Vines if double the quantity were used. *Experience.*

ABNORMAL TEMPERATURE.—It may be interesting to your readers to know the unusually high temperature recorded here on Saturday, 18th ult. On a small post, at about a foot from the ground, and quite in the open, a thermometer showed 74° at 11.30 A.M., and remained so for half-an-hour. *H. L. Wall, Roselands Nursery, Eastbourne.*

A FRENCH GARDEN IN 1545.—The plant referred to as a Hollyhock is *Tagetes patula*. It is still known in France as "Gillet d'Inde," and is mentioned in *La Maison Rustique* as "Gillet d'Inde ou Turquie," which *The Countrée Farme* (1600) translates "Indian Gilloflower," giving at the same time the Latin names, "*Flos Petilius*" and "*Ocellus indicus*." "*Coquelourde*" includes "*Flos Jovis*," "*Fleur de Jupiter*," or "*Lychnis Flos Jovis*." See Vilmorin's publications, where *Anemone pulsatilla* is referred to "*Anemone*," and the other to "*Coquelourde*," which is practically synonymous with the English "*Cockle*" as applied to flowers. *R. P. B.*

DIOSPYROS KAKI.—Mr. Burbidge suggests, *Gard. Chron.*, p. 441, last vol., that in the south and west, near the sea, the plant might thrive and fruit in the open air. I have had it here for more than ten years, and it has often ripened its fruit; and three years ago I had over forty fruits on it, most of which ripened well. It has also fruited at Tortworth on quite a young tree. I wonder it is not more grown. It is quite hardy, and even as a foliage-plant it is well worth growing. *H. N. Ellacombe, Bitton.*

A HALL FOR HORTICULTURE.—I do not remember ever having seen it stated by anyone but Mr. Divers that the National Chrysanthemum Society "could not succeed apart from its music-hall associations." I have gone the length of stating that the National Chrysanthemum Society cannot possibly carry on four flower-shows in a year—covering the whole of the Chrysanthemum season—without some such assistance as that rendered by the Royal Aquarium. One fact cannot be disputed—that it was not until the Borough of Hackney Chrysanthemum Society became associated with the Royal Aquarium that it developed from a local society into one of national importance. Its growth without pause during the entire period of that association has been and is still phenomenal. Despite the large space the building affords, I find Mr. Divers and others complaining of its crowded condition, and of the difficulty experienced in seeing the flowers, and they suggest as a substitute a horticultural hall. It would require to be as large as St. Paul's Cathedral to meet the requirements of the National Chrysanthemum Society. The people go to the Aquarium despite its associations, and it is gratifying to notice an increase in the attendances at the September, October, and December exhibitions. Mr. Divers and others overlook the fact that hundreds who attend the Aquarium see, probably for the first time, fine displays of flowers, and in this way a new-born interest is aroused in many who are thereby induced to cultivate. I get substantial proof of this in various ways. I am further convinced that if the rank-and-file of the membership of the National Chrysanthemum Society were polled, there would be an overwhelming vote in favour of continuing the shows at the Aquarium. The entertainment, so much denounced by some, is a great source of attraction to numbers in the gardening profession. They meet friends there, they can talk together, and smoke, and drink if they please; there is warmth, and light, and life—and these are to them sources of enjoyment. The practical man notices these things; the sentimentalist and the theorist overlooks them. It is true the Edinburgh Chrysanthemum show was a great success, so was that at Birmingham; but at Manchester and other large centres they were dismal failures. Let Mr. Divers consider what has been the fate of large flower-shows in London during the past twenty years. The Crystal Palace is held to be a model place in which to hold a flower-show; the exhibitions formerly held there, with other attractions thrown in, failed to pay. Where are the great shows of the Royal Botanic

Society? Did the venture of the Royal Horticultural Society at the Agricultural Hall a few years ago answer? The reply is, they have not gone there since. All the prestige of the Royal Horticultural Society cannot induce the people to go and see a show in their Chiswick gardens; they cannot get their Fellows to the Drill Hall meetings. The series of fine exhibitions held at Earl's Court in 1892–93 failed to draw; as did those at Olympia two years ago. The National Rose and the National Dahlia Society would in all probability collapse were it not for the subsidies furnished by the Crystal Palace Company. Let the National Rose Society run a show in London without any outside financial assistance—I should predict financial failure. London cannot, and must not, be placed on a level with Edinburgh. There is a social homogeneity about the latter city lacking in the former. There is in London a vast variety of counteracting entertainments, not only in the centre, but all round the circumference; and there is scarcely an important suburb but has its own society and annual exhibition of Chrysanthemums in November. Apart from the difficulty of finding a place large enough to hold a show like that the N. C. S. holds in November, the cost of it would be enormous, the risk very great. The best experience which could come to Mr. Divers would be in taking charge of the details of a large flower show in London, and I am confident he would see things in their true light, and understand better why I, who have had a great deal to do with London flower shows in the past, have been led to think an exhibition held by the N. C. S. anywhere else but at the Aquarium would be incurring a heavy financial risk, I for one shrink from undertaking. (The figures 4000, third line, centre column, p. 449, should read 5000.) *Richard Dean, Ealing, W.*

LAW NOTE.

COOKSON v. SAMSON.

A CASE of considerable interest to bee-keepers was heard before His Honour, Judge Sir D. L. Selfe at the County Court, Romney, Kent, on August 19 last, in which the plaintiff, Mr. C. D. Cookson of Blean, Canterbury, sued the Rev. G. H. Samson of New Romney for damages for misrepresentation, or in alternative for breach of warranty. Mr. Percy Maylam, solicitor, Canterbury, represented the plaintiff; and Mr. F. C. Drury, barrister, instructed by Mr. Bracher of Maidstone, defended.

In view of its importance to the bee industry generally, and the more or less conflicting reports of the case given in the daily press, we have been at some trouble to secure a special and reliable account of the proceedings (from the reporter's notes) for the benefit of our readers, which will be found below. This explanation is made in order to account for the delay in publishing particulars; not from lack of interest, but as affording a reason why we did not acknowledge the scores of press-cuttings kindly sent by various readers for insertion in our pages.

In opening the plaintiff's case, Mr. Maylam stated that the plaintiff had purchased of the defendant twelve stocks of bees, which defendant had offered for sale in the *British Bee Journal* for October 22, 1896, as being "strong stocks of healthy selected grain black bees," the amount of purchase-money for the twelve stocks, and certain bee-keeping accessories, being £16. The plaintiff had bought the bees on the strength of the representation that they were healthy, as stated in the advertisement, and confirmed by subsequent verbal statements; whereas they were infected with foul brood, a bee-disease of a very serious kind, as being extremely destructive and infectious. Mr. Maylam explained the nature of the disease, and quoted from the leaflet issued by the Board of Agriculture on the subject. As a consequence, the whole of the stocks bought had died a short time after the purchase, having previously infected with the disease bees which had belonged to the plaintiff, and were healthy before the purchase in question from the defendant. He submitted that the defendant was liable, in the first instance, in contract, as the advertisement and representation amounted to a warranty, and argued that a bare representation or asser-

tion as to the quality of goods might amount to a warranty. Secondly, he (Mr. Maylam) submitted that the defendant was liable in tort for misrepresentation, on the ground that, being a certificated expert, he must have been aware of the state of the bees when he represented them as healthy, and evidence would be produced to show that he had been warned that foul brood existed among his bees before the sale took place.

His Honour the Judge, in giving his decision, said: I am of opinion that no case of misrepresentation has been made out, and am surprised that it has been brought. It appears that the defendant had no knowledge that the bees were infected with foul brood, and being an expert he considered his opinion as good as that of Mr. Hamlyn-Harris. With regard to the question of warranty, it is plain that the bees were described as healthy in the advertisement, and we have the statement of the plaintiff that they were described as healthy to him, and he bought them relying on that assurance. On the first occasion the plaintiff did not examine; on the second he did; but only to the extent of ascertaining how many frames were covered with bees. It appears to me that the defendant did sell them as healthy bees, and that the plaintiff relied on the misrepresentation of the defendant that the bees were healthy; therefore there has been a warranty. Now, we have seen they were seriously infected, therefore there has been a breach of warranty, and the verdict will be for the plaintiff for the amount claimed, with costs.

Obituary.

MR. JAMES BROWN.—It is with much regret that we record the death, in the sixty-fifth year of his age, of Mr. James Brown, gardener to Capt. D. Moray, of Abercainey, Perthshire, on December 22, after over forty years' service there. The deceased was one of the best-known gardeners in Scotland, and he was for many years a keen and successful exhibitor of vegetables and hardy fruits at the leading horticultural shows at Perth, Dundee, Edinburgh, and Glasgow; and owing to his extensive knowledge and to his well-known conscientiousness in awarding prizes, he was frequently asked to officiate as judge at such shows. His work at Abercainey and his devotion to his employer's interests, were duly appreciated by his gallant employer. Mr. Brown succeeded his father-in-law, the late Mr. James Arnot. Abercainey was the home of the McIntoshes of Dalkeith and Drumlanrig Gardens, and is one of the most beautiful of Scottish seats. *M. Temple, Carron, N.B.* [The gardener's cottage was figured in our issue for February 17, 1894. Ed.]

SOCIETIES.

ROYAL HORTICULTURAL. Scientific Committee.

DECEMBER 14.—Present: Dr. M. T. Masters (in the chair) Mr. Michael, Rev. W. Wilks, Mr. Sutton, Prof. Church, and Rev. G. Henslow (Hon. Sec.).

Cypripedium, Monstrous.—With reference to the specimen sent to the last meeting by Mr. Veitch, Dr. Masters reports that the lip was wanting, but the dorsal and ventral sepals as well as the lateral petals were normal; both stamens were present, but only two carpels, standing in an antero-posterior position.

Tuberous Growths on Vines.—Mr. S. T. Wright sent some gall-like structures taken from Vines in the large vinery at Chiswick. He observes that "many of the old and young rods are similarly malformed at their base. It does not appear to affect the health and vigour of the rods. In all the malformations grubs or maggots are present; but neither moths nor weevils have been seen in the house." Mr. Michael pronounced the grubs to be coleopterous, but they were not likely to have been the cause. Professor Church undertook to examine them chemically. There was no apparent structure in them beyond a mass of cellular-tissue with a corky exterior surface.

Hellebores Diseased.—Some badly diseased plants were received from Mr. F. W. Burbidge, Botanic Gardens, Dublin. They were submitted to Kew for examination. The report was as follows:—"Phoma effusa, Desm., is the name of the fungus attacking the Hellebores. The diseased portions

should be removed and burned, as at this season the fungus is producing myriads of spores, which live as saprophytes on humus in the soil for some time before they are capable of acting as parasites. The Hellebore shoots of next year will be infected by these spores. The above alternation from a parasitic to a saprophytic mode of life enables the fungus possessing one form of fruit only, as in the present instance, to tide over the period during which its host-plant is not actively growing. Spraying with a solution of potassium sulphide (1 oz. to 3 gal. of water) when the leaves first appear next season would, to some extent, prevent the chances of inoculation from floating spores."

Holly with Red and Yellow Berries.—Mr. Ch. Turner, Slough, sent some sprays, on which he remarks, "They are cut from a large tree which retains its berries for two years. The berries are yellow in the first year, but change to red in the second year." As no seasonal break was distinguishable between the group of yellow and that of the red berries below it on the same stem, some doubt was expressed, and some further information desired. This Mr. Turner has kindly promised to furnish.

NORTHAMPTONSHIRE CHRYSANTHEMUM.

DECEMBER 15.—The annual meeting of this Society was held at the Racehorse Inn, Abingdon Square, Northampton, on the above date, under the presidency of Mr. F. Perkins.

The receipts for the year were stated in the report to have been £160 12s. 9d., and there was a balance of £5 6s. 11d. on the year. The report was adopted, and then the election of officers was proceeded with. Mr. Labouchere, M.P., was chosen president, and the whole of the vice-presidents were re-elected *en bloc*, with the addition of Mr. Cole, of Hazelwood Road. Mr. E. Draper was re-elected hon. secretary and sub-treasurer.

NEWCASTLE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT.

DECEMBER 21.—The monthly meeting of this Society was held at 25, Westgate Road, Newcastle-on-Tyne, on the above date, Mr. BULLOCK presiding.

This being the first of a series of competitions, certificates were offered for the best stand of cut flowers of Japanese Chrysanthemums, distinct varieties. There were five entries, all of which were of exceptional merit. The best were shown by Mr. MUNRO, Enfield, Gateshead; and Mr. ROME, Oakwood, Wylam-on-Tyne.

Special certificates were also awarded to Mr. LARKE, of North Dene, Gateshead, for a large and beautifully-arranged vase of Chrysanthemums; and to Mr. HALL, Heathdale, Gosforth, for an excellent stand of Chrysanthemum Niveum. A general discussion took place on the "Cultivation of the Chrysanthemum," in which many of the thirty-five members present took part.

SCOTTISH HORTICULTURAL ASSOCIATION.

DECEMBER 21.—A *conversazione*, attended by about 150 ladies and gentlemen, was held in the Royal British Hotel, Edinburgh, on Tuesday evening, December 21, by the Scottish Horticultural Association. The guests were received by the President (Mr. Todd), who was accompanied by Mrs. Todd, in the new dining-room, the centre table of which was decorated with Chrysanthemums. The chief purpose of the gathering was the announcement of the allocation of the surplus funds derived from the recent successful Chrysanthemum show held in the Waverley Market, which, it had been resolved, should be devoted to charitable purposes. In the course of the evening the President intimated the Association's decision. Addressing the gathering, he said they were assembled to celebrate the harvest-home of the recent Chrysanthemum show. That show was one of the most successful ever held in Edinburgh. After all expenses had been paid, there was a balance of £250. They had resolved to give £100 to the Royal Infirmary pavilion scheme, £50 to the Royal Hospital for Sick Children, and, as their exhibition depended largely for its success on horticulturists all over the kingdom, £50 would go to the Gardeners' Orphan Fund, and £50 to the Gardeners' Royal Benevolent Institution. The Treasurer of the Association (Mr. McKenzie) then presented the Lord Provost with a cheque for £100 for the Infirmary pavilion scheme, and also handed a cheque for £50 to Mr. Cook, C.A., Treasurer of the Sick Children's Hospital. The donations were suitably acknowledged.

DEVON AND EXETER GARDENERS'.

DECEMBER 22.—An interesting lecture on "Insectivorous Plants" was read by Mr. NORMAN GILL, gardener at Tremough, Penryn, Cornwall, on the occasion of the meeting on the above date. He said that while these plants were known to botanists in the last century, public attention was not directly called to the peculiar properties of Sundews, Butterworts, and Bladderworts, until Darwin, in conjunction with Sir J. D. Hooker, awakened an interest in the subject. We could only muster twelve indigenous species and two sub-species of insectivorous plants; the more notable *Nepenthes*, *Sarracenia*, &c., coming from foreign lands. The Sundew, however, was a good type, and showed

clearly enough how such plants captured insects. The leaves were fringed and covered with outstanding, bristling, crimson hairs, each of which was furnished at the tip with a globule of viscid matter, and when an insect came in contact with this fringe it was held fast, the hairs began to incline backward and inward to the centre, carrying the captive with them. The secretion resembled in its effects the gastric juice of the human stomach, and performed the work of digestion for the plant, extracting and absorbing the food, which, through this channel, was conveyed to the leaf first, and by it to the plant itself. When the process was complete, the leaf-hairs were extended as before. Some of those plants had scarcely any roots, the natural functions of these organs, by disuse, having ceased to be used for feeding the plant. When an insectivorous plant was fed by nitrogenous manure at the roots, its insect-eating propensity became languid and feeble, showing that these plants had an alternative means whereby they lived. It was assumed, and held by many botanists, that some plants had out-lived the insectivorous stage, and had become root-feeders; *Parnassia palustris* being mentioned as an instance of this kind of reversion. An instructive discussion on the root action of the *Sarracenias* followed. Several good specimens were on the table to illustrate the paper.

READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

THE last fortnightly meeting for the season 1897 was held recently in the Abbey Hall, and was presided over by the President, Mr. C. B. STEVENS. A very large number of members attended, to hear a paper entitled "A Chat about Chrysanthemums," by Mr. H. J. Jones, of Lewisham, the well-known exhibitor and grower.

The paper was given in a very interesting and "racy" manner, and contained much practical advice and many illustrations. The paper was divided into several sections, such as propagation, composts, potting, manuring, watering, insects, housing of the plants, exhibiting, &c.

FIG. 6.—SEED VESSEL OF EUCRYPHIA PINNATIFOLIA.

A splendid exhibit of flowers, &c., by the members greatly added to the interest of the meeting. Messrs. SUTTON & SONS sent some beautiful specimens of Cyclamens, including Sutton's Salmon Queen, Vulcan, White Butterfly, &c. Mr. TOWNSEND, Sandhurst Lodge Gardens, staged some grand plants of *Primula obconica*. Mr. BRIGHT sent dwarf plants of *W. H. Lincoln Chrysanthemum*, showing the decorative value of plants grown in 3-inch pots; and Mr. BRADLEY, Tilehurst Nurseries, exhibited cut blooms of Chrysanthemums, and a basket of Mushrooms. Mr. WOOLFORD, East Thorpe Gardens, contributed beautiful plants of *Begonia Gloire de Lorraine*.

FLAX PRODUCE IN IRELAND.

It is interesting to learn that a note of improvement has been sounded in the sister isle. Thus we are told that capital is finding its opportunity up and down the country; railway rolling-stock is being over-hauled and brought up-to-date; hotels are being either improved, extended, or built, on likely routes for tourists; and, though last, not least, attention is being paid to improvements in Flax culture, with the view of reducing the amount imported from abroad—extending an industry which is of prime importance to the North of Ireland more especially. In this connection we are told by an authority that among the Flax shown at Belfast the other day was some from Dromore, co. Down, grown under the supervision and direction of an expert Flax farmer, brought from Holland by Messrs. William Barbour & Sons, of Hilden—the large-linen thread manufacturers, whose services had been placed at the disposal of some of the farmers in the Dromore and Dromata districts who were in the habit of growing Flax every year, and who could be prevailed upon to

try for themselves if there was any advantage to be derived by following the customs adopted in other countries in reference to Flax-growing. The experiments show that by greater care and attention on the part of the farmer and the scutcher, Flax would be grown at a much more remunerative rate than at present, and that it would not be necessary to import so much every year from the Continent. Heaven helps those who help themselves, truly. The Cork butter market has felt all this—other folks may safely follow the example; and so, by-and-by, the sight of so-called "picturesque beggars" infesting all popular routes and "show places" may become as rare as it at present has to be deplored. Work is a fine humaniser and breeder of content.

EUCRYPHIA PINNATIFOLIA.

THIS very handsome hardy shrub is not so well known as it should be. Perhaps now that it has ripened its fruits it may become more common. The capsules illustrated (fig. 6) came from the garden of Miss Breton, of Sandhurst, Berks, a lady, who by her love of plants, enables them to overcome the disadvantages of a site that is not in all points an ideal one for gardening. The fruit is a capsule, bursting along the partitions (septicidally), and each of the ten or twelve cavities contains two rows of pendulous seeds.

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM INSIGNE VAR. SANDERÆ.

A PLANT of this variety, a small portion of the Pickering Lodge plant, is now coming into flower in the Tyntesfield collection. Mr. Hardy intends to exhibit it at the next meeting of the Royal Horticultural Society, January 14, so perhaps the writer of last year, who knew more of our plants than we do ourselves, will have an opportunity of explaining the difference between this and the true variety. *T. S.*

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

THE following summary record of the weather throughout the British Islands for the week ending December 25, is furnished from the Meteorological Office:—

"The weather during this week was generally fine, dry, and cold, over Great Britain; a good deal of fog prevailed at times over the inland parts of England. Over Ireland the conditions were, as a whole, fine, dry, and mild.

"The temperature was below the mean in Scotland, and nearly all parts of England, but just equal to it in 'England, S.' and 'S.W.' In the north and east of Scotland the deficit was as much as 5°. Over Ireland the average for the week varied from 2° to 4° above the normal. The highest of the maxima was recorded on the 19th over England, but on the 25th in most parts of Ireland and Scotland; they ranged from 55° in the 'Channel Islands' and 51° in 'Ireland, S.' to 47° in 'England, E.' At some of the northern Scotch stations the daily maxima were on several occasions below 32°. The lowest of the minima were registered between the 21st and 24th, and ranged from 12° in 'Scotland, E.' (at Nairn), 14° in 'Scotland, N.' (at Lairg), and 19° in the 'Midland Counties' and 'Scotland, W.' to 32° in the 'Channel Islands,' and 34° in 'Ireland, S.' The mean of the minima was as low as 17.4° at Nairn, and 19.2° at Lairg.

"The Rainfall was entirely absent from most districts, but slight amounts were measured at some of the western and northern stations towards the end of the week.

"The Bright Sunshine exceeded the mean in all districts excepting 'England, N.E.' and 'Scotland, W.' the excess being very large in the south and south-west. The percentage of the possible duration ranged from 47 in the 'Channel Islands' and 45 in 'England, S.' to 36 in 'England, S.W.' 25 or 26 in Ireland, 15 in 'Scotland, N.', and to 14 in 'England, N.W.' and 'Scotland, W.' The highest percentages recorded at any individual station were 70 at Jersey, 61 at Westbourne, and 59 at Hastings."

MARKETS.

COVENT GARDEN, DECEMBER 30.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

POTATOS.

Holidays have interfered with trade as usual. Second-class Potatoes have again advanced a shade:—Up-to-date, 95s. to 115s.; Maincrop, 85s. to 110s.; Saxons and Bruce, 85s. to 100s.; Dunbar Maincrop, 130s.; Blacklands, 75s. to 80s. per ton. Belgian and Dutch Ware, 3s. to 3s. 6d.; German do., 3s. 6d. to 5s. per bag of 50 kilos. John Bath, 32 and 34, Wellington Street, Covent Garden, W.C.

SEEDS.

LONDON: December 29.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that to-day's market, as is always the case at the turn of the year, presented quite a holiday appearance, and quotations all round are consequently without any material alteration. The absence this past autumn of the customary speculative dealings in Clover and Grass-seeds naturally leaves a large consumptive sowing business to be done in the approaching spring. Full prices are asked for Mustard and Rapeseed. Blue Peas and Haricot Beans also keep very firm. In Birdseeds there is but little doing. Linseed steady.

FRUIT AND VEGETABLES.

GLASGOW: December 29.—The following are the averages of the prices at this market during the past week:—Pears, 3d. to 8d. per lb.; Apples, 2d. to 4d. do.; Plums, 4d. to 6d. do.; Tomatoes, Guernsey, 4d. do.; do., Scotch, 5d. to 7d. do.; Grapes, home, 2s. to 3s. do.; do., foreign, 4d. to 6d. do.; Cabbages, Scotch, 6d. per dozen; do., late, 1s. to 1s. 2d. per dozen; Cauliflowers, 1s. to 2s. per doz. bunches; Parsnips, 4s. to 4s. 6d. per cwt.; Herbs, assorted, 1d. to 2d. per bunch; Leeks, 1s. 6d. to 3s. 6d. per dozen bunches; Mint, 6d. per bunch; Onions, Dutch, 2s. 9d. to 3s. per bag; do., Portugal, 5s. to 6s. per case; Parsley, 9d. to 1s. per stone; Potatoes, best, 8d. to 9d. stone; Carrots, 2s. 6d. to 3s. 3d. per bag; Artichokes, 3s. 6d. per sieve; Cucumbers, 8s. to 9s. per dozen; Lettuces, round, 6d. to 1s. do.; do. Cos, 6d. to 8d. do.; Radishes, 8d. to 9d. per dozen bunches; Horseradish, 1s. 6d. to 2s. per bundle; do., French, 4s. 6d. per stone; Mushrooms, 1s. to 1s. 2d. per lb.; Beetroot, 6d. to 7d. per bunch; Brussels Sprouts, 1s. 6d. per stone; Spinach, 2s. do.; Turnip-Swedes, 1s. 2d. per bag; do., Scotch, 2s. 6d. to 3s. per dozen bunches; Celery, Scotch, 1s. per bundle; do., English, 2s. do.; Red Cabbage, 1s. 6d. to 2s. per dozen; Savoy, 1s. to 1s. 3d. per dozen.

LIVERPOOL: December 29.—Average of the prices at under-noted markets:—St. John's: Potatoes, 10d. to 1s. 2d. per peck; Cucumbers, each 10d. to 1s.; Grapes, English, 2s. to 3s. per lb.; do., foreign, 6d. to 8d. do. Pine-apples, English, 4s. to 7s. each; Mushrooms, 1s. 6d. per lb. Birkenhead: Potatoes, 1s. per peck; Grapes, English, 2s. 6d. to 3s. 6d. lb.; ditto, foreign, 6d. to 8d. ditto; Pine-apples, English, 7s. to 10s. each; ditto, foreign, 4s. to 7s. each; Mushrooms, 1s. 6d. to 2s. per lb. North Hay: Potatoes, per cwt., Giants, 3s. 6d. to 3s. 9d.; Main Crop, 3s. 9d. to 4s. 6d.; Bruce, 3s. 8d. to 4s.; Turnips, 6d. to 10d. per dozen bunches; Carrots, 4d. to 6d. per bunch; Onions, English, 3s. 6d. to 4s. 3d. per cwt.; do., foreign, 2s. 6d. to 3s. do.; Parsley, 6d. to 8d. per dozen bunches; Cauliflowers, 1s. to 3s. per dozen; Cabbages, 6d. to 8d. do.; Celery, 6d. to 1s. 4d. do.

CORN.

AVERAGE PRICES of British Corn (per imperial qr.), for the week ending December 25, and for the corresponding period of 1896, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1896.	1897.	Difference.
	s. d.	s. d.	s. d.
Wheat ...	30 9	34 4	+ 3 7
Barley ...	24 1	26 11	+ 2 10
Oats ...	16 1	17 0	+ 0 11

BOOK: W. Y. "Table Decorating." There is no such book published. Miss Annie Hassard's is out of print, and may only be met with at the second-hand book-shops.

CORRECTION.—P. 430, col. a, line 18 from the top, for Chrysanthemum Leonie Service, read Seince.

MULBERRY: Barton. Secure, if possible, straight branches, 1 inch to 2 inches in diameter, and 3 feet to 4 feet in length; cut off the butt end square, and trim off the lateral shoots; then make a hole with a crowbar 1½ to 2 feet deep, in rich soil; drive down the Mulberry stake to that depth. In the first year a few roots and leaves will be emitted.

NAMES OF FRUITS: P. C. P. Apples unknown; seem to be Cider varieties.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—C. W. No. 5, Gleditschia sp. Cannot name other trees from material sent.—C. G. 1, Lonicera brachypoda; 2, Viburnum Tinus var.—H. E. R.—The Cypripedium insignis flower sent certainly is peculiar in the particulars you mention, but it is not a showy form.—E. C. H. P. Yours is the only true pure white form, and it is called Dendrobium Phalaenopsis hololeuca, to distinguish it from the several varieties, with a very slight trace of pink on the lip, which are called "alba" in gardens.—P. C. P. We cannot undertake to name hybrid Veronicas.—E. M. P. The blooms were past recognition; send fresh ones to a Chrysanthemum specialist.

POINSETTIAS: H. J. C. The bracts are fine ones, and, as you imagine is the case, the colour is inclined to crimson rather than to the usual scarlet—a difference doubtless due to something in the soil in which they grow, or to the sort of manure applied.

TOMATOS AND MANURING: Perplexed. Assuming that your land is poor in those ingredients the plant requires, owing to its being repeatedly cropped with Tomato plants, you should apply the following: for every 100 lb. of fruit taken from the soil approximately, nitrate of soda, 14 oz.; dissolved bone black, 5 oz.; muriate of potash, 10 oz.

TOMATOS FOR FRUITING UNDER GLASS FOR MARKET: Perplexed. Chemin Rouge, Duke of York, Ham Green Favourite, Hackwood Park, Young's Eclipse, the last an extraordinary prolific variety.

TULIPS: T. Dodd. The bulbs should have been potted in September and October, and kept cool and in the dark till plenty of roots formed, and some amount of top-growth showed. They can be grown planted thickly in boxes filled with soil, the early single-flowered and early double-flowered being kept separate, and late ones also by themselves. Bottom-heat is a help, but it is not essential. The best you can now do with the bulbs is to plant them in the open, take them up when the foliage turns brown, and make an early start next autumn.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,

MORE THAN DOUBLED, and that it continues to increase weekly.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

THE

Gardeners' Chronicle.

SATURDAY, JANUARY 8, 1898.

OLD ORCHARDS.

OFFICIAL returns give a total exceeding 112,000 acres as devoted to orchards in the counties of Herefordshire, Devonshire, Somersetshire, Gloucestershire, and Worcester-shire, this being considerably more than half the acreage occupied with orchards in the whole of England. At first sight this total looks very encouraging, for all who believe that no better apples are grown than those produced on British soil; but unfortunately it is misleading, and, like many bare official statistics, requires investigation before a correct idea can be formed of the true meaning. A survey of the counties named gives a different aspect to the question, and I have no hesitation in saying that one-half of the acreage recorded is occupied with worthless trees, or with those that are rapidly approaching this condition. This opinion is not the result of a cursory examination, but has been formed after some years of observation and repeated journeys through the chief districts of the five counties mentioned. The subject has been impressed upon my mind most forcibly by recent opportunities for studying the matter, and it seems to me of such importance that I have submitted this brief review of the subject to the Editor of the *Gardeners' Chronicle*, in the hope that he may be able to find space for it in its widely-read pages.

When the general extension of orchard planting in England took place, in the beginning and towards the middle of the seventeenth century, the principal object in view was the production of cider. It is recorded that Lord Audamore, when ambassador in France during the reign of Charles I., obtained from Normandy large numbers of scions of the best cider Apples, which were introduced into Herefordshire and distributed throughout the county.

When Dr. John Beale published his treatise on the Hereford orchards in 1657, he considered them "a pattern for the whole of England," and there is abundant evidence from his and other's writings that in these early days considerable and careful attention was given both to the selection of varieties and to general cultivation. But Herefordshire seems to have been well in advance, though, in later years, both Somersetshire and Devonshire became equally celebrated, and for a period, the last-named county was pre-eminent for its cider production. Certainly, when Hugh Stafford's *Treatise on Cider Making* appeared in 1729 it was an important industry there, and had been so for many years. In the course of the seventeenth century, many writers contributed greatly to the extension of Apple culture, and it must be said that the

methods advocated in the majority of cases were very closely in accord with the best practice of modern times. The varieties were, however, all primarily selected for their qualities as cider-fruits, enormous quantities of this beverage were manufactured, and for a time the best brands are said to have effectually taken the place of the French and German wines amongst the higher classes; while it was also the labourer's constant drink. In the latter case, after a time, fermented malt liquors gradually superseded the lighter cider, and to this end, probably, less careful methods of preparation had contributed. As the cider industry declined, so the interest in the orchards waned; and as large numbers of the trees were of varieties unfitted for other use, the fruit was of little value for sale, and the plantations were simply left to themselves.

What is too painfully evident in the majority of the old orchards at the present time is not the result of ten or twenty years' neglect, it is the effect of a decadence of interest which must in many instances date back to or beyond the beginning of the nineteenth century. It has been variously estimated that an Apple-tree will live to an age of 200 to 1,000 years, but there is little doubt the most profitable period in the life of a standard Apple-tree on the crab stock is from twenty to sixty or eighty years; at least so far as my experience and observation extend where the age of the trees is definitely known, this appears to be the time when the greatest crops are borne, though in regard to healthy trees the period may be prolonged to 100 years or more. This of course is assuming that the best cultivation has been consistently followed throughout, as even with neglect the Apple will "exist" for many years, but only occupying ground uselessly, serving as a harbour for insects innumerable, and the germs of diseases that may infect other trees. A very short time suffices for a tree to get into a bad state by neglect; it is astonishing how quickly the evil is done, and unless very promptly remedied by improved treatment the tree can never become a source of profit. The worst results are occasioned by neglect in the early stages of the tree's existence, because when once thoroughly stunted very little can be done to alter it, and the best treatment seems lost. By far the most serious neglect is in the want of attention to cultivating the soil over the roots and around the trees. The older writers generally agreed in advocating tillage for the soil in orchards, and the general experience of fruit growers is in favour of this at the present time, both here and in America; yet we find nearly the whole of the orchards in the counties named at the beginning of these notes, planted in grass. The chief arguments I have heard in support of this system are poor indeed, and one is in itself a proof of the careless methods adopted in gathering fruit. A farmer who has an extensive orchard of Apples on the borders of Devonshire, the trees in which are more remarkable for their clothing of cryptogamic plants than for their healthy appearance or crops of fruit, says the "Apples don't get mucked up with dirt when knocked or shook off the tree on to grass." The other reason is, that the grass affords a useful grazing-ground for stock. This has some force when the orchard is attached to a cottage or small holding where there is possibly no pasture; but on an ordinary farm, with the usual proportion of feeding-ground, it is not worth consideration in the face of the injury resulting to the trees. That permanent injury does result from growing

trees in grass, unless a space is kept clear round the stems, has been repeatedly proved, the continual competition between the roots of the grass and those of the trees for plant food and moisture in the soil is greatly to the disadvantage of the trees. Close cropping with all its risks of root injury is preferable to this, as can be seen in almost any of the market gardens around London, where fruits are grown in conjunction with vegetables or flowering plants.

Attempts have been made at times on the part of the land-owners or tenants to renovate some of the orchards, but it has generally been done in such an unsystematic or half-hearted manner that little good has resulted. A few old trees have been felled, the roots partly removed from the soil, and the young trees planted in the same places. This in itself is bad enough; but to complete the mischief, the trees have often been left unprotected until seriously barked by hares or cattle, or tied so securely to stakes that in a year or two the bark has been as effectually "ringed" as if that operation had been the object of the planter. When the results have been seen at the end of five or ten years, it has been rightly assumed that money and labour had been thrown away in such "renewals," and so the neglect has gone on again unchecked.

It is a serious matter, for it represents in the five counties alone something like 50,000 acres of good land worth an average rent of at least £1 per acre if well cultivated, and capable of being made to yield at the lowest estimate a total profit of a quarter of a million sterling to the occupiers, which under present conditions is little better than waste land. Nothing but a thorough system of renovation will ever effect any permanent good, and this will necessitate a considerable expense. To restore the majority of existing trees to healthy fruitful condition is almost impossible; the simplest and most satisfactory way would be to destroy them and provide for new plantations. In some cases, the present orchards are in very unsuitable situations, and new sites are desirable; but apart from that, it is preferable in every way where practicable to select fresh ground. If this is not possible, the plan I practise and recommend, where a proportion of the trees afford some fruit, and it not wished to sacrifice the whole at once, is to grub up one half at a time, clear the ground thoroughly of roots, give a heavy dressing of manure, dig or plough it in, and crop with vegetables for a year, then plant with standard and dwarf Apple-trees, and at the end of five years serve the other half in the same way. But in an ordinary way, if the plan is adopted of including dwarf trees on the Paradise with the standards, the whole of a worthless orchard can be treated in this manner at once, as the dwarf trees in a short time will give the supplies needed for present use.

The great question here comes, who is to bear the expense of the work? and this has been the great obstacle to improvement, and is likely to continue so, unless some understanding is effected between landlord and tenant. Where land has depreciated so much in value, and income proportionately decreased, it is scarcely reasonable to expect the owner to bear it all. On the other hand, the tenants regard it as an improvement to the property, in the advantages of which they may have only a temporary share. Perhaps the best way is for the landlord to take the initiative, and endeavour to make an agreement that shall be equally fair

and satisfactory to both sides. This has been done in the following ways, and either of the first two might well be extended: 1st, the landlord finding all the trees, and the tenant undertaking the labour of land-preparation, planting, and subsequent attention; 2nd, the tenant providing both trees and labour, but with an agreement that at the termination of his tenancy he shall receive compensation based on valuation from the incoming tenant or landlord; and 3rd, the tenant supplying trees and labour, but the former retaining his own property, to be disposed of as he may determine, but the land-owner not to be liable for compensation. The last is the least satisfactory, and has in some cases resulted in very harsh proceedings, for if a difference should arise between the landlord and tenant, the latter, unless he holds a lease, may be compelled to quit without realising any return for his labour and expense.

On the other hand, a careless tenant may allow his plantation to become a disgrace and danger to neighbouring orchards. In the other cases the landlord has some control over the cultivation, as it is part of the contract that the trees shall be properly attended to.

Thoughtful men who are interested in horticultural or agricultural questions of the day cannot but recognise that with the enormous demand for Apples there is ample room for increasing our own supplies—but these must consist of good fruit only; and wherever planting is undertaken, proved varieties only should be selected. The poor and damaged fruits being constantly put on the markets from neglected orchards bring down the prices, injure the trade, and convey very erroneous ideas of the returns to be realised from good fruit. *A Planter.*

NEW OR NOTEWORTHY PLANTS.

CYPRIPEDIUM CRAWSHAWÆ, n. sp.

SOME time ago, Messrs. J. Charlesworth & Co., of Heaton, Bradford, received from the Shan States a few plants of a quite new *Cypripedium*, which after the manner peculiar to many good things, did not readily bear travel. The plant which I have seen somewhat resembles *C. Parishii* in growth, but the leaf and size of the plant are more those of *C. Charlesworthii*. The leaves are, however, much more fleshy than those of that species, and bright green above, and entirely greyish-green beneath, the plant in no part exhibiting the purple markings usually seen on *C. Charlesworthii*. The collector's letter and a fine dried flower have now been forwarded. The collector says: "It is an entirely new *Cypripedium*. The flower-stalk is pale green and hairy; the flower is shaped like *Cypripedium Charlesworthii*, but it is larger, and the purple markings are entirely absent. In this the upper sepal is pure white, with a pale greenish blotch at the base, and a very slight tinge of the same colour at the tip. The petals, lip, and lower sepal are entirely of a pale greenish-yellow colour—my natives describe this as "wa-pyan-byan"—a soft yellow. The whole flower is very glossy, and I consider it a much finer thing than *C. Charlesworthii*." The dried flower sent seems to bear out the collector's statement exactly. It may roughly be described as resembling *C. insigne Sanderæ* in colour, but with more of the form of *C. Charlesworthii*. In size, however, it is superior to both. Mr. Charlesworth wishes it to be dedicated to his sister. *James O'Brien.*

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM INSLEYI.

THIS plant greatly resembles *O. grande* in its pseudo-bulbs and foliage, the leaves being longer. The scape rises from the base of the leaves, and is

erect. A plant now in flower, at the Botanic Garden, Edinburgh, is carrying fourteen flowers, the sepals and petals being pale yellow in colour, with chestnut-brown blotches and markings the lip of a bright yellow, with reddish spots, while the column bears the distinguishing pair of horns of reddish-chocolate colour. It enjoys a position at the cool end of the Cattleya-house, and, flowering late in the season, is decidedly attractive. Several varieties of this species are in cultivation distinct from the type in their broader sepals and petals, or in their colour, the best known of which is perhaps *O. Insleyi splendens*. It is a native of Mexico, and was first introduced by Mr. Barker in 1839. *R. L. H.*

LÆLIA ALBIDA.

This pretty winter-flowering Orchid seems to have been flowering with exceptional beauty this season, if we may judge by the fine examples sent by various correspondents. From Joseph Broome, Esq., of Llandudno, comes a grand inflorescence, the flowers of which were unusually large, the sepals and petals cream-white, the apex of the lip light rose, central keels orange colour. From Walter C. Walker, Esq., Winchmore Hill, the fine *L. a.* var. *Stobartiana*, with the sepals and petals tipped with rose-purple; and *L. a.* var. *Walkeri*, a still finer flower in the same way. Another fine form, with rose-tinted sepals and petals, is sent by Mr. M. J. Watts of Clifton. *L. albida* is a very floriferous plant, and with proper management it may be grown in an ordinary greenhouse or conservatory.

THE ROSARY.

CLOTH OF GOLD ROSE.

"WILD ROSE" did well, in a recent issue, to call attention to this hitherto unexplained mystery once more. Before the advent of Rose *Maréchal Niel*, Cloth of Gold was comparatively common. I made many pilgrimages to see notable specimens in East Anglia, huge specimens, many of them covering gable-ends and sides of mansions, and other bare spaces. The variety was also met with at times in the open, as large bushes. Occasionally, too, it was allowed to climb up the stems of trees, or to form tangled thickets in warm nooks in woods. But whether as cause and effect, or by a mere coincidence, scarcely had the *Maréchal Niel* made his *début* in our gardens, than the planting of Cloth of Gold became less frequent, and now this Rose seems to be in danger of extinction. Certain it is that the climate of this country is unchanged, whilst all this curious and mysterious change was taking place, and our admiration for golden Roses has not become less ardent, but the one has paled before the rising popularity of the other. And the probability is, that where the Cloth of Gold grew and bloomed in years long ago it would do equally well to-day.

The old veteran Cloth of Gold Roses perished often through reckless slaughter, as pointed out by "Wild Rose," or through inadvertent cutting-back, severe pruning, or frost injury. Possibly your correspondent was in error in describing a Cloth of Gold Rose with a stem 15 inches in diameter. [Circumference was intended. Ed.] But a point should be made of the size and age of the Cloth of Gold or other golden or other Rose, as showing their capabilities of withstanding severe weather for many years. It is largely true that the bigger, the older a Rose-tree, and the hardier, and also the more floriferous. Hence, in many cases, no sooner was the veteran Cloth of Gold cut down, by design or accident, than then its glory departed, either by slow degrees or suddenly. The concentration of vital force into the few new growths sent the Rose shoots off into fishing-rod lengths, sappy, and full of pith, and these ripening imperfectly would easily be injured by frost.

The stupid practice of cutting back old Tea or Noisette Roses almost to the ground-line is responsible for the loss of many a venerable plant; and even when that does not immediately follow, the plants are shorn of their beauty. On the heels of such a practice follows a struggle for life, rather than a revival of health; and the younger and smaller shoots being more tender than the ancient stems that

were cut away, hence a general decline in vigour sets in. This useless destruction of the aged Roses left the more tender parts of the plants several feet nearer to the ground, thus probably reducing them to more degrees of cold than prevails 10 to 20 feet higher. Hence, after severe pruning, natural or artificial, it takes some of the tenderer Roses years to regain their normal degree of hardiness. This fact is evident by the losses among *Maréchal Niel* as well as Cloth of Gold and other Roses. The effect, too, of altitude on the hardiness of Roses has not received the attention it deserves, for thousands of plants *Maréchal Niel* have been killed to the ground line while tall standards, and those worked high on Dog roses, The Glory, Banksian, or climbing Roses on high walls or up trees, have escaped unhurt. *D. T. F.*

SEDUM SEMPERVIVUM.

THIS new introduction from Asia Minor, found by Mr. Siehe of Mersina, is a pretty *Sempervivum*-like *Sedum* possessing cochineal red flowers, which are produced in great abundance, see fig. 7, p. 19, which shows the plant of its natural size. It is a plant well adapted for carpet-bedding, and everyone who has seen it is surprised at the beauty of the plant. *U. Dammer.* [This can hardly be called new. It is described at length by the Editor in our volume for December 14, 1878, p. 750.]

NOVELTIES OF 1897.

(Continued from p. 2.)

MESSRS. F. SANDER & Co., St. Albans, out of their importations have flowered *Eriopsis Helenæ*, a pretty species with yellow and purple flowers; *Luddemannia Sanderiana*, a very distinct novelty; *Maxillaria elegantula*, yellow and purple; *M. dichroma*; the singular looking *Lycaste Mooreana*, and the fine *L. Skinneri pulcherrima*, and *L. S. rubella*; also *Leptotes nana*, the singular white *Dendrobium Gratrixianum*, and the floriferous *D. Bancroftianum*, said by some to be a form of *D. speciosum*, but quite a slender plant. Of fine varieties of showy species, Messrs. Sander flowered *Cattleya Mendeli fimbriata*, *C. Shroderæ* "Queen Empress," *C. Mossiæ* "Empress of India," and *C. M. rubens*. Of their hybrids, the best are *Cattleya* × *Dominiana* "Empress," and *L.-C.* × "Our Queen," shown at the Royal Horticultural Society on June 15; and among their introductions to the *Cypripediums* are *C.* × *Mrs. D. Solomon* (*Lathamianum aureum* × *Spicerianum*); *C.* × *Mrs. E. Uihlein* (*villosum aureum* × *Leeanum giganteum*); *C.* × *conco-villosum*, *C.* × *Oakes Ames* (*Rothschildianum* × *ciliolare*), *C.* × *Clement Moore* (*Dauthieri* × *Leeanum*), *C.* × *Rodolfiana* (*Harrisianum* × *insigne Sanderæ*), and a number of others. Also in Messrs. Sander's list for the year are *Lælio-Cattleya* × "Fire Queen," *Odontoglossum grande* var. *Pittianum*, *Phaio-Calanthe* × *Brandtiæ*, *Sobralia Holfordi*, *Lælio-Cattleya* × *amoena*, *Gongora Sanderiana*, *Zygopetalum venustum*, *Warrea grandiflora*, &c.

Messrs. Hugh Low & Co., Clapton, have been specially fortunate in flowering good novelties during the past year, the best of theirs being *Odontoglossum* × *excellens Lowiæ*, and *O. crispum* "Queen Victoria," two grand varieties. *Cattleya Mossiæ*, "In Memoriam Richard Curnow," perhaps the largest and best *C. Mossiæ* of the year; *C. Hardyana*, Low's variety, very richly coloured; *Cypripedium* × *Mrs. E. V. Low*, a chaste novelty; *Lælia pumila*, Low's variety, lavender-blue tinted; and *Calanthe Veitchi alba*.

Messrs. W. L. Lewis & Co., Southgate, have made a specially good mark this year through the number of grand varieties which have flowered out of their superb strain of

Laelia pumila, stands of which, with distinguished fine varieties, having been shown by them on several occasions. The best large coloured varieties are their *L. pumila magnifica* and the *L. p. superba*, shown by R. W. Richards, Esq., of Usk, at the last meeting of the Royal Horticultural Society; the most remarkable was the blue-tinted *L. p. Gatton Park* variety, for which Jeremiah Colman, Esq., secured a First-class Certificate; and some pretty white, or nearly white, forms

being of a yellow instead of a greenish hue; and *Cattleya labiata* Emperor, a gigantic and finely-coloured variety. Of his hybrids *Laelio-Cattleya* × *Cypheri* (*purpurata* × *Forbesii*) is his prettiest novelty of the year. Mr. Jas. Douglas, of Great Bookham, at the meeting of the Royal Horticultural Society, December 14, showed the pale yellow *Laelia* × *Briseis* (*harpophylla* × *purpurata*).

Mr. Thos. Rochford, of Turnford Hall Nursery, from whose great stores of Orchids grown

pilia brevis, shown by Sir Frederick Wigan; *Cypripedium* × *Lilian Greenwood*, and the *C. × bellatulo-vexillarium* of Mrs. Briggs-Bury; *C. × Leeaenum magnificum* of Mr. G. Shorland Ball; *C. × callo-Rothschildianum*, of J. Gurney Fowler, Esq.; *Laelia pumila*, Gatton Park variety, of Jeremiah Colman, Esq.; and *L. p. superba*, of R. W. Richards, Esq.; *Laelia* × *Hippolyta*, *Dulcote* var., and *Zygopetalum Jorisianum*, of Walter Cobb, Esq.; *Dendrobium nobile*, Hutchinson's var., of General Hutchinson; *Odontoglossum Pescatorei*, *Sligachan* var., of J. Wilson Potter, Esq.; *O. × excellens* "Richard Ashworth," *O. × Andersonianum*, *Danehurst* var.; the singular natural hybrid *Vanda* × *Moorei*, of Mr. Moore, of Bradford; and, among other fine varieties, the *Odontoglossum crispum aureo-marginatum*, of Messrs. B. S. Williams & Son.

Continental Novelties have been fairly represented by fine exhibits of Messrs. Linden of Brussels at the Royal Horticultural Society. Of these the phenomenal *Odontoglossums*, for which the firm is noted, gave the wonderful *O. crispum Luciani*, said to have been sold for 12,000 francs (£480), the highest price ever fetched by an *Odontoglossum*; *O. crispum Kegeljani*, and *O. c. Ami Charles*, both very fine; and *O. Pescatorei Imperati*, richly spotted with purple. Their grand strain of *Cattleya Trianæi* has yielded many fine novelties, of which the two finest are *C. T. Imperator* and *C. T. eximia*, though those named *Lindenianæ*, *illustris*, *dilecta*, *princeps*, and *Miss Linden*, are likewise grand flowers. Their *Vanda* × *amœna* is a pretty natural hybrid of *V. cœrulea*; *Cattleya Mossiæ*, *Queen Empress*, and *C. M. Moortebeekiensis*, two splendid things; and *Cypripedium* × *Lebaudy-anum*, and *C. × Beekmanii*, two fine acquisitions.

M. Chas. Maron, Orchid-grower to M. Fournier of Marseilles, a great raiser of hybrids, announces among others, *Cattleya* × *Astrea* (*Skinneri* × *Loddigesii*), *C. × Fernand Denis* (*Acklandiæ* × *Warszewiczii*), *C. × Feutillati* (*Leopoldi* × *superba*), *C. × Bréauteana* (*Loddigesii* × *superba*), *C. × Gaudi* (*Leopoldi* × *Loddigesii*), *C. × dubia*, of doubtful parentage; and several new forms of *Laelio-Cattleya* × *Canhamiana* and *L.-C. × callistoglossa*, obtained by selection of the parents used.

M. A. Peeters, St. Gilles, Brussels, flowered many good things, among the best being the *Odontoglossum crispum Peetersii*, a handsomely blotched variety; *O. c. Mrs. Peeters*, a charming novelty, with distinct red-brown blotches and pretty flush of rose; *Miltonia vexillaria Hyeana*, and *M. v. virginialis*, all shown at the last Temple Show.

New or rare Orchids illustrated in the *Gardeners' Chronicle* in 1897 are:—

Bulbophyllum Ericssonii, January 23, p. 61.

Bulbophyllum Medusæ, January 9, p. 25.

Cattleya × *Empress Frederick* var. *Leonata*, December 18, p. 429.

Cattleya Mossiæ *Queen-Empress*, June 12, p. 379.

Cattleya Mossiæ *Rappartiana*, July 10, Supplement.

Cattleya Schofieldiana gigantea, October 9, Supplement.

Cattleya Warszewiczii "Mrs. E. Ashworth," September 4, p. 163.

Coryanthes Fieldingi, July 17, pp. 31, 33, 39.

Cypripedium × *Chapmanni magnificum*, June 5, p. 365.

Cypripedium Lawrenceanum Hyeaenum (Cookson's variety), January 16, p. 37.

Dendrobium × *Kenneth*, February 27, p. 135.

Dendrobium Victoria Regina, August 21, p. 121.

Epi-cattleya × *Matutina*, April 10, p. 233.

Epi-laelia × *radico-purpurata*, August 7, p. 83.

FIG. 7.—SEDUM SEMPERVIVUM: FLOWERS REDDISH-CRIMSON. (SEE P. 18.)

have also appeared. Messrs. Lewis & Co. are credited with the delicately-tinted *Cattleya Mendeli* *Madonna*, and the pure white petalled *C. labiata* *Lewisii*. Mr. James Cypher, of Cheltenham, famed for the high culture of his plants, received recognition at the Manchester Great Show for *Laelia purpurata* *Thompsoni*, *L. p. Schofieldiana*, and *Cattleya Mendeli grandiflora*, all fine examples of favourite species; and at the November Show for *Cypripedium insigne*, var. *Dorothy*, a fine yellow form; *C. × Leeaenum aureum*, var. *giganteum*, differing only from the original *giganteum* in

for market purposes many fine things may be expected, flowered the charming *Vanda cœrulea* *Rochfordiana*, a pure white variety, with pale pink labellum; the first wholly white *Dendrobium nobile*, *D. n. virginale*, and some good white and blush-white varieties of *Laelia pumila*.

Of other good things certificated and shown, mention must be made of *Laelia* × *Lucy Ingram* (*purpurata* × *Perrini*), and *Laelio-Cattleya* × *Venus* (*L.-C. × elegans* × *C. Percivaliana*), raised by Mr. C. L. N. Ingram; the fine *Laelio-Cattleya* × *Lady Wigan*, of Messrs. J. Charlesworth & Co.; *Tricho-*

MARKET GARDENING.

WHERE AND HOW TO START A MARKET-GARDEN.

THE market-garden industry has attained to enormous dimensions and importance during the last ten or twelve years. This is not to be wondered at, seeing that the cultural skill, energy, and business of the market-gardener are exclusively directed to the task of growing produce in sufficient quantity to meet the growing demand of the ever-increasing millions living in our cities and towns for wholesome food in the way of choice and ordinary vegetables, both in and out of season. Indeed, so largely has the demand been annually increasing in this direction, that the area of land under vegetables, such as Asparagus, French and Runner Beans, Beetroot, Brussels Sprouts, Cabbages, Celery, Cauliflowers, Cucumbers and Tomatos, Lettuces, Peas, Rhubarb, Seakale, Spinach, and other things, including fruit and popular flowers, exceeds 100,000 acres. As a large percentage of the readers of the *Gardeners' Chronicle* consist of the market-garden fraternity, who, like horticulturists generally, refer to its pages weekly for practical and helpful information, and seeing that the ranks of market-gardeners are recruited from the rank and file of gardeners, it will not be out of place here to insert a few general remarks, for the benefit of those who may be about to commence business as market-gardeners.

The following are points that should be carefully considered before the field of one's operations is fixed upon, and a considerable sum of money risked—perhaps a life's savings in the venture:—1, proximity of the spot to a railway-station, and towns in which the productions raised can be sold; 2, texture, depth, and fertility of soil; 3, water-supply; 4, situation and aspect of the land as regards exposure to the south and west, and protection from the north and east winds, and evenness of surface of such portions upon which it may be the gardener's intention to erect span-roofed glasshouses, and which should run north and south. Should the ground rise two or three feet in 100 or 150 feet in this direction, it does not matter in the least so long as it is level, or nearly so in the opposite direction—otherwise, heavy expenses will have to be incurred in removing and levelling soil. Particular attention for such site should be paid to the underground water-level; inattention to this point may result in the submergence of the floors, stokeholes, &c., at any time. (6) The adaptability of those about to embark in the business of a market-gardener for the work; and (7) bearing in mind in selecting a favourable spot in which to commence, that the nearer the scene of the market-gardener's operations is to the outer circle of the smoke-laden atmosphere of large and populous towns the less money will be swallowed up by the carriage of goods. In support of the assertion that market gardening is a paying industry, we need only refer to the fact that land in the vicinity of large and populous towns is always devoted to raising crops of vegetables, thus proving conclusively that the land is considered much too valuable by the owners to be

cropped with cereals or roots. Moreover, there is abundance of evidence of the truth of the old law "Small beginnings often grow into big endings," as many of the larger market-gardeners of the present day began in a small way with, in some cases, only their own pair of hands to do the work, and by well-applied skill, industry, and perseverance, and sound judgment in considering the requirements of their local public, and the public demands generally, have gradually, and, in some cases rapidly, succeeded in building up and extending their respective businesses to large dimensions—a circumstance which goes to show what may be accomplished with a moderate amount of capital, and well-directed skill, industry, and energy.

Those who intend entering upon the business of a market-gardener should select land close to the outskirts of a large business town in which there are but few market-gardens established. In the matter of glasshouses, low, narrow, span-roofed ones with sunken paths are to be preferred, and these should be efficiently heated with hot-water pipes for forcing Asparagus, Seakale, Chicory, French Beans, Rhubarb, Radishes, Cucumbers, Tomatos, as well as foliage and flowering plants, including Hyacinths, Narcissus, and other bulbous plants. These, when well grown and sent to market at the right time, realise remunerative prices. In connection with the sum total thus turned over, the cost of production, such as the cost of coal and coke delivered, and the securing of a good supply of water, must not be overlooked when selecting land.

Before proceeding to erect glasshouses, their number and character, and the purposes they will serve, must be well thought over, and a plan of the ground and the intended glasshouses should be prepared, this plan being adhered to, even should all the houses not be erected at one time. If two or more houses be required for early, mid-season, or late Grapes, for Melons, Cucumbers, Peaches, Tomatos, or any other plant requiring the same temperature, the only walls that need be built, whether five or 100, are the two outside ones, in addition to the end walls. Brick piers, of 9 inches square, built on concrete footings, at about 7 feet apart, for supporting planks of pitch pine, on which the wall or gutter-plates for supporting the rafters are nailed, will afford complete stability to the block of houses thus built. The wood employed in the construction of such glasshouses should consist of best well-seasoned yellow deal, excepting the valley-plates, which, as already stated, should be pitch pine, this being 12 inches by 1½ inch, and tarred on both sides. The other items of wood necessary to the erection of houses of the description mentioned above, are as follows:—Wall and end-plates, 3 inches by 4 inches; end-rafters, 3 inches by 4 inches; bars or intermediate rafters, 1½ inch by 3 inches; end and division-bars, 1½ inch by 3 inches; ridge, 1½ inch by 6 inches; capping, 1 inch by 4 inches; drip, 1 inch by 3 inches; door-frames 3 inches by 4 inches, with oaken cills of the same size; doors, 6 feet 6 inches by 2 feet 8 inches, the doors being either all wood, or they may be made of one half glass; and if purlines are deemed necessary, they should be 2½ inches by 3½ inches, bevelled, the vertical supports being 2 inches by 3 inches. If the brickwork (walls) are from 2½ feet to 3 feet high from the ground-line of house, and the latter is 12 feet wide, 8-feet rafters will afford ample space and angle for Cucumbers and Melons. For Grapes, Peaches, Tomatos, and Figs, houses 25 feet wide, with 14-feet or 15-feet rafters, will be suitable in every way. Purlines should be used in this class of house, and iron side-ties should be employed in all the houses. These, consisting of ¾ inch by 1 inch bar iron, and about 4 feet long between the two cranks, should be secured to the wall-plate with coach-bolts at intervals of about 15 feet, the bottom-end being let into the border in holes sufficiently deep to take a good-sized bucket of concrete, consisting of two of finely-broken bricks to one of cement in each. The necessary number of roof ventilators should be worked throughout with Harris's or similar gear; the woodwork should receive two coats of paint before being fixed, and

one more afterwards. The glazing may be done with glass 21 oz. to the foot, this being bedded in the best white-lead putty, and sprigged on the top, putting four brass spriggs to each square of glass. Of course, the several glass structures should be efficiently heated with hot-water, using 4-inch pipes for the purpose. Readers who may contemplate going in at once for market-gardening on the lines I have set forth, should lose no time in placing their orders in the hands of a builder having a good reputation for erecting glasshouses of the kind indicated, who would probably be in a position to erect from half-a-dozen to fifty houses of the dimensions given above, and 200 feet long each, within a month or six weeks from the time of receiving the order; the hot-water engineers following closely on the heels of the painters and glaziers. *H. W. Ward, Rayleigh.*

MARKET CHRYSANTHEMUMS.

The season just past has been far from a happy one for Chrysanthemum growers. Although the quality of bloom has perhaps never been higher, prices have never been so low, and that the mild weather has been largely responsible for this is amply evidenced by the fact that salesmen in even some of the most northern centres have declined to receive supplies on the ground that such a quantity of "outdoor stuff" was coming in. Indeed, the mere fact that whilst but indifferent blooms last year fetched 4s. 6d. to 6s. per dozen bunches, specimen blooms have this autumn frequently realised only one half those prices, is sufficient to prove that it is not growers who have been wholly at fault.

Nevertheless, there are lessons to be learned from this season's disappointments, which Chrysanthemum growers should take seriously to heart before preparing for their next campaign, and of these perhaps the most important is that, if the mild season has been the main factor in recent disastrous results, the extensive—and apparently still extending—production of early varieties has had much to do with bad prices. Those growers—and, unfortunately, they are in the majority—who pinned their faith on such sorts as *Selborne* and *Source d'Or*, probably, as offering a crop which could be got in without the use of fire-heat, have been the greatest sufferers from the general glut in the markets. As a proof of this, one has only to remember that whilst fine *Selbornes* were sold with difficulty at a few pence per dozen blooms, and smaller ones were practically unsaleable at any price, late November and December whites of not nearly such good quality, in some instances sold readily at treble the price just indicated. The "average grower" of Chrysanthemums, as of everything else for market, is he who clings to old systems, and it cannot be expected that he will alter his methods entirely even after the sharp teaching of this season. Still, it is obvious that it is the up-to-date grower who spreads his supplies over all the period available who has reaped the most satisfactory reward for his labours. It may be argued that the more growers produced later blooms, the lower the price would be; but what we want to guard against is a universal output of a thing at a given time, and a glut later in the season can never be so keenly felt as it is in October, when the weather is usually fairly mild, because prices could not, at any rate, be influenced by any heavy arrivals of outdoor blooms, other blooms as well as those of Chrysanthemums, be it remembered, helping the competition when the early-flowering varieties are placed on the market.

Again, if the average grower of the Chrysanthemum suffers, and makes others suffer, by his extravagant output of early varieties, he sins also in the monotony of the varieties chosen. Going the round of the florists' shops in October, what do we find in every one? Nothing whatever but one dull routine of *Selborne* and *Source d'Or*, with here and there perhaps *La Triomphante*. That every grower turns out the same stuff, and that every shop-keeper but repeats his neighbour's display, is astonishing in itself; but it is the more amazing when proofs are not wanting that the public is heartily sick of the system. It is part of this class of growers' method to hold his hand after his heavy output of these two varieties for a

necessarily smaller output of "Christmas stuff;" but here again we find the same monotony, only now, instead of the sameness of white and bronze, it is the sameness of white and yellow—Lady Lawrence, L. Canning, and W. H. Lincoln.

It is generally admitted that Selborne is the best white at its own particular season, and Canning is equally indispensable, not because it is very good, but because there is nothing to replace it at all. The industry of raisers of new kinds is so devoted to the introduction of those which will bring them fame at the November shows, that the needs of the grower for the Christmas and New Year's markets have been practically overlooked, and there still awaits plenty of money for the man who can introduce a really reliable late white—one more certain than Princess Victoria, which often comes a washy pink or dirty yellow, of better build than Canning, and dwarfier than Lady Lawrence. But for variety in coloured sorts, either early or late, we are not so handicapped.

financial result to that from growing Source d'Or and Lincoln.

The newer varieties of any market stuff are often objected to on the ground that their initial cost is too great. The grower reflects that he has plenty of his own cuttings of Selborne, Canning, Source d'Or, and Lincoln; that the blooms "fetch something," and he asks why should he go to the expense of buying fresh stock? It is a short-sighted policy. Take Source d'Or, for instance: to realise a really good price, a plant of this variety could not carry more than six or eight blooms; it requires a lot of feeding even to obtain these of requisite quality, and throughout its season of growth it wants continual tying. Now, compare this with one of the newer sorts just named. This will perfect twelve to eighteen blooms, each of which will sell for much more than the best bloom of Source d'Or; it requires next to no feeding, and a couple of ties keep its stiff, dwarf stems up until it is ready for housing. It is

of large lanceolate bright-green fronds, which are sometimes 4 feet or more long, and a foot wide. According to J. Smith (*Ferns, British and Foreign*), it sometimes grows even larger than this, a correspondent in Penang having told him of two fine specimens, each with from forty to fifty perfect leaves, the average length of which was 6 feet, and from 12 to 14 inches wide, and looking in the distance not unlike American Aloes.

The species is widely distributed in the Old World tropics, and several varieties of it are known, all, however, with entire fronds. A new variety, remarkable for the division of the upper part of the fronds into numerous lobes, some of them a foot long and lobed again, has lately been added to the Kew collection through the kindness of Mr. F. M. Bailey, F.L.S., Colonial Botanist, Brisbane, who communicated the following information, together with the photograph which is here reproduced (fig. 8), to the Director at Kew:—"While at the north

FIG. 8.—CRESTED BIRD'S-NEST FERN; ASPLENIUM NIDUS VAR. MULTILOBATUM.

Here among the newer sorts we shall find as many shades and shapes, even of the favourite bronze and yellow, as will satisfy the most ardent seeker for change. No grower could be expected to grow new sorts because they are new; there are plenty of sorts which wise men have "let others try," and of these one can easily name a few which, in American parlance, have "come to stay." For example, there is a magnificent variety of M. Calvat's recent introduction which unfortunately bears the name of an old unsatisfactory sort, Boule d'Or. This is catalogued as "rather early;" but, as a matter of fact, its grand incurving blooms can be had good at Christmas. They have been very fine this Christmas. This variety may be cited as what a really good market plant should be; it has good blooms, it resists mildew, and its strong stiff stems require little tying. Then there are La Mouchetotte, good till February; Le Rhone, Australian Gold, Modestum, New Phoebe, Sunstone, Lady Hanham, and many others. But two or three of these sorts only would soon show a different

unlikely that Chrysanthemum blooms, however well finished, will ever fetch the high prices they used to do; therefore, it behoves growers to produce them at the lowest possible expense, and a way is certainly open to do this by studiously selecting the newer sorts, which, naturally large-flowered, and dwarf, and sturdy, quickly save twenty times any extra cost incurred in the purchase of fresh stock by the saving of labour in tying and feeding, not to mention the advantage of better blooms at the end of the grower's ten months' toil and anxiety. A. C. Jones, Thornhill, Rutterne, near Southampton.

CRESTED BIRD'S-NEST FERN (ASPLENIUM NIDUS VAR. MULTILOBATUM, F. M. Bailey).

TYPICAL A. nidus is a well-known Fern in gardens, large specimens of it being not uncommon. It forms a dense mass of moss-like roots, and ultimately a short, thick stem supporting a vase-like arrangement

recently, I found that Mr. C. J. Nugent, who has collected many plant specimens for me, had brought from the top of the Trinity Bay Range a very beautiful and remarkable specimen of Asplenium nidus. This I arranged with him for, and have much pleasure in forwarding it to you in a Wardian-case. . . . I have an idea that spores taken from the multilobed fronds might have a tendency to form similar plants to the parent, for the spores of Ferns, being asexual, in some respects approach to gemmæ or bulbils, and they may reproduce plants similar to those from which they were taken. I will call this variety multilobatum."

Spores have already been sown at Kew; and as spores of the type vegetate readily, a batch of young plants having recently been raised, we shall probably soon have a big stock of the new variety, which is in many ways a most remarkable Fern.

A. nidus is one of the few Ferns that have been figured in the *Botanical Magazine* (see t. 3101, 1831). It is there described as a parasite on the trunks of

trees. The mode of growth of this plant, its fronds forming a circle, hollow in the middle, would alone justify the specific name given by Linnaeus; but it seems to have arisen from another circumstance. "The root," he says, "fixes itself upon the lofty trees, whence the leaves rise erect, and arrange themselves in a circle, like an umbel, in the hollow centre of which the birds are frequently accustomed to build their nests." Mr. Hart, Superintendent of the Botanical Department, Trinidad, has lately sent to Kew a photograph of the variety known as *muscifolium*, in which the plant is shown to be about 9 feet in diameter, and to have about fifty fronds, each 6 feet by 1 foot. Mr. Hart says it has stood in the same position in the same tub for over eleven years. *W. W.*

PLANT NOTES.

GARDENIA DEVONIANA.

THIS species is remarkable on account of its long trumpet-shaped flowers, which appearing during the winter months, make the plant valuable for the decoration of our stoves. It has a shrubby, compact habit, and grows to a considerable size, and is evergreen. The branching is dichotomous, while the dark green leaves are clustered near the apex of the shoots. In manner of flowering the plant resembles *Randia maculata* (*Gardenia Stanleyana*), figured from this garden in *Gardeners' Chronicle* of October 3, 1896. Like that one, the flowers are terminal and solitary, but they change from white to a creamy colour a short time after expanding. They are 9 or more inches long, and if the plant is well flowered it certainly presents an uncommon appearance. Being a native of Sierra Leone, a tropical temperature is required. It is figured in the *Bot. Reg.*, vol. xxxii., t. 63, and is named in compliment to the Duke of Devonshire, being collected by Mr. Whitfield, the collector of so many fine flowering plants of that district. *R. L. H., Royal Botanic Gardens, Edinburgh.*

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Platylinis (Dendrochilum) glumacea, &c.—Any plants which are showing young growths may be removed to the coolest part of the East Indian-house, and in order to produce strong flowering breaks, the plants should be raised to the roof, in a very light position short of actual sunshine, and when the growths are grown to about two inches in height, they commence to emit roots, and this is the best time to repot it if repotting should be required; otherwise the plant should wait till the flowers fade. A compost consisting of good fibrous peat and sphagnum moss, intermixed with a moderate quantity of clean crocks suits the plant. Till growth is completed the plant should be afforded plenty of moisture at the root; and on bright days the under sides of the leaves should be syringed in order to keep red spider in check. *P. filiformis* and *P. uncata*, although quite distinct, require nearly the same kind of treatment; and all three species deserve to be more commonly grown. As table plants, and especially where tall vases are used, their pendulous, slender, racemes make them pretty objects. *P. uncata*, now flowering abundantly from its half-grown breaks, will require abundance of water. It thrives luxuriantly if suspended in a light part of the intermediate-house the year round; and *P. filiformis* flourishes under the same conditions. This plant has just completed its growth, and will consequently require less water at the root; but although it is at rest the compost should be kept slightly moist—and in order to avoid saturating the materials, my practice is to take the plant down two or three times a week and, according to the state of the weather, give it a thorough syringing overhead, and by this means keep the pseudo-bulbs plump, and the leaves fresh-coloured. *P. Cobbiana* is another pretty species that has just gone out of bloom, and will require to be well supplied with water till growth is fully made up, after which the treatment afforded to *P. filiformis* will suit it.

Sobralia macrantha, *S. Warscewiczii*, *S. virginalis*, *S. albo-violacea*, *S. leucoxantha*, and some others

are making growth fast, and in order to afford the new stems space, those which have flowered should be cut off at the ground-level, and the growths staked out clear of each other. All species of *Sobralia* succeed under intermediate-house conditions the whole year. The plants will not require nearly so much water at the root now as during the heat of summer, too much water at this time of year being likely to cause the leaves to become spotted, and their points to turn brown.

The Cattleya-house.—Plants of *Cattleya labiata* Warneri, with growths now starting, should be raised to an airy part of the roof at the warmer end of the East Indian-house, keeping them there till growth is finished, then returning them to the Cattleya-house to flower. While growth is being made, the plants should be carefully afforded water, the compost being kept moist only. The proper time to repot the plant is as soon as the flowers fade.

Dendrobium Clio ×, *D. Burfordiense* ×, *D. Wardianum*, *D. micans* ×, *D. Juno* ×, *D. Wiganæ* ×, and *D. Wardiano-japonicum* already starting into growth should be afforded water at long intervals of time, and not subjected to a high temperature, or the breaks that are showing at the base of the pseudo-bulbs will grow too rapidly and prevent the flower-buds coming to perfection. These growths will remain almost stationary for a long time if the plants are kept in the resting-house. When the flower-buds begin to open, the plants should be removed to a light position in the Cattleya-house. *Dendrobiums* that do not generally start into growth when their flower-buds show, namely, *nobile*, *aureum*, *moniliforme*, *tortile*, *Ainsworthii* ×, *splendidissimum* ×, *Dominianum* ×, *endocharis* ×, *Virginæ* ×, *Leechianum*, &c., may be brought from their resting-house into a somewhat warmer one, the intermediate-house being a suitable one for a week or two, after which they should be put into the East Indian-house in a light part. These plants require at this season but little water at the root, just as much as will keep the pseudo-bulbs from shrivelling, and favour the slow advance of the buds. The species *D. Parishii*, *D. albo-sanguineum*, *D. crepidatum*, *D. cretaceum*, *D. transparens*, *D. Pierardi*, *D. primulinum*, &c. are still at rest, and should be kept rather dry till the flower-buds show, when some degree of moisture and more warmth are required. *Dendrobium Cambridgeanum* is now starting to grow, and should be removed to the cool-house, where it should remain till the growths show for flower, when the plant may be gradually inured to the East Indian-house conditions. Plenty of water should be afforded after the breaks have started to grow.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Shady places under Trees.—The sides of shady walks and the ground underneath large-headed trees, where most kinds of shrubs fail to do well, can be beautified by planting Ferns, *Periwinkles*, *Primroses*, bulbs of *Crocus*, *Snowdrop*, *Daffodil*, *Scilla*, *Winter Aconite* and *Chionodoxa*, increasing the area planted gradually year by year. Growing as the bulbs do at different periods of the spring, these often otherwise neglected and uninteresting portions of the garden, can at a very small expense, and with little trouble, be rendered very attractive, and once they are planted needing but little further attention.

Primrose roots gathered from the woods and downs, if planted on the edges of shrubberies, in any available nooks and dells, will help to brighten and enliven the garden in early spring.

Summer Bedding Requirements.—All arrangements as to the number of plants required to be raised from cuttings and seeds for summer bedding, should be forthwith decided upon. Where large quantities of *Alternantheras* are required in carpet beds, propagation should now be commenced. Let the cuttings be inserted in 48's, filled with sandy soil. Place these in a brisk bottom-heat in a hot-bed frame, or the propagating-house.

Cannas.—Seeds of those which are to be made use of in the beds should be sown without delay in pans or pots plunged to the rims in strong heat. The seed being very hard, germination will be helped if the seeds are soaked in luke-warm water for some hours before sowing them. Some of the plants will be some weeks longer than others in coming up, and the best way, or at least the safest, is to count the seeds sown in each pot or pan, and lift those which come up when ready for potting-off out of the seed-pan with the point of a label, taking care not to disturb

the ungerminated seeds, and retain the seed-pan in the hot-bed till the other seeds are germinated.

Hollyhock-seed if sown at this date will produce plants that will flower during the first summer. Let plenty of sand be used in the soil with which the seeds-pots are filled, and place these in a mild hot-bed or warm-house, potting off the seedlings as soon as they are large enough to handle into small pots. Afford water very carefully to the seed-pots, the seedlings being very liable to damp off. Continue to repot the plants as fast as they fill the soil with roots, decreasing the temperature as the spring advances, and hardening them off properly before planting them out. If the plants are in 48's or 32's when planting-out time arrives, the more satisfactorily will they flower. The end of April or the beginning of May form a suitable time for planting seedlings, the gardener being, however, guided by the sort of weather prevailing. The soil for the Hollyhock should be rich, and the stations deeply trenched.

Fibrous-rooted Begonias.—If these are required for bedding purposes, seed should be sown this month. The plants make very effective bedders, and some of the newer varieties have very dark-tinted ornamental foliage, which makes the plants useful as edgings to beds of variegated-leaved *Pelargoniums*.

Antirrhinums.—If seeds of the Tom Thumb varieties be now sown, the plants will be available for bedding-out this season. The yellow varieties of this section bids fair to supersede the *Calceolarias* as a summer bedder, it is entirely independent of the weather, and continues to flower till quite late in the autumn. The seed may be sown very thinly in pans, which may be placed on a shelf in a warm house till it has germinated, when cooler treatment must be adopted.

FRUITS UNDER GLASS.

By G. NORTHAN, Gardener, Hatfield House, Herts.

Strawberries.—Certain varieties appear to force with better results in some places than others. For starting at this date, Royal Sovereign has been the best here for several years past. Strong plants with well ripened crowns if started now may be relied upon to produce good crops of fruit in April. A Strawberry-house is a great convenience, and the plants' requirements can be satisfied without consideration of other species. But Strawberries may be forced with success in other properly-ventilated houses if given light positions, near to the glass. A newly started Peach-house is a suitable one for them. Before placing the plants in warmth, remove the dead leaves, and examine, and make good the drainage in each case. The surface of the soil should be made firm also with a potting-stick, taking care to use it effectively near the sides of the pots, so as to make good any space there may be, through the soil having shrunk. As a preventative of mildew, it is well to dip each plant in water containing about half a pint of sulphur to 2 gallons of water. When commencing to force, the temperature at night should be about 50°, and by day with fire-heat 55°, with a rise of 10° by sun-heat. Every alternate day is usually frequent enough to examine them, and tepid water should be given to all those which are in only a slightly moist condition. Each 6-inch pot should have an inch water-space at the surface, and this should be filled each time water is given. The soil must not be allowed to become dry at any time. Syringe the plants once on fine days only, especially on the under-side of the leaves. When the weather is dull and the air in the house dry, merely damp the floor. Before the plants have made young leaves, choose a calm afternoon to fumigate them, to destroy green-fly. Ventilate during the forenoon in degree as the temperature rises, and in the afternoon reduce it also gradually. If any of the earlier plants have commenced to open their flowers, discontinue syringing, and keep a somewhat dry atmosphere until the fruits are set, allowing as much ventilation at the top of the house as the weather will permit, and 5° more heat during the day than advised above for later plants.

Cucumbers.—Strong plants raised from seed, or cuttings in the autumn, may now be planted. To provide bottom-heat, there should be a chamber furnished with hot-water pipes. Over this chamber place about 9 inches of well-prepared hot-bed manure, and over this small mounds of soil, about a yard apart, along the front of the house, sufficient in quantity to cover the roots when planted. This soil may consist of three parts turfy-loam, to one of old Mushroom-bed manure. Allow this to become warm, and then put in the plants, and secure each one of them to a

one end of which should be inserted into the soil, and the other fastened to the trellis. After sowing, afford a thorough soaking of water, and maintain a bottom-heat of from 80° to 85°. The temperature of the house should be 65° to 70° by night, and 75° by day, with fire-heat, allowing a rise of 10° by sun-heat. Cucumbers require much moisture to the roots, and in the atmosphere. Examine the soil once a week, and if found to be approaching dryness, afford it a soaking of tepid water. Keep the surface of the soil damp by occasionally sprinkling it through the rose of a watering-can. Syringe the plants once on fine days, but more frequently as the season advances. When the plants have made growth, tie the leading stems loosely to the trellis, and pinch off the side-shoots until they reach the trellis. A sowing of Cucumber-seed may be made now. Sow the seeds in fine light sandy soil, eight seeds in a 5-inch pot, and cover with about quarter-inch of soil. After sowing, give them a gentle watering, plunge the pots in the bed between the Cucumber plants, place a piece of glass over each pot in case a mouse find its way into the pot. Remove the glass as soon as growth has commenced, and pot off when the second leaf can be seen.

Melons.—Seeds may now be sown for the first crop, and treated the same manner as that recommended for Cucumber seed.

Peach Houses.—Go over the blooms in the early house about noon each day with a camel-hair pencil, or rabbit's tail, to assist their setting, and for the same purpose the trees may be shaken slightly. Keep the atmosphere rather dry and buoyant, by having extra heat in the pipes in the daytime, with as much ventilation as the weather will permit. The temperature may be kept at 60° during the day, or 10° higher with sun-heat. From dusk it may gradually recede to 50° at daybreak. Damp the borders and paths once in fine days while the blooms are open.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

Forcing Potatoes.—The best results are obtained from hot-beds made up of stable-manure and tree-leaves, the latter forming the larger proportion; and while the material is undergoing preparation and fermentation, place a sufficient number of tubers of some early kidney in boxes or on the floor of a cucumber-house, or some other warm-house, placing some soil of a light kind or leaf-mould among them, and being careful to place the end in which are the "eyes" uppermost. When the shoots have grown in, in length, and they have been reduced to two, the tubers are ready for planting in the hot-bed. A hot-bed for forcing Potatoes should be erected 2½ to 3 feet in height, and 1 foot wider than the frames. When the frames are placed on it, a layer of light mould 4 inches thick should be put inside, and when this has got warmed throughout, plant the tubers 6 inches apart, proceeding in this manner till the frames are planted, and cover the tubers with light, dryish mould, nearly up to the lowest leaf on the sprouts. It is an economical practice to sow seed of some early kind of Radish between the rows, these roots being ready for use before the tops interfere with the Potatoes. Afford water when the soil indicates dryness; cover the frames at night with mats and litter, according to the state of the weather, removing all covering as soon as it is safe to do so, and afford air in small quantities in mild weather. The day temperature may be anything between 65° to 70°, and that of the night 55°.

Carrots.—A mild temperature only is wanted to force this useful and much-prized root, and the forcing may be done in pits or hot-beds, as made for Potatoes, the depth of materials being a little less. Let a layer of sandy loam 7 inches deep be put into the hot-beds, and when this has got warmed, sow the seeds thereon, after levelling and forming it. Let the seeds be lightly covered to the depth of a quarter of an inch with light soil pressed firmly. Keep the frames close till the seeds are up, when air should be admitted freely in mild weather, and maintain the warmth of the bed by securely covering the glass at night. Top heat may at the first be kept up by placing a lining of litter round the bed if it be an ordinary frame hot-bed made above the ground. But this may not be necessary if it be a brick pit. If the heat of the bed declines sensibly, stronger linings of fermenting dung and leaves must be employed, as no good results will follow if the bed gets cooler than 70°, and this holds good for all sorts of hot-beds for vegetables. The night warmth should be kept between 55° and 58° for the present, and this needs that

the frames be suitably covered at night, as well as slightly ventilated.

Seedroom.—Now is the time to make an examination of all the seeds left over from last year, saving those that are likely to afford a large percentage with germinative power. The extreme time during which seeds of certain vegetables and herbs retain their germinating power is as follows:—

	Years		Years
Angelica	1 to 2	Lavender	4 to 5
Basil and Lettuce	1 to 5	Marjoram and Sage	2 to 3
Cauliflower	3 to 5	Sea Kale	1
Broccoli	3 to 4	Melon	5 to 8
Beans, Kidney	3 to 4	Parsley	2 to 3
Marigold	3 to 7	Leek	2 to 3
Carrot	3 to 4	Beans, Broad	4 to 5
Chicory	6 to 8	Radish and Turnip	5 to 6
Coriander	4 to 5	Scorzonera	2
Endive	4 to 5	Onion	2 to 3
Peas, small round	3 to 4	Spinach, ordinary	4 to 5
" Marrowfat	2 to 3	Celery	
Tarragon	2 to 3	Celeriac	5 to 6
Cucumber	6 to 8		
Kohl-rabi	5 to 7	Rosemary	2 to 3
Cabbage and Brussol		and Thyme	
Sprouts	4 to 5		

Before old seed be made use of, its germinating power should be ascertained by sowing some of it in pans placed in a mild hot-bed, counting the seeds sown, and noting the percentage of those which grow. The whole of a parcel of seed may be older than the gardener assumes it to be; or a portion of it may be old, and the rest a part of the last harvest but one, and this fact should not be lost sight of. Having sorted out what is to be kept, wash and otherwise clean drawers, cupboards, and every part of the place.

Buying Seeds.—Look carefully over the list of seeds you purpose ordering from the seedsman, study the requirements of the establishment, and order no more than is necessary. Let some novelties be tested, but grow the more popular varieties for the main crops, and buy the best.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Hippeastrum (Amaryllis).—Carefully shake out some of the largest and longest-rested bulbs, and repot them in moderately moist soil, and withhold water till growth begins, plunging the pots in a gentle bottom-heat, and keeping each in it till the flower-scape is well advanced, when the pot may be gradually withdrawn, and finally removed to the greenhouse when the flower is expanded.

Lily of the Valley.—Let a succession of flowering plants be kept up by putting a batch into heat at fortnightly intervals, or according to the demand. Cover the crowns with wood-moss till growth commences, afterwards removing the moss, shading slightly for a time, so as to draw up the leaves and flower-spikes, gradually hardening off the plants as the bells open.

Spiraeas.—Afford these plants the same kind of treatment as that advised for Lily of the Valley. Plants which are growing freely and are well rooted require frequent applications of manure-water, in order to ensure strong flower-spikes and good foliage.

Deutzias.—Place plants in gentle heat for successful flowering, syringing them freely, but affording root-moisture in moderation till leaf and shoot-growth commence, when more may be afforded, also manure-water occasionally.

Rhododendrons.—Some of the early-flowering varieties should be brought into heat, and where house-room is ample, large plants may be lifted from the beds, not tubbing or potting them, but placing them in flat hampers, or in boxes, or on the floor, and simply covering the roots with soil and affording a good soaking of water. It is very necessary to guard against lack of water at the root at any time, otherwise the flower-buds of Rhododendrons fail to open satisfactorily or they drop.

Azalea mollis.—The same kind of treatment as that advised for Deutzia suits this section of Azalea.

Lilium longiflorum var. Harrisii.—The plants should be kept near to the glass, and care taken that they do not suffer from lack of water at the root, and be afforded a temperature of 40° to 45° at night, with plenty of air during the day, but avoiding cold draughts.

Freesias.—Red-spider is the worst enemy of the Freesia, and if these acari are once allowed to take possession of the leaves, the latter are soon spoiled, puny flower-spikes being the result. Let the potfuls of bulbs be placed in a gentle heat, thoroughly

syringing them once a day till the flower-spikes are well above the soil, when they should be removed to cooler quarters; manure-water may be occasionally afforded well-rooted potfuls.

Dutch Bulbs.—The stock of these bulbs that is plunged in coal-ashes out-of-doors, will in many cases have filled the pots with roots, and be growing more freely now, rendering an examination advisable. Those that are well-rooted, should be placed in a cold frame for a few days, and shaded, until the leaves have changed to a green tint. Batches of the bulbs thus prepared may be removed to a warm-house or forcing-pit, in order to complete their growth.

Pelargoniums which are growing freely may be shifted into their flowering-pots, using a compost of good friable loam and sand, with a sprinkling of bone-meal; pot firmly, to ensure a short, stocky growth. Place close to the glass, in a temperature of 45° at night, giving air at every suitable opportunity, fumigating on the first appearance of green-fly. The shoots should be suitably staked out as they extend.

THE HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Planting of fruit-trees should be continued during mild weather, and when the soil is in a fit condition. The soil may be lightly trodden, but do not make it too hard when moving it in the winter. No manure should be used when planting, but if the soil be poor, replace part of it with some good turfy-loam from an upland pasture, preferably from one that is resting on red sandstone. Excepting Cherries, all fruit-trees do well in such loam, and it will keep sweet for a long time. Cherries require more lime than is contained in a sandstone soil, and it can easily be added in the form of mortar-rubbish or broken chalk. These substances are also of great benefit to all stone fruits. When the trees have been planted, fasten them securely to prevent them from being swayed by wind or other cause. Trees against walls should only be temporarily fastened to allow for the soil sinking after heavy rains, but Peaches, Nectarines, and Apricots, must be kept closely to the walls until all danger of severe frost is over. Give to all recently-planted trees a mulch with stable-manure or half-decayed leaves, and extend it 1 foot wider than the extremities of the roots; this mulch will hinder frost from penetrating, and encourage an early root-action. Where protection from cattle will be necessary, it should be supplied at once, and the iron and barbed wire-protectors are superior to the old-fashioned wooden cradle, being practically indestructible. Some Kentish growers make a protector from the smaller portions of old Hop-poles, which are cut off in about 6-feet lengths, and then bored through about 18 inches from each end; a piece of wire is threaded through each of these holes, and the ends are joined when enough poles are fixed around the tree, thus forming a long tube, which lasts for several years, and forms a protection against rabbits and hares, as well as larger animals, and also shades the stems from hot sunshine.

Root-pruning is sometimes necessary in the cases of bush and pyramid Pear and Apple trees, and Pear and other fruit-trees on walls. Should the trees be growing vigorously year after year, and remain unfruitful, it is useless to continue pruning above-ground, for thereby growth is encouraged instead of restricted, and the remedy will be found in the discontinuance of pruning entirely, or by cutting off some of the roots. In cases where the tree has to be confined within a certain space, the latter remedy is the only one possible. Small trees not more than 5 feet in height may be lifted entirely, and if the fibrous roots are carefully preserved, they will continue their growth in a modified manner, and form fruit-buds the first season. This operation causes so great a check, that it is best to prune half of the roots one season, and the remainder twelve months afterwards. Take out a trench 6 feet from the stem of the tree upon one side, and make it 2½ feet deep, then work towards the centre with steel forks, preserving the fibrous roots, and cutting off all strong ones having a downward direction. When the roots have been exposed, trim all jagged ends, and if the quantity of roots is excessive, reduce them by removing the coarsest ones. In replacing the soil, lay out all the roots in regular order, and do not allow the points to trend downwards. An admixture of charred garden refuse—one part to five parts of the soil—will be beneficial, and when all is filled in, mulch the surface with strawy litter of half decayed leaves, and secure the tops with wires.

EDITORIAL NOTICES.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

APPOINTMENTS FOR THE ENSUING WEEK.

SALES.

MONDAY,	Jan. 10	{ Border Plants, at Mr. Stevens' Rooms.
TUESDAY,	Jan. 11	{ Continental Plants, Herbaceous Plants, Roses, Gladioli, &c., at Protheroe & Morris' Rooms.
WEDNESDAY,	Jan. 12	{ Japanese Lilies, Azaleas, Roses, Spiraeas, &c., at Protheroe & Morris' Rooms.
THURSDAY,	Jan. 13	{ 200 Cases of Japanese Lilioms, &c., at Mr. Stevens' Rooms.
FRIDAY,	Jan. 14	{ Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—36°5°.

ACTUAL TEMPERATURES:—

LONDON.—January 5 (6 P.M.): Max., 54°; Min., 48°.

PROVINCES.—January 5 (6 P.M.): Max., 54°, south-west Ireland; Min., 38°, north-east Scotland.

So far as we know at present, the Quinquennial to be held at Ghent from the 16th to the 24th April next, promises to be the great horticultural event of the season. Unlike the brilliant series of shows held last year at Hamburg, the great display at Ghent lasts but nine days—a nine days wonder! It is, nevertheless, so far as British horticulture is concerned, a more important meeting than that at Hamburg, and it is still one of great moment, though the volume of trade from Belgium to England is less than it used to be before our cultivators found out that they, too, could grow on a large scale, plants which were formerly thought to be a monopoly of the Belgians. How many hundreds of nurserymen there are around Ghent we cannot compute. Many of them are our very good friends, their establishments are always very well worth seeing, and their hospitality—especially at the quinquennial periods—is only too overpowering. Moreover, there is a school of horticulture to which, in default of any of our own, our nurserymen are wont to send their sons. One of our English nurserymen, Mr. SANDER, has established in the neighbouring town of Bruges, a nursery on a large scale, which, together with those in Ghent and Brussels, will attract many visitors from this country.

The exhibition itself will be a reflex of the horticultural activity of the kingdom. There will be seen the noble Palms, Cycads, Tree Ferns, for which there seems to be so little relative demand in this country. There will be the Camellias, all but extinct here (save for the fine collection at Waltham Cross, and some few others). Azaleas, both of the indica and of the mollis sections, will be in profusion; and besides these staples, something of everything.

It is to be hoped that our own exhibitors will, as in former years, show what they can do. Orchids, Cyclamens, Chinese Primroses, Cinerarias, and other things, can be sent from this side of the water without much risk of being surpassed. The show, we may mention, is open to all nationalities, to amateurs, and to the trade. The jury is international, and consti-

tutes a true "concert of Europe," which does know its mind, and how to act as one body. The applications for space should be made not later than March 19, to M. FIERENS, the Secretary. In the programme before us there are 28 groups, containing 716 classes, first, second, and sometimes third prizes being allotted to each class. New plants constitute the group to which most interest attaches. Next come Orchids, stove plants, foliage and floral; Aroids, always a feature at these shows; Palms, usually shown splendidly; Cycads, Pandanads, Tree-Ferns, greenhouse plants, forced specimens, hardy plants, bulbs, trees and shrubs, pot-Vines, forced Strawberries, and miscellaneous exhibits far too numerous to mention, but which may be found in the programme, to be had from M. FIERENS, Casino, Ghent, as before said.

We shall keep our readers informed as to any further particulars that may reach us.

The Weather
and the Fruit-
trees.

THE vicissitude of the weather in these islands is proverbial, and to scarcely anyone is this of so much importance as to private gardeners and fruit cultivators, and especially to those who have extensive walls planted with fruit-trees of all kinds, which are naturally expected by the owners to furnish full supplies of the finer fruits for dessert purposes. The chief danger to be feared this mild season is the excessive forwardness of growth and flower, and the nipping frosts of late spring. In the case of wall fruit-trees, it is evident that the timely unfastening of the branches from the wall, and the postponement of the pruning till the latest possible period, would have the effect of keeping flower and wood-buds dormant, whereas early pruning and nailing would be followed with exactly opposite effects; and having started the basal dormant buds into growth, no further relays are obtainable. Hence we advise delay this season, and the concentration of the labour, unfortunately not too abundant in any garden nowadays, on the carrying out of all seasonable operations, in tree-planting, digging, trenching, and manuring land, and generally in bringing work of all kinds up to date and beyond it, if possible.

Where the complete detachment of the branches and shoots from the wall can be carried out, the more will the tree be removed from the exciting influence of the sun's heat, and the longer the period of bursting into flower and growth be delayed. There is still another method by which rapid advance can be checked, and that is to leave the pruning untouched, and to cover the forwarder kinds of fruit-trees thinly with Spruce Fir branches, nailed to the wall; or to make use of the ordinary blinds and coverings during the day; and so long as the trees are not in bloom, to roll these up during the night, however cold it may chance to be. Having done these things, we must trust to Fortune, and hope for the best.

With orchard and free-standing trees and espaliers, little can be done either in preventing growth, or in retarding it after it has begun. Certainly, in the case of espalier Pears and Apples, a broad board fastened on the top of the fence forms a capital protection against frost after the bloom has burst forth, and the branches of Spruce Fir, Laurel, or Yew, stuck into the soil on either side of an espalier would help to screen it from the sun's warmth; on the other hand, they afford shelter against the cold by preventing radiation from the plant, so that the advantages are problematical at the best. In some cases we

might adopt American and Continental methods, and light smoulder-fires on the windward side of an orchard or a fruit-plantation when frost is imminent, the dense smoke from the fires acting like the clouds in hindering the radiation of warmth from the ground, and giving out, moreover, a slight degree of heat.

Earthenware
Hot-water
Pipes.

A CORRESPONDENT at Cheltenham forwards, for our inspection, a photograph of a span-roofed pit at Pittville, in that town, heated by means of glazed earthenware pipes, resting on bricks laid at short intervals apart on the ground. The method is not new, although the manner in which they are put together exhibits a novel feature. The usual mode of joining the lengths of pipe is to put in a thin luting of clay at the point where the end of a length of pipe abuts on the bottom of the socket of another, and then, having placed the pipe in its proper position, to pour in Portland cement, so as to form a watertight joint. The pipes used are made without sockets; and the joints are formed of two cast-iron rings, each of which fits the pipe at one end, and the larger diameter of one is of such size that it exactly fits into the larger diameter of the other. A piece of tape wound round the junction of the two pipes prevents anything passing into the interior. After the rings are in place, Portland cement is poured in so as to fill the space between the iron rings and the pipes.

Amongst other advantages, the economy of using stoneware instead of cast-iron pipes is considerable, the difference being, says our correspondent, about 50 per cent., in addition to the fact that the joints can be made by an ordinary garden labourer.

Pipes of this kind are practically everlasting, provided they are out of the way of blows from falling pots, bricks, and the various objects that seem to be always lying in wait, as it were, to bring about the destruction of ficile wares. They would, however, answer admirably as a means of affording bottom-heat to Cucumber, Melon, and Pine-beds, warming tanks in aquaria, imparting heat to Asparagus-beds in the open-air; and in other positions where accidents to them are but little likely to happen, or where, from excessive moisture, the life of cast-iron pipes is of short duration. We have used earthenware glazed pipes of 8 to 10 inches in diameter as hothouse flues with satisfactory results, these being removed from chance of breakage by being placed beneath the plant-stages and benches. They are much to be preferred to the brick or tile-flue which, however well it may be constructed, is a source of danger to the plants from its liability to emit smoke and other products of combustion into the glass-house through some of its many joints. By having pipe flues constructed with close-fitting soot-doors every 15 or 20 feet, it is an easy matter to clear them of soot.

A GRAND PLANE TREE, AND OTHER TREES, AT MOTTISFONT ABBEY.—The two different views (figs. 9, 10) of a very large *Platanus orientalis* (Common Plane) were kindly sent us by Mr. G. MEINERTZHAGEN, in whose garden at Mottisfont Abbey, Romsey, the tree is growing. In the note accompanying the photograph of the trees, Mr. MEINERTZHAGEN says:—"The re-rooting of the branches is very marked. The Plane-tree is, I believe, the largest in England, measuring round the trunk at 4½ feet from the ground 29 feet 8 inches. From tip to tip of the branches it covers 129 feet. There is only one branch allowed to take root, the others being propped up to keep the space open under the tree. A

tree of Spruce Fir growing in the same garden, has produced from a branch, a tree three-quarters of the height of the parent tree, which seems now to be dying, the offshoot being strong and vigorous. Two other stems of this same tree have had the intervening branch severed for some years, and are now growing well. A Chestnut-tree [of which a photograph was also sent. ED.] has taken root in nine places, each branch producing quite a good-sized tree, the whole covering a large area of ground."

ROYAL HORTICULTURAL SOCIETY.—The first meeting of the committees of the Royal Horticultural Society in 1898 will be held, as usual, in the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday next, January 11.

GARDENERS' ORPHAN FUND.—Some complaints have reached us to the effect that cards soliciting votes, and mentioning the names of certain subscribers as nominators, have been issued before any official announcement from the committee has been circulated. We suspect the nominators are within their rights, but it is a right that it were better not to exercise—in order to avoid friction and unpleasantness.

HORTICULTURAL CLUB.—The usual monthly dinner and *conversazione* will take place on Tuesday, the 11th inst., at 6 P.M. The subject for discussion will be, "The Seasons of 1896-97; their Lessons and Effects on the Fruit Crops and Trees." To be opened by Mr. GEORGE BUNYARD, V.M.H.

THE CLIMATE OF BUTE AND OF KENT.—At this season of the year it is customary for the great trade houses—and the little ones too, for that matter—to gather together their *employés* at a social gathering, when the anxieties of business are for a few hours dismissed, and reciprocal goodwill and enjoyment take precedence. We receive numerous reports of such gatherings, which our space forbids us to insert. They are naturally principally of a personal character, and not of public interest; while to make advertising capital out of such matters is to spoil their essential characteristic. Nevertheless, at some of these gatherings some interesting facts are elicited. Thus, at the gathering of DOBBIE & Co., it was stated that Mr. DOBBIE began business with half an acre of ground—a parallel to the small cabinet

FIG. 9.—PLANE TREE SHOWING ONE BRANCH RE-ROOTED, AT MOTTISFONT ABBEY, ROMSEY. (SEE P. 24.)

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The committee has decided to hold the annual friendly supper of the members of this institution and their friends, at Simpson's, 101, Strand, on Thursday, January 20, at 6 p.m., after the Annual Meeting, when ARTHUR W. SUTTON, Esq., of Reading, will preside. Friends who are desirous of being present at this, the 60th Annual Meeting, are requested to intimate their intention to Mr. GEORGE J. INGRAM, Secretary, 50, Parliament Street, S.W.

—We have much pleasure in announcing that His Grace the DUKE OF PORTLAND has kindly promised to preside at the 60th Anniversary Festival Dinner of the Gardeners' Royal Benevolent Institution to be held, it is hoped, in June next, but the date is not yet fixed.

THE MOST EMINENT ORDER OF THE INDIA EMPIRE.—Botanists and horticulturists will rejoice to hear that Brigade-Surgeon-Lieutenant-Colonel GEORGE KING, Superintendent of the Calcutta Botanic Garden, has been promoted by Her MAJESTY to be Knight-Commander, and will henceforth be known as Sir GEORGE KING.

CHEMISTRY OF HORTICULTURE.—It is reported that the Royal Horticultural Society is about to appoint a professed chemist, whose duty it will be to furnish analyses of soils, waters, manures, &c., at a relatively low price, to Fellows of the Society. We believe Dr. VOELCKER, who holds a similar position in the Royal Agricultural Society, will in the future act also as Consulting Chemist to the Royal Horticultural Society.

that was the germ of the great firm of SUTTON'S. The contrast between the climate of West Kent and that of South-west Scotland was strikingly illustrated by Mr. FIFE, who said that their experiences in the south had been very varied. They had had variations in climatic conditions which he believed they rarely experienced in Bute. In the last three years he had been privileged to be in the coldest climate he had ever experienced, with a temperature at least 8° or 10° below zero; and he had also been in the hottest climate he had ever endured. He had seen it rain as he had never seen it rain in Scotland, and he had seen a drought with the land so dry that no one in Bute could realise.

AGRICULTURE IN ABERDEEN UNIVERSITY.—Short courses in agriculture and allied subjects,

intended specially for young men who would not think of taking out a full university course, but who could conveniently attend a month's course of instruction in the depth of winter, when work is slackest at home, are to open in Aberdeen University, on January 10. In addition to lectures on subjects likely to be useful to agriculturists in the north-east of Scotland, instruction will be given in the laboratory in the chemistry of manures and soils, and also with regard to the identification of grass and other seeds, and with practice in germinating seed. Saturday visits are also contemplated to farms in Aberdeenshire and Forfarshire.

THUYA PLICATA (GIGANTEA).—A portrait of the base of the trunk of a remarkable specimen of the so-called Red Cedar of the north-west coast (*Thuya plicata* or *gigantea*) is published in a recent issue of *The Pacific Rural Press*. This tree stands near Snoqualmie Falls, on the Seattle and International Railway, and the circumference of the trunk at the ground is given as 100 feet 7 inches. As this is one of the slowest-growing of the western Conifers, this tree has probably lived for more than a thousand years. *Garden and Forest*, November 17, 1897.

CAIRO.—M. DELCHEVALERIE has published in the French language an account of the Ezbekieh Park at Cairo, in which the origin and progress of this park are briefly sketched. The area is about 8 hectares, and it has been simply and effectively laid out by M. DELCHEVALERIE and the late M. BARILLET. In the present pamphlet an enumeration of the more remarkable trees and shrubs planted is given. Among them are *Balanites ægyptiaca*, a native of the Sudanese desert, which requires no artificial watering; *Dalbergia melanoxylon*, from Abyssinia, has flowered and ripened fruit; the Banyan, *Ficus bengalensis*, is at home; *Bauhinia purpurea* and *Poinciana regia* embellish the gardens. The boulevards are planted with *Albizia Lebbeck*, the most elegant tree for the purpose, and easily transplanted, seeing that the bole alone is necessary, the head and the roots being cut away far off in Lower Egypt, and transported to Cairo—once planted, they speedily throw out new roots and new foliage.

MESSRS. HUGH LOW & CO.—One by one the old-established suburban nurseries are being ousted, and compelled to seek other quarters. We have been familiar with Low's, of Clapton, throughout our lives. Now it appears that it is, or soon will be, a thing of the past, and we shall have to speak of Low's of Enfield (Bush Hill Park). The locality is a secondary consideration. Messrs. Low & Co. will take with them their reputation, and that is of the highest.

WILLIAM PLUMB.—The newly-elected President of the New York Florists' Club, says the *American Florist*, was born in Huntingdonshire, England, in the year 1850. In early youth he was apprenticed at Sevenoaks, Kent, and his capability and fondness for his profession quickly brought him forward as a gardener of recognised ability. As a journeyman at Greenrold, Halifax, he won many awards at the local exhibitions. The first place he had full charge of was Swinton Park, Manchester, where he remained two years, and then came to America (he having visited this country for a brief time previously), and took charge of ROBERT COLGATE's place, and later on S. D. BABCOCK's estate, and several other large places at Riverdale, N.Y. He now superintends the fine estate of C. P. HUNTINGTON at Throgg's Neck. Mr. PLUMB has been for years an enthusiastic worker in the New York Florists' Club, also the S. A. F., and there is no man more popular among his fellow-members in both organisations than he. Fault-finding or contrariness find no place in his sunny disposition; he is uniformly cheerful under any and all circumstances, and always ready and willing to render a service when opportunity presents. No president ever came to the chair in the New York Club with more friends and fewer critics than President-elect PLUMB, and there is no doubt that a year of pros-

perity and advancement is assured during the coming administration.

JADOO.—The Report of the Agri-Horticultural Society of India mentions that Tea-plants in Cachar, grown in Jadoo-fibre, are taking a decided lead of the others in height, and a similar occurrence has been noted in the Society's garden. Mr. HELPS reports that Orchids show splendid roots when grown in this material.

VINTON'S AGRICULTURAL ALMANAC—"A Year-Book for Farmers and Landowners."—This is the successor to a similar publication issued by our late friend and colleague, JOHN MORTON. In addition to tables and calendars there are some very readable and useful articles, such as Mr. CLARE SEWELL READ's reminiscences of farming in Norfolk, and such a mass of information that the "almanac" may be called encyclopædic.

QUEENSLAND NEPENTHES.—Mr. F. M. BAILEY, the Colonial Botanist of Queensland, figures and describes in the *Queensland Agricultural Journal* two species of *Nepenthes*, viz., *N. Kennedyi*, F. v. M., and *N. Bernaysii*, Bail. Four Australian species are now known, and will doubtless soon make their appearance on our exhibition tables.

ALLOTMENTS IN THE COUNTY OF SURREY.—The Technical Education Committee of the Surrey County Council seem desirous of doing much more than has hitherto been done by that enlightened body, to give additional interest to allotment cultivation, and also to have all the principal groups federated, to some extent, so as to secure for them, as frequently as possible, oversight and "pointing," on the County Council basis, by the recognised instructors and experts. Hitherto, these horticultural teachers have been empowered to visit such groups of allotments as they may be invited to do so by the local committees. These groups have been pointed according to the recognised scale, and in that way their progress or otherwise could be determined yearly. The Technical Education Committee, as the result of this judging, have occasionally granted Certificates of Merit to the best plots, although not twice to the same person; and distributed useful elementary books on gardening. These awards have, so far, been much appreciated. The energetic chairman of the County Council, Mr. E. J. HALSEY, is now anxious to have all groups of allotments in the county brought under the same supervision for identical purposes, believing that a considerable impetus to allotment cultivation and expansion would result. Mr. HALSEY hopes even to obtain eventually a federation of all the various district or parochial cottage-garden or similar societies in the county, and ultimately to have annually in one part or other of the county a county exhibition of allotment and cottage-garden produce. Circulars inviting acceptance of these proposals have been issued to all known societies in the county. What the result will be, time will show.

ACCIDENT TO MR. C. C. HURST.—We are sorry to hear that Mr. C. C. Hurst, junior partner in the firm of B. HURST & SON, Burbage Nurseries, Hinckley, met with a rather serious accident while hunting with the Atherstone Hounds, on Friday last. Mr. Hurst's horse, in taking a fence, jumped into a "blind" ditch, turned right over, and fell heavily on Mr. Hurst's head. Mr. Hurst who is suffering from slight concussion and general shock, is progressing favourably. It will perhaps be remembered that Mr. C. C. Hurst recently read a paper before the Royal Horticultural Society on "Some Curiosities of Orchid Breeding" (see *Gardeners' Chronicle*, (Oct. 16., p. 278).

"GARDEN AND FOREST."—We greatly regret to learn that one of the foremost horticultural journals of the world, and one for which advanced horticulturists and botanists had the greatest respect, has collapsed for want of adequate support; it was too good.—"With the present issue, which completes the tenth volume, the publication of *Garden and*

Forest ends. For ten years an experiment has been tried of publishing a weekly journal devoted to horticulture and forestry absolutely free from all trade influences, and as good as it has been possible for unto make it. This experiment, which has cost a large amount of time and money, has shown conclusively that there are not persons enough in the United States interested in the subjects which have been presented in the columns of *Garden and Forest* to make a journal of its class and character self-supporting. It is useless, therefore, to sink more time and money in a publication which cannot be made financially successful, and must, therefore, sooner or later cease to exist."

PUBLICATIONS RECEIVED.—*Farming World Year Book.*—*Cyclamens, and How to Grow Them*, a practical treatise, by F. C. Edwards, Sholebrooke View, Leeds; a useful little treatise that may be commended to beginners. — *Transactions of the English Arboricultural Society*, vol. iii., part iii., gives details as to the excursion of the Society into Norfolk in August, 1897. — *Journal of the Royal Horticultural Society.* — *The Journal of the Board of Agriculture.* — *De l'Emploi Populaire des Plantes Sauvages en Savoie*, par le Dr. Alfred Chabert. — *Tijdschrift voor Tuinbouw.*

A FRENCH GARDEN IN 1545.

(Concluded from p. 12.)

AREA ESCARIA.—In this there should be two beds, one for such vegetables of which the fruit is eaten, the other being for root crops.

PULVINUS FRUCTUARIUM.—The fruit-bed has *Pepo*, numerous kinds of Gourds, the Cucumber, and Melons, and the *citrullus* or colocynth of medical men. The author also alludes to the large Maltese Gourds, which are still cultivated there; and mentions a practice of watering Gourds with sugared water, by which the taste is improved, such being called "Pompons succarins," or Sugar-Melons. Of the Cucumber, there is the cultivated and wild, or *Cucumis asininus*. This last is the *Ecbalium agreste*, or Squirting Cucumber.

Mala insana, or fruit of the Mandrake.—This was eaten with oil, salt, and pepper. He also describes a sort with prickly stems and foliage. This would probably be *Solanum sodomæum*. He also describes the "male" and "female" Mandrake; of course, imaginary distinctions.

Strawberry.—The fruits, of the size of a nut, were eaten with cream or sugared wine. There was a mountain form, probably *Fragaria vesca*, var. *alpina*.

Rubus Idæus.—Both white and red Raspberries.

Coriander.—A new plant in French gardens; and Anise, used as a stimulant for the appetite.

Cinara.—"A kind of cultivated Thistle, the top of which, as it were a fruit, we eat."

Papaver.—Though often grown in a kitchen garden, it is not edible, but the seed is used to encourage sleep. Imagination must have effected this, for Poppy-seed, it is now known, does not contain the opium!

PULVINUS RADICARIUS, or the root-bed.

Radicula. Radish. The root raw, cut up small, with water and salt, provokes the appetite. He says some kinds are sweet, others acid, but does not mention different forms. Another *Raphanus*, which the Romans call *Armoracia*, has leaves like those of the cultivated Radish. A third *Radicula* the Greeks call *Struthion*, used for cleaning wool. "It is a spiny herb, with a woolly stem, a handsome flower, without odour, &c." This plant has been thought to be *Gypsophila struthium*, or *Reseda luteola*; but the above description (taken from Pliny) is inapplicable. Pliny adds, "it grows upon rugged rocky sites;" and describes it as an umbellifer. *Matthæus Sylvaticus* gives several opinions, but decides nothing about it. He wrote in 1480. In 1760 an umbellifer was cultivated for medicine under the name *Struthium* (Lewis, *Mat. Med.*).

Rapum or *Napum*.—Fr. "Naveau." Used for flavouring soups. The author compares the shape of the root to the corm of the *Cyclamen*. There were

sorts, one gritty to the teeth, the other very
et and yellowish.

Rapunculus or *Napunculus*.—This has a blue
ver. The root is to be seen on the tables of the
and luxurious. Some call it "Locust," or
ocust's-foot," from a likeness in the root, "whence
n they thought it to have been the food of John
otist in the desert, for it grows in uncultivated
ees." It is *Campanula Rapunculus*.

Scrophularia major has a root resembling the Ra-
nculus, most pleasant to the taste and scent."
arde figures this as a species of *Scrophularia* or
wort.

Paranip, Carrot, and species of *Panax*, a foreign
bellifer, with yellow flowers, and entire sub-

mander. It is *Teucrium Scordium* or Water Ger-
mander. Of other bulbs he mentions *Ascalonitas*,
"Des eschalottes," i.e., *Allium ascalonicum*. Bulbus
agrestis, "des Oignons sauvages," probably *Allium*
ursinum. "The most noble of bulbs is the Scilla,"
"Des Squilles," *Urginea scilla*, the medicinal squill;
Pancration, probably *P. maritimum*; *Asphodelus*,
called *Hastula regia* and *Albucus*, *Asphodelus*
ramosus of south Europe. From 10th to 15th cen-
tury, *Hastula regia* was the Woodruff.

Helenium, *Elicampane*, is the last plant mentioned
by our author. The book concludes with a short
treatise, *De cultu et satione hortorum libellus, et*
antiquorum agricolarum sententia præcipue collectus.
George Henslow.

have the largest crops; from both countries offerings
have already been freely made in large quantities;
the States seeds are clean, but lack size. The north of
France samples are the best we have seen from there
for some years, large-grained, and of good character.
As usual, there will be considerable quantities of the
very weedy small-grained seed from the badly-farmed
districts of the south of France. Canada has not at
present placed much on the markets, and neither
Germany nor Russia offers with the freedom they
have done for several seasons.

White Clover.—A fair English crop, but fine
samples will be scarce. The large American supply
that characterised last year's trade cannot be repeated;
but the German offerings are plentiful, especially of

FIG. 10.—LARGE PLANE TREE AT MOTTISFONT ABBEY, ROMSEY: TRUNK 32 FEET 7 INCHES; COVERS 129 FEET OF GROUND.
(SEE P. 24.)

date, oblique leaves, with a juice like *Opopanax*,
l grows best about water. As other kinds of
anax, the author includes *Asclepium*, *Chironium*,
gusticum, and *Sphondylion* (of Greeks); Fr.,
Panais sauvage."

Sisaron (Grk.), *Siser* (Lat.), Fr., "des cheruits,"
w spelt "chervis;" Eng., Skirrets.

Siser sisarum was introduced from China into
England in 1548; Daubeny (*Roman Husbandry*)
suggests that the *siser* of the ancients was *sium nodi-*
rum. This, however, does not agree with Gerarde's
ure. Pliny says the best grew in Germany.

Cepa, many varieties of Onion, white, red, large
l small, or "oignonettes."

Allium, Fr., "des aulx," *Scorodoprason* (*Allium*
scandens, acc. to Daubeny), and *Scordion*, lately
roduced. This plant the author describes as only
ving the odour of Garlic. It was called *Trixago*
ustris by the Latins, and has leaves like the Ger-

CLOVER AND GRASS SEED CROPS.

MESSRS. Hurst & Son, Houndsditch, London,
forward for publication the following estimate of the
stock of grass and Clover, and other agricultural
seeds, of last year's harvesting:—

English Red Clover and *Cow-grass* will vary more
in quality and character than they usually do, and we
are of opinion that the superior grades will be very
scarce. The eastern counties have by far the largest
crops, the southern, western, and midland counties
have in the aggregate a largish acreage, but the
samples from these districts that we have already
seen show inferior quality, not well-ripened, and the
yield per acre unusually small. Yearly, or rather
two-year old, seed, for there was only a small
quantity saved in 1896, is now almost exhausted.

Single Cut Cow-grass—Is in small supply.

Foreign Red Clover.—France and America seem to

the lower grades. The finest samples are undoubtedly
scarce everywhere.

Alsike.—Seems to be in much smaller compass this
year. For several seasons it has been abnormally
plentiful, Canada sending us heavy supplies; so far
this season the offerings are on a very restricted
scale, and the samples lack good colour. The German
crop we hear is an average.

Trefoil.—A smaller crop of English than usual;
and although the Continental crops are not up to an
average perhaps, the very large quantities of yearling
seed still held in this country will prevent prices being
high.

Lucerne.—Short crops both in France and America.

Sainfoin.—English Giant an under-average crop;
a fair supply of English common. French Giant is
reported scarce, and of generally inferior quality.

Italian Rye-grass.—The French crop is under
average, and fine Mayenne does not offer freely; the

re-cleaned qualities will be very scarce towards the end of this season. Irish crop again large, and of good quality. English quite up to average.

Perennial Rye-grasses.—Not quite such large crops as for several years past, but still plentiful. The natural weight per bushel lower than last year.

Natural Grasses.—Vary as usual. Cocksfoot is in fair supply from New Zealand, but we are not getting offers from America. Timothy still plentiful. Crested Dogtail in larger supply than for several years. Meadow Fescue very fine, but not so plentiful as last year. The Poas in short supply; this applies also to Sheep's and Hard Fescue.

ALPINE GARDEN.

NEW AND RARE PLANTS FOR ROCKERIES.

THE genus *Acæna* includes some very interesting little species, some of which are new introductions, and prove very hardy here at Geneva. For instance, the beautiful, small-growing *A. Buchanani*, Hook. f., nearly allied to *A. microphylla*, is a gem in rock-gardens. It is a very slow-growing shrub, caespitose, spreading over the soil, with a very pretty foliage of a light, almost sky-blue colour in the sunshine, and hardly at all green. The leaves (eleven leaflets generally) are delicately incised and crenate, and the whole tuft is exceedingly dainty. The flowers are not worthy of mention, being like those of the other *Acænas*, which are all inconspicuous. We received the seeds of this plant from Mr. Cockayne in New Zealand, who found it in the mountains of the Otago country.

Acæna glabra, Buchanan, is another newly-introduced species, for which we are indebted to Mr. Cockayne; the stems are erect, the leaves brownish-green, seven to eleven leaflets.

A Russian botanist, already well known for his discoveries in the Caucasus, Mr. N. Alboff, is now in La Plata, and has made some botanic excursions in "Tierra del Fuego" and "Magellan," whence he sent us last year a fine collection of seeds, from which already some results have been obtained. This has particularly been the case with a very good form of *Acæna adscendens*, with glaucous foliage, quite bluish, which seems to be very hardy, and easy of cultivation.

While speaking of *Acænas*, it might be said that it is an interesting genus for foliage, which is in all specimens good, and sometimes very ornamental. But I know few genera more polymorphous than this. A good little monograph upon them has been lately published in Paris by Dr. P. Citerne of Nantes.* Although their flowers are not attractive, *Acænas* can be recommended for the rock-gardens for their foliage, and for the long and graceful sarmentose branches many of them produce, especially the so-called "Bidi-Bidi" of New Zealand. *A. Sanguisorbæ*, Vahl, which is called sometimes Piri-Piri, Huty-Waij, or Piri-Kahu.

They are, I believe, all hardy in England, but in Geneva some of them have to be kept in a frame or conservatory for the winter. Fourteen species are now cultivated in Europe; Dr. Citerne enumerates forty-two species; and Mr. Alboff, last year, published † two new kinds—*A. tenera*, Alboff, and *nudicaulis*, Alboff. Their cultivation is easy; they like sunshine, but a fresh atmosphere.

Acanthosonchus spinosus, Forsk. (*Sonchus spinosus*, D.C.; *Lactuca spinosa*, Lam.), is a very small and thorny shrub, not more than 3 inches high, forming a Liliputian bush, with a few small leaves, and some little yellow heads, very similar to those of the common Lettuce, the whole being hidden by numerous short, spinose, and erect branches, which give the plant a very curious appearance. It grows between the rocks in North Africa, the Canary Islands, and Arabia. It is not hardy in Geneva, and

never seeds. I never saw this shrub in collections so I think it is very rare.

Alsine juniperina, Fenzl, is a pretty little caespitose plant growing in the dry rocks of Greece, Syria, and Palestine. The little branches spread over the soil, are prostrate or erect, and bear numerous fine and spiny leaves, fasciculated, and sometimes bear very numerous little white flowers from June till autumn.

Anemone rubra, Lam., is a very good form of the common *Pulsatilla*, which grows in the neighbourhood of Lyons, and of which the flowers are as large as those of *A. Halleri*, of a deep, velvety, garnet-red. It is a beautiful plant, easy of cultivation, requiring a soil destitute of lime, as the plant is a sand-loving species, which does not thrive on calcareous soil.

Antirrhinum glutinosum, Boiss. et Reut., is one of the best plants for the decoration of old walls or sunny perpendicular rocks. It is a good Snapdragon, of free growth. Its large white or pinkish-white flowers are very numerous, and open from June till the winter. I gathered to-day (November 26) a bouquet of the flowers from my wall, where two good plants have been established for the past five years. Some people in England to whom we sent it wrote that it cannot be considered as hardy in England; but this is an error, as the plant is very hardy here where the winters are more severe. I believe that the English fog or the dampness of the air must be prejudicial to it, and so I recommend it to be planted in a wall exposed to the full sun. Boissier found this plant fifty years ago in the rocks of the alpine regions in the sierras of South Spain. It has been cultivated in his gardens at Valleyres since that period, but I believe that the plant is very rare in gardens.

Aquilegia formosa, Fisch.—Under the name *A. arctica*, Hort. Loudon, the *Flore de Serres et des jardins de l'Europe*, Van Houtte, t. viii., published a coloured plate of the rare and fine *A. formosa*. Its stems are slender, and 2 to 3 feet high, almost naked, and bear at the base two or three leaves with narrow segments, glaucous beneath, and of a deep green above. The flowers are not numerous, but very pretty, long, narrow, with long and thin spurs, of an intense cinnamon-red, with green spots on the extremities of the spurs and petals. It flowers late, in July and August, and is quite distinct from all other *Columbines*. It has been said that this plant is the true *A. Skinneri* of Hooker, and corresponds to the No. 1182 of Pringle in the Kew Herbarium; this I cannot verify. The *A. formosa* (true) is rare in gardens, and De Candolle (*Prodromus*, vol. i., p. 50) says it is a native of Kamtschatka. But it has been found in the far north of America, and certainly grows in Alaska and other parts of Russian America, and of Canada. It belongs to the same group as *A. canadensis*.

Aster Amellus albus was found four years ago in Jura, and was introduced into cultivation through our garden. It comes true to seed. All the fruit harvested gives the white form, and not one returns to the type. *H. Correvon, Geneva.*

(To be continued.)

JAPANESE TREE-STRANGLER, OR STAFF TREE (*CELASTRUS AR- TICULATUS*).

CELASTRUS scandens from North America has long been known, but is not very commonly seen in our gardens. Our present plant is a smooth leaved and very free growing climber, just now covered with clusters of orange-yellow berries or capsules, which bursting open reveal the orange red seeds, as shown in the sketch sent herewith. The gracefully intertwined stems covered towards their upper extremity with fruits in all stages of colour and ripeness, make up a pretty little picture at Newry, where I lately saw this species for the first time sprawling about over some low-growing trees.

Planted near to any tree of no particular value or interest, such as a Crab or a gnarled old Hawthorn, and a most interesting and unique feature would soon be formed; or it might be tried on wood screens

and palings. Its growth is so rampant (*grimpaute*, the French call it, I believe), that only the most vigorous of living trees would be able to endure its double coiled and intertwined embrace.

To those who are on the look-out for a climber of the most luxuriant type, I should recommend this as being even more so in its tree-strangling propensities than is *Periploca græca*, or our own "Travellers' Joy" (*Clematis vitalba*). For covering pergolas, or gazebos in the garden it might prove useful, especially so in those peculiar sites in most gardens "where nothing will grow."

A cluster of scaffold poles, with their lower ends charred and set in concrete, might be employed instead of sacrificing a living tree. Such as pergola or "polarg" planted with this climber, *Periploca*, *Bridgesia*, *Travellers' Joy*, and the Common Hop plant could not fail to become covered with vegetable tracery, in a very short time.

My sketch (fig. 11) was made at Newry, co. Down, in October last; the only drawback to the fruitful beauty of the plant is that the birds seem extremely fond of its ripe seeds, and attack its fruits as soon as they burst open. Probably spraying with copper and lime solution would save the fruits of *Pyracantha*, *Cotoneaster*, *Mountain Ash*, and of this *Celastrus* if applied at the right time. *P. W. Burbridge.*

HOME CORRESPONDENCE.

"THE ROSARIANS' YEAR-BOOK:" A CORRECTION.—There is an error of some importance in the article entitled "Roses in the South-West of Scotland," contributed by myself to the *Rosarians' Year-Book*, for which I do not hold myself responsible, and which I certainly did not observe when I corrected the proof. If I did not take the opportunity of correcting this typographical mistake (which occurs on the last page of my contribution), it might be supposed by the readers of the *Rosarians' Year-Book* (most of whom are capable of detecting such an error), that I had included Turner's Crimson Rambler and Paul's Carmine Pillar among the Hybrid Teas! I need hardly say that such was very far from my purpose. *David R. Williamson.*

SULPHURING VINES.—The caution respecting burning flowers-of-sulphur in vineries is necessary to the inexperienced; still, sulphuring can be done if judgment be used. When living at Blairquohan Castle Gardens, forty-nine years ago, the then gardener, Mr. George Hunter, used annually to burn flowers-of-sulphur in the vineries after they had been started a week or ten days. He wished to revive any insects that might be on the Vines, and then kill them. Of course, the buds of the Vines had not pushed out sufficiently to be injured. I never saw any harm done to the Vines, but some of the fumes of the sulphur escaping through a partition into a greenhouse, laid their mark on a Banksian Rose trained on the top and against the back wall. I have never tried this method here, as our vineries are never free of plants in leaf. I have, however, found sulphur to be of great use in vineries. Thirty-five years ago we had Vine-mildew here very badly. I used sulphur with the sulphurets on the leaves, as recommended in the *Gardeners' Chronicle* of those days, which checked it a good deal. I also put a rather heavy dusting on the flues, and made them very warm so as to cause the sulphur to bubble on them, but not to burn. This would cause a mist in the house, the sulphur evaporating. Vine-leaves within 3 feet of the flue would not be injured, but the mildew entirely disappeared. This requires great caution, or damage may be done; indeed, it should not be attempted while the berries are small; they must be at least half-grown. *John Barnett, Decker Hill, Shifnal.* [Our readers, after conning the above, will be wise if they use sulphur in vineries with the utmost caution. Ed.]

APPLE ROYAL SNOW.—I was pleased to see the remarks respecting this Apple in your last issue. For some years I grew the variety on my fruit-farm at Stoney Creek, Ontario, Canada, where it was an abundant bearer, and the perfume and flavour of the fruit was excellent. Since commencing fruit-growing in Kent, I had decided to introduce it into this country, and now I see that Mr. W. Horne is also about to do so. I shall anxiously await the contest that will come between Royal Snow and Cox's Orange

* "Du Genre *Acæna*," par le Dr. P. Citerne, dans *Revue des Sciences Naturelles de l'Ouest*, 1897, Nos. 1, 2, et 3.

† "Contribuciones à la Flore de la Terre de Feu," dans *Revista del Museo de la Plata*, t. vii.

in, at the Royal Horticultural Society's fruit show. It is the only serious rival that Cox's Orange Pippin is likely to have for some time. *C. Aitken, Fruit-Grower, Orpington.*

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Besides electing under Rule 3 no fewer than twenty-five subscribers for pensions, all of whom have been subscribers or life members of the institution for fifteen years and upwards, the committee also invite votes from subscribers to enable nine others to be elected by ballot, and they issue a list of forty-four applicants for pensions from which those nine are to be selected. Looking over that list carefully, I have no doubt every one is a deserving one, and I find that whilst twenty-

year. It is indeed pitiful to find how many distressing cases there are in the ranks of gardening, but all the more forcibly do they show the necessity of making better provision towards old age than many seem to have done. Even of those subscribers up for election, the greater number seem to have deferred subscribing until sixty years of age and upwards. *A Subscriber.*

PLANTS THAT SUCCEED UNDER THE SHADE OF TREES.—Kindly allow me to add a few names of plants to Mr. Herrin's list, which I find grow well here in Devonshire, planted beneath the shade of tall coniferous or deciduous trees that have lost their under branches. Most of the bushy Veronicas

gardeners) to convey cut flowers of border Carnations to a provincial show. I am a subscriber to four up-to-date societies, although I have not taken any active part in their management for some years past; nevertheless, my love for all appertaining to my long-cherished profession burns with the same vigour as in the days of Auld-lang-Syne, when the vast and grand gatherings used to take place at Chiswick, Surrey Gardens, Cremorne, Stoke Newington, and many other localities, at which places I have met hundreds of exhibitors and friends, who have long since been consigned, with the lovely plants shown, to mother earth, and who have left records behind that exhibitors may do well to imitate and follow. I am led to believe that all those who have the welfare of the National Chrysanthemum Society at heart will do well to read thoroughly and attentively, and digest all that has from time to time been advanced by your correspondent, Mr. R. Dean, the indefatigable secretary of the National Chrysanthemum Society. I am fully in accord with all he stated in your issue of last week (p. 14), as I am convinced from past experience that it is not always wise to put a certain limit to entertainment when it is sought to gratify the various tastes of the general public. I have had on many occasions exhibits in spacious halls and tents, when those who had taken great pains to provide a good display had for their disinterested painstaking the most discouraging results; and it is patent that it is seen that not only in the metropolis but in very many large provincial towns, villages, and hamlets, an amazing advance has been made to instruct and entertain visitors with a cheerful and varied entertainment. If we are constantly looking upon exhibits of a similar description and character, the mind becomes tired and satiated, and to dwell upon stands and tables of cut Chrysanthemums, very much of a similar character, becomes tiresome, hence it is a wholesome change to be led to an exhibit such as Messrs. H. Cannell display with their grand collection of zonal Pelargoniums, in my estimation one of the leading features in the whole show. Then, again, how grandly are fruits and vegetables shown—dispense with these extras, and the seductive strains from the band engaged, and the varied means employed to make us feel our blood tingling through our veins in full zest of innocent enjoyment. It is well to pause, as it may happen that to leave a comparatively suitable home may lead to very unsatisfactory results. *G. F., F.R.H.S., Lewisham.* [The writer, to whom we offer our compliments and congratulations, has been a subscriber to the *Gardeners' Chronicle* since its foundation in 1841. *ED.*]

— Mr. Dean disagrees with my statements, see p. 448. I need only refer him to letters written by himself in recent numbers of *The Journal of Horticulture*. The way in which the National Chrysanthemum Society has grown and prospered, has not to my knowledge been questioned, and Mr. Dean says this has happened since its association with the Royal Aquarium, Westminster; the fact of the Aquarium Company reaping much of the benefit from the shows cannot have helped the progress of the National Chrysanthemum Society; the Aquarium Company pockets the profits, the contributions of the members thus go towards providing shows for its benefit instead of forming a reserve fund for the National Chrysanthemum Society, and the further encouragement of Chrysanthemum culture. As to the entertainments provided, I have nothing to say against music-halls as such, they are doubtless necessary for a certain class of people who cannot appreciate anything better, but Chrysanthemum-growers do not go hundreds of miles specially to enjoy miscellaneous exhibitions, although Mr. Dean says that those at the Aquarium form a source of attraction to members of the gardening profession. I cannot, however, agree with him; and I think that gardening has no connection with these things. Those few who wish for music-halls can get them nearer home or at other places in London; we, on the other hand, desire to see the flowers under the best possible conditions, to observe the newest and the finest varieties, and the highest points of beauty to which these varieties attain. To talk of mutual converse, warmth, light, and life is only attempting to throw dust in the reader's eyes. Could not all these things be got in another building, and in greater perfection? At present, the beautiful flowers are simply degraded by their surroundings, and have no field for exercising the influence peculiar to them. Moreover, a better class of visitors who would patronise the shows if held under better conditions, is kept away. As to other shows that have failed, reasons could easily be given for most of those

FIG. 11.—CELASTRUS ARTICULATUS: SEEDS YELLOW. (SEE P. 28.)

(From a sketch by Mr. Burbidge.)

free of the number have been, or their representatives have been, subscribers for varying periods, of the remainder no fewer than twenty-one have no such qualifications. In face of these facts, may I suggest that the rules were so far altered as to order subscribing applicants or their widows only eligible for the ballot. The matter must sometime be faced, and is it not well to face it early? A list of forty-four applicants is at once an immense and bewildering list. In marking my paper I have voted for subscribers only, and for those who, having already got into four figures, seem to have some chance of election; many have no chance whatever of being elected for several years. A concentration of votes to subscribers would help to place those not elected into a better position another

thrive in such dry positions, and where fairly sheltered from cold winds. I am well aware these do not prove hardy in every county, but I can strongly recommend them for this purpose where they thrive outdoors. Another good dwarf plant is *Hypericum perforatum* [? *calycinum*. *Ed.*], an evergreen that increases rapidly in size, and flowers well under the shade of trees. I have also found *Berberis aquifolium*, *B. Darwinii*, and *B. nepalensis* do remarkably well in such situations, especially the first two. *J. Mayne, Bickton, Devon.*

A HALL FOR HORTICULTURE.—It has been my privilege in some way or other to have been associated with horticultural and floricultural societies since 1832 or 1833, when I was employed (as a boy

Mr. Dean mentions, but they do not apply to the National Chrysanthemum Society; with many of them it would have been more surprising if they had succeeded. *W. H. Divers.*

CALLICARPA PURPUREA.—This old Indian stove-plant was prominent in a collection of decorative, foliage, and flowering-plants, with which Mr. W. Howe, gr. to H. Tate, Esq., Park Hill, Streatham, won the 1st prize at the recent exhibition of the National Chrysanthemum Society, at the Royal Aquarium. Long shoots bearing cymose clusters of deep violet-tinted, glossy berries, were prominent, and being unusual, attracted much attention, many enquiries being made as to the name of the plant. Cuttings made from the shoots put forth in early spring from cut-back plants, strike as readily in a brisk bottom-heat as do those of the Fuchsia; and fruiting-plants can be obtained in a season with careful culture. *R. D.*

UNTIMELY BLOSSOMING OF THE WHITE-THORN.—I am sending a few sprays of the White-thorn (May in December), as an instance, among many, of the mildness of the season. The bloom is quite expanded, and young leaves appearing on some trees of the same at this place. The tree from which the sprays were taken is growing quite in the open, facing north [The Glastonbury Thorn. Ed.]. *G. Farmer, Beckford Hall Gardens, Tewkesbury, December 22.*

FRUIT JUDGING.—I do not agree with the remarks made by "Cornubian" in last week's *Gardeners' Chronicle*, p. 12. He says, where ripeness is specified in the schedule, "judges have no choice in the matter," adding, "but the preference for ripeness (even when out of season) is carried to excess in many cases where it is not demanded by the schedule, and where ripeness is a positive defect." Over-ripeness is a defect, but ripeness, i.e., the fruits being fit for table at the time they are being judged, is certainly not a defect. "Cornubian" says: "Time and again I have seen fruits that were ripened out of season placed before others that were in every way of better quality, but not ripe." How could the unripe fruits be "better" in every way than the specimens "ripened out of season" which the judges preferred? Assuming the fruits shown to be of the same variety, equal, or nearly so, in size and shape, the preference undoubtedly should be given to the ripe fruit. "Cornubian" asks, "which is the most valuable dish, say, of Marie Louise, dead ripe in September, or a similar dish at the end of October or in November?" If both lots of fruit are "dead ripe" at the respective dates, one dish is about as valueless as the other. But a dish of well-developed fruits of Marie Louise artificially ripened in September is of more value by reason of its earliness than a dish of the same variety ripened on the shelves in the fruit-room a month or two later. Not only this, the Pears laid between layers of cotton or wood-wool in a shallow box, with the lid tied down, and placed on the trellis over the hot-water pipes in a vinery or Melon-house as the fruit is approaching maturity, will excel in colour those which ripen in the fruit-room; while the flavour, owing to the dry and buoyant atmosphere and warm temperature in which the fruit was ripened, is quite equal or superior. This I can vouch for from many years' experience in the matter. *H. W. W.*

CYPRIPEDIUM INSIGNE SANDERÆ.—Kindly allow me to reply to the remarks of "T. S." in your last issue. He tells us that part of the Pickering Lodge plant will be exhibited at the Royal Horticultural Society's meeting on January 11, and invites me to point out the difference between it and the true one. I may reasonably infer from this invitation that the variety I questioned has now developed into the true one, so there is little need for me to look at the original form, as I have seen it often enough. If the plant to be shown on this occasion is part of the plant they exhibited at Manchester Chrysanthemum show, in November, 1895, which was the Pickering Lodge plant, and named *insigne Sanderæ*, it will, indeed, be very interesting to learn how it evolved from that variety to the true one. If such is the case, perhaps "T. S." will kindly treat us to a short history of this fine science, as enlightenment on such points is much needed at the present time, seeing that several very curious cases of evolution has recently taken place among the more aristocratic forms of Orchids. I have already disclaimed any knowledge of their collection beyond what they show publicly—the *Cypripedium* in question excepted. *S. S., January 3.*

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The advantages offered to gardeners by this Society were described to the members of "The Beckenham Horticultural Society," at its last meeting by Mr. Burge of Oakwood Gardens. It transpired that few of those present knew much of the Society's work, although living not more than ten miles from the metropolis. Mr. Burge in the course of his remarks, pointed out that the Society consisted entirely of gardeners, and carefully explained the "Balance Sheet,"—the "Benefit Fund," "Benevolent Fund," "Voluntary Convalescent Fund," and the "Management Fund." The statement of accounts of liabilities and assets (the latter amounting to considerably over £11,000) caused some surprise, as did also Mr. Burge's statement that there is actually more money added to his account than he has paid into it. Having been a member for a number of years, his "Rest Fund" had accumulated until the interest amounted to more than the annual working expenses. Members can withdraw "Rest Fund" at the age of seventy years, "Lapsed" members at sixty years. In case of death, the sum passes to the person nominated by the member. *M. Webster, The Gardens, Kelsey Park, Beckenham.* [The ignorance our correspondent alludes to in above note is not due to any lack of sympathy on the part of the Horticultural Press, which has always accorded the business of the Society the publicity it so well deserves. Ed.]

THE PRUNING OF APPLE AND PEAR-TREES.—Mr. Ward, on p. 13, charges me with misrepresentation, and he has in no way substantiated his assertion. I contend that pruning-back leading growths to 5 or 9 inches is a very slow process in making a large fruit-bearing tree; and further, that many varieties of Apples and Pears will make far larger, handsomer, and more fruitful specimens in a shorter time, if left to themselves, than if subjected to such pruning. Then again, can you expect early fruit-bud formation, if these said 5 to 9-inch growths make three to five additional growths next year? In a good healthy young tree the buds should be 1½ to 2 inches from each other (excepting undeveloped ones at the base); therefore, all those buds that would have developed into fruit-buds if longer leading growths were left, have been forced unnaturally into growing shoots. The pruning of "misplaced" shoots back to 2 inches, is far too close for strong growing Apples and Pears, the said 2 inches would only have undeveloped buds, which experience has shown me make growths instead of fruit buds; whereas if they were left a longer length the buds would be more fully developed, and only one (seldom more) would make wood, the buds behind such being fruit-buds. The fore-part can afterwards be pruned back to the said fruit buds. Mr. Ward advises hard pinching in summer. I cannot agree with him, because in light soils it tends to keep the trees longer in growth in autumn when they should be maturing or ripening the growth made. In the case of varieties that fruit on the ends of the shoots, the 2 inch pruning would clear off the greater part of the crop, such, for instance, as the Irish Peach and Yellow Ingestre. Again, if the 5 to 9 inch system be practised, it will be years before you get a dozen fruits, and many more before you gather a gross. I prefer long growths and fruit—long spurs and fruit, rather than trees dwarfed with 5 and 9 inch pruning. In conclusion, may I be allowed to inform Mr. Ward that a great part of my horticultural education (which I admit is meagre) was learned from the *Gardeners' Chronicle*, and much from his own pen. *J. Kettle.*

COLONIAL NOTES.

TO DESTROY SNAILS.

AMONG the liberal contributions Australia has received from England have been sparrows and shell-snails. It may not be generally known that the latter may be destroyed by spreading a thin circle of Tobacco-dust, 3 to 4 inches wide, around the plants. Naturally those plants the snails most affect would be chosen for the purpose. The snails in crawling over the Tobacco-dust may be found next morning just outside the circle, and in the course of a few days become dried up.

I am aware there may be some difficulty in Britain in obtaining the material, as the Tobacco manufacturers return it all to the excise department

nominally for export but really for destruction. I do not see, however, why it should not be obtainable, as it is in these colonies, after the addition of say a little kerosene or superphosphate of potash, which would render it unusable for consumption.

The only material I have used so far for the purpose has been the fine dust, something like coarse snuff, but I think also the fine-cut Tobacco-stems which are returned to the Department in quite large quantities, might also very effectively be used. It is also in itself a splendid manure. It should be used preferably in dry weather, as its effectiveness is soon destroyed by rain or other watering. *Hugh Dixon, Elizabeth and Park Streets, Sydney, N.S.W.*

BERBERIS VULGARIS.

Your issue of September 11 last, which has just come to hand, contains a paragraph on the subject of Barberry and mildew on Wheat. It seems that in consequence, as it is supposed, of the common Barberry serving as the host-plant of the mildew of corn (*Puccinia graminis*), the Royal Swedish Agricultural Academy in Stockholm, and other authorities, have requested the railway directors in Sweden to grub up all the Barberry bushes within a certain distance of corn-fields. Nurserymen, too, are told to notify in their catalogues that *Berberis vulgaris* should not be planted in the vicinity of arable land. Now, the question arises whether the mildew found on Wheat is the same as the mildew to which the Barberry is subject? This is a matter which very much concerns many districts of New Zealand, as of late years the common Barberry has been planted by millions for hedges. It is admitted to be the best all-round hedge-plant that has been tried in northern districts. But if it is about to prove a nuisance to growers of Wheat, in fostering the development of an injurious parasite, then a great mistake has been made in planting so large an extent of Barberry. The possibility, however, is, [that the Swedish authorities have made a blunder in regard to the particular mildew. On referring to Stephens' *Book of the Farm*, I find the following statement about mildew on Wheat, a statement that upsets the common notion existing, that the mildew on Barberry is the same species:—"A notion prevails in England that the Barberry-bush (*Berberis vulgaris*) has the power of causing mildew in Wheat, probably from the well-known circumstance that the Barberry itself is very subject to mildew. But the mildew of Barberry is occasioned by the *Erysiphe berberidis*, whereas the mildew of Wheat arises from a *Puccinia*, and no possibility exists of transforming the one fungus into the other." We have thus two opposite teachings on the subject; and I should be glad to have the opinion of a competent expert as to who is correct—Mr. Stephens or the Swedish authorities; and especially as it is a matter in which the settlers of New Zealand are deeply interested. *William Morgan, Pukekohe, Auckland, New Zealand.* [It has been proved beyond dispute that the wheat-mildew is a stage of the *Æcidium* of the Barberry. Ed.]

THE FRUIT TRADE.*

I PURPOSE contrasting the fruit trade at the present day with what it was in the memory of many of us forty or fifty years ago. The chief cause that has led to its development has been railway and steamship communication. Fifty years ago the only supply was home grown, and of limited extent, the carriage from a distance to any of the local centres being difficult and expensive. The importation of foreign fruit, with the exception of Oranges and Nuts, was also on a small scale, irregular and uncertain. Occasionally, a few hundred barrels were sent from America in sailing-vessels by private individuals, and the trade in fresh produce, with the exception of a few Pears grown in Normandy and Brittany, was exceedingly small. The prices that had to be paid for fruit put it out of the reach of all but the well-to-do, except in the months of June, July, August, and September, when our home-fruits were found in all the markets in the immediate vicinity of the centres of production. I am quite safe in saying that during eight months of the year fruit to the multitude was practically an unattainable luxury, except when Oranges happened to be plentiful. The districts whence Oranges came to this

* Paper read by Mr. M. J. Garcia before the Horticultural Club, on Tuesday, December 14.

market were St. Michaels and Lisbon. They were sent in sailing ships, which were at the mercy of the winds, and it was no uncommon occurrence for the London market to be without Oranges for two or three weeks. I can well remember often seeing a fleet of ten or twelve sailing-vessels moored outside the wharf at London Bridge. Since that time the south of Spain has taken to growing Oranges, and we can call to mind the first few boxes of Valentias that arrived in Covent Garden Market. They were packed and owned by Robt. McAndrew and Co., who were then the great people in the St. Michaels' trade. In the first season certainly not more than 200 cases came to Great Britain, and in contrast with this, I may mention that last year the growth in the province of Valencia alone exceeded $3\frac{1}{2}$ million cases. The cultivation has increased to such an extent that a box of oranges can now be bought in the months of November, December, and January, at a price not exceeding 6s. f.o.b. Valencia, and throughout the season they are being sold here in Great Britain at as low a price as in the towns of Spain where they are produced. Oranges are now being grown in a new district, the province of Murcia; they promise to surpass in quantity, as they certainly do in quality, those of the province of Valencia. The Canaries also are in the field, and whereas six or seven years ago a supply of 200 or 300 boxes during the season was all that was produced, I hear on good authority that last year 5000 boxes were shipped, and that this year the output is more than double. These Oranges, which are of exceptional quality, will have to compete with those from Jamaica, Florida, and California. Florida Oranges occupy a pre-eminent position both in America and here. The frost some seven years ago nearly killed all the trees, and this will be the first season that there has been any crop to speak of. As regards California, the fruit is cultivated there with the greatest care under the most favourable conditions, and it is only a question of time for it to supplant all the rest grown in America. St. Michaels' Oranges, on the other hand, have deteriorated, so much so, that all the trees have been cut down and Pineapples planted instead. Palestine and Mexico are also now in the field with Oranges, and it is probable that the growth in Jaffa will attain such large proportions as to form a serious opposition to the best fruit that come from either America or Spain. Efforts have been made to introduce Jamaican fruit, but up to the present, with very disastrous results, the loss of one company alone being at least £34,000. The money, however, has not been thrown away, as great experience has been gained, and hopes are yet entertained of the mother country being able to assist in the consumption of the fruit of one of her colonies that has suffered most severely through the cultivation of sugar not being remunerative. As regards Pines, they are in St. Michaels grown under glass, and are of unexceptional quality and size. The average weight is from 2 lb. to 8 lb. They are nearly all of the Smooth-leaved Cayenne variety, and I am quite within the mark when I state that there are brought to London each year between 400,000 and 500,000 Pines. These, on account of their size and quality, have entirely supplanted the English growth. Canada is fully alive to the consumption of foreign fruit in England, and the Canadian Government have organised a department for the development of the trade. Cool chambers have been fitted up in the regular steam-ship lines to London, Liverpool, Bristol, and Glasgow; and the consignments that have arrived this season lead us to hope, now that America is practically closed to British fruit, that we shall be able to assist Canada by being customers for all kinds of her produce. Turning now to—

ENGLISH FRUIT,

the production fifty years ago was very small, except in the months of June, July, August, and September. Hot-house Grapes commenced at about 30s. per lb., and the lowest price, unless in unusual circumstances, was 2s. per lb. The month of November brought us to the end of English hot-house Grapes, and I can well remember when my grandfather, who lived in the Poultry, in Cheapside, had an order for Grapes for the Lord Mayor's dinner, the only person that could supply them was Mr. Crawshaw, of Colney Hatch, and this gentleman used to allow 50 lb. to be cut specially for this purpose. I have myself sold common Lisbon black Grapes in March at 30s. a lb. The only others that were then obtainable were a few from Almeria, and of these the supply was limited, the average quantity being about 30,000 to 40,000 barrels, and the price 20s. to 60s. a barrel. At the present time the average supply of this one variety is about half a million barrels, and they realise from 8s. to 20s. The cultivation of Grapes and Tomatoes under glass is a matter that you are better acquainted with than I am; but if the amount of care given to this particular branch had been devoted to the growth of Apples and Pears in England. I cannot help thinking that the trade in the latter would be much more profitable than it is to-day. French fruit, with the exception of Pears, was almost unknown fifty years ago, but now the demand is so great, that the cultivation in the south, where Cherries and Green Gages are grown, has been increased solely on account of the consumption in Great Britain. The quantity consumed in Great Britain is extraordinary, and although prices may seem dear, the freight in France is so high as almost to preclude anyone, with the exception of the French railway companies, from making a profit. The French Government, which has the monopoly of the railway system, throws all sorts of obstacles in the way of the carriage of fruit by fast French trains; and although these are no quicker than our ordinary luggage trains, the freight is higher than any of our railway companies charge for conveyance of similar goods by express. If fruit that reaches us from the south of France is charged

at the rate of $1\frac{1}{4}$ d. to $1\frac{3}{4}$ d. per lb. Chiefly English capital is now used in the development of this trade, and the largest firm in France, when desirous of turning their business into a limited liability company, had to come to England to obtain the capital necessary. I have left to the last the consideration of the enormous strides made in the

AMERICAN APPLE TRADE.

The result to the farmers in America always depends on the crop we have in the United Kingdom, and every year they are as anxious to obtain information as to the outlook here as we are to learn of the prospects on the other side. The business, which commenced with the shipment of a few hundred barrels fifty years ago, has now assumed gigantic proportions. In 1880 there were about 1,250,000 barrels shipped from America; for the next eight years the number varied from 81,000 to 800,000; while in 1896, when the crop was beyond all precedent, over 3,000,000 barrels were sent to Great Britain. This season the crop in general is poor throughout America. In the States the carriage of fruit is evidently much less expensive than here. The bulk that is now arriving is being shipped 2000 miles west of New York, at a cost per barrel that certainly does not exceed 15s. to 16s., everything included. If England is to compete with foreign countries, she will have to adopt methods similar to those in use in the country which has made a specialty of the growth of produce for foreign markets. California has certainly set an example as regards trouble taken in the growth of fruit, and in the development of the trade, and there are one or two facts which have come to my knowledge from reliable people which I may venture to place before you. Fruit-growing in America is a very important business, and the Government spares no pains in acquiring all possible information on the subject, distributing it in pamphlet form broadcast to all those who are directly or indirectly interested in agriculture. Fruit trees in California, as well as throughout America, are planted at a distance of 24 feet apart, and it has been ascertained from many years' experience that the trees bear more fruit and of better quality in this way than if planted closer. Except during the first few years, no grass or other vegetation is allowed to grow between the trees, and all that Nature and science can do is brought to bear on their development. Some Californian gentlemen have devoted themselves to the culture of fruit in other countries, and one of the most influential has established himself in Cape Colony, 250,000 trees having been sent there four years ago, and this year some of the first produce will reach England. They have decided to send not only to their own, but also to the English markets, and they hope that in a few years, Pears, Plums, and Apples, equal to the best grown in California, will be shipped to arrive here during the months of April, May, and June. On one farm alone 90,000 fruit trees were planted last year.

I certainly think that, as regards the production of Apples in England, the nurserymen are to some extent to blame for advocating the growth of new sorts, for, as I have already said, the old kinds of good eating quality sell well, while, on the other hand, many of the new varieties are difficult to dispose of, and less profitable. The same system that exists in America should be followed here, namely, particular attention should be paid to the cultivation of well known varieties, so that dealers here will be able during the season to depend on a good supply of particular sorts, such as King of the Pippins, Blenheim's, Cox's Orange Pippin, and others equally appreciated by the British public. Although the production of English soft fruit has increased in proportion to the population, foreign has not caused it to depreciate in value, as thirty to forty years ago, Cherries, Plums, Currants, &c., in plentiful seasons were sold at lower prices than under similar conditions at the present day. Thirty-five years since Bigarreau Cherries were sold as low as 5s. to 7s. per bushel of 48 lb., a figure hardly ever experienced in the present day; while 2d. per lb. for Black Currants was considered a high price.

AMERICAN NOTES.

FERNS.

COMMERCIALLY Ferns are used as much in the United States as in any part of Europe; but "Fern-fanciers," or "cranks," as lovers of any special hobby are called in this country, are "few and far between." But in the markets Ferns are a prominent feature, being extensively used all over the States. Adiantum Farleyense is highly thought of, and is grown in astonishingly large quantities. The late firm of Pitcher & Manda alone had nine houses entirely devoted to them, containing from 14,000 to 15,000 plants, in sizes from 2 inch or thumbs, up to 12-inch pans, forming a display of much beauty, and one not to be soon forgotten. The plants are sold to retailers all over the States, but chiefly in New York, Washington, Baltimore, and Boston—New York being by far the largest buyer. A. Farleyense is a surprisingly good shipper, better than the majority of plants. We once had occasion to despatch a case of

plants to Denver, Colorado, which was delayed on the road; and when it did finally reach its destination, the sole survivors were the A. Farleyense.

About the middle of the month of August, all double-crowned and unsaleable plants are divided, the fronds and roots being cut off, leaving the crown quite clean, and breaking or cutting them into pieces about the size of a large Pea, preserving a single eye, such always making the best plants. These are sown thickly on chopped peat, and covered lightly with the same. Within five weeks they are up 3 or more inches, and are ready for potting. This requires more care than at any other stage. The soil used consists of loam, leaf-mould, and sand, equal parts, and at the next shift they go into 3-inch pots, and this time rotten manure is mixed with the compost. After this potting, the hose is used in applying water, liquid cow-manure being applied by the same means by the aid of the "Kinney Pump."

The summer is the most trying time of the year for A. Farleyense on account of the dry heat, but this is overcome by throwing plenty of water about, especially overhead. English gardeners would, no doubt, consider this a very dangerous proceeding, but we find the plants grow luxuriantly under it. Plants started in August are ready for sale in 6-inch and 7-inch pots by November of the next year. For large specimens we put three or four 5-inch in a 12-inch pan. The prices are, 5-inch, 75 c., about 3s.; 6 inch, 125 c., or 5s.; and large 12-inch pans, 3 dols. 50 c., or 14s., there not being much sale for sizes above that. A. cuneatum is also extensively grown, some firms handling many thousands.

Next in importance are what are termed small, or, mixed Ferns," these being used for making up Fern dishes for table decoration, only the hardier varieties being used. Aspidium amabile, Lastrea opaca, L. lepidota, L. aristata var., Pteris chinensis palmata, P. Mayi, P. cretica albo lineata, and Blechnum occidentale being among the most used. These are raised in countless thousands, and sell for thirty to forty dollars per 1000, or three and four cents each. One Fern I must not leave out, and one that is grown largely, is what is known as the Boston Fern, which is the drooping variety of Nephrolepis cultrata, called here N. c. Bostoniensis, after the city of Boston, where it first came into prominence. Alfred T. Bunyard, Waverley, Mass., U.S.A.

SOCIETY.

SUNDERLAND AND DISTRICT GARDENERS' ASSOCIATION.

DECEMBER 20.—The above flourishing society held their seventh Annual Dinner at the Palatine Hotel, when upwards of sixty persons were present, the president, Councillor W. M. Koche, in the chair.

The membership, said Dr. Randell, increased yearly, and he noted the fulfilment of the hope expressed last year, that there should be an interchange of visits and papers between the Sunderland Society and that of Newcastle-on-Tyne; and he thought this might possibly be extended to other neighbouring towns.

Mr. T. W. Bolam, who has taken an active interest in the work of the society since its formation, has been unanimously elected chairman—six times out of the seven years of its existence.

CATALOGUES RECEIVED.

- KEYNES, WILLIAMS & Co., Salisbury—Cactus Dahlias.
- ROBT. VEITCH & SON, 54, High Street, Exeter—Flower and Vegetable Seeds.
- KENT & BRYDON, Darlington—Garden Seeds.
- G. P. DIXON & SONS, Hull—Garden Seeds.
- DICKSONS LTD., Chester—Seeds, &c.
- E. WEBB & SONS, Wordsley, Stourbridge—Seeds and Sundries.
- BROWN & WILSON, 10, Market Place, Manchester—Seeds.
- WM. SAMSON & Co., Kilmarnock—Seeds.
- JAS. DICKSON & SONS, 32, Hanover Street, Edinburgh—Seeds.
- LOUIS VAN HOUTTE PÈRE, Ghent, Belgium—Seeds, Begonias, Gloxinias, Caladiums, and other Plants.
- WM. PAUL & SONS, Waltham Cross, Herts—Seeds and Bulbs for Spring Planting, &c.
- S. F. OSSETT, The Nurseries, Ossett, Yorks—Chrysanthemums.
- JOHN LAING & SONS, Stanstead Nurseries, Forest Hill, London, S.E.—Vegetable and Flower Seeds, including Begonia Novelties and Sundries.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named: and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending January 1, is furnished from the Meteorological Office:—

"The weather was very unsettled, with frequent rain in nearly all parts of the Kingdom. Over Scotland and in most of the western districts the rainfall was very heavy. Thunder and lightning were experienced at some of the western stations on Thursday.

"The temperature was much above the mean, the excess ranging from 4° in 'Ireland, N. and the Channel Islands,' to 6° in 'Scotland, W.,' and in almost all the English districts. The highest of the maxima were registered at the commencement of the week in the western and northern districts, and on December 29 at most of the English stations they ranged from 60° in 'England, N.W. (at Llandudno), and 58° in 'Ireland, S.,' to 54° in 'Scotland, N. and W., Ireland, N.,' and several parts of England. The lowest of the minima, were recorded on December 26 in England, but on rather irregular dates in Ireland and Scotland; they varied from 22° in 'England, E.,' 23° in the 'Midland Counties and England, S.,' and 24° in 'England, N.E. and S.W.,' to 32° in 'Scotland, N.,' and to 36° in the 'Channel Islands.'

"The rainfall was less than the mean in 'England, N.E.,' and only just equal to it in 'England, E.;' in all other districts, however, there was an excess, that in 'Scotland, Ireland, the S.W. and S. of England, and the Channel Islands' being very great. The largest amounts registered at any of the individual stations were 6.0 inches at Killarney, 5.48 inches at Glenlee, 5.18 inches at Fort William, 4.36 inches at Landale, and 4.08 inches at Valencia.

"The bright sunshine was less than the normal over the Kingdom as a whole, but slightly exceeded it in 'Ireland, N. and England, N.W.' The percentage of the possible duration ranged from 22 in 'Ireland, S. and the Channel Islands,' to 7 in 'England, S.,' 6 in 'Scotland, E.,' and 4 in 'Scotland, N.'"

GARDENING APPOINTMENTS.

MR. GEO. STEWART, for the last three years Foreman in the Gardens, Alloa House, Alloa, N.B., as Gardener to Capt. W. H. FIFE, Langton Hall, Northallerton, Yorkshire.

MR. GEORGE MURRAY, for the last fifteen years Gardener to F. H. BOOTH, Esq., to P. R. WAND, Esq., 14, Springbank, Manningham, Bradford.

MR. LEWIS CHASTNEY, late Foreman at Shotesham Park Gardens, Norfolk, as Gardener to Mrs. A. A. HARRISON, The Shrubbery, Southtown, Great Yarmouth.

NOTICES TO CORRESPONDENTS.

ARUM LILIES DISFIGURED: *Unadorned.* The injury is due to some local circumstance in the cultivation. There is no fungus or other disease. In such a warm atmosphere, similar effects may follow an exceeding fluctuating temperature, or cutting-draught. Fumes from the stovehold may be suspected.

CATLEYAS: *Veritas.* In Cattleyas the flower-sheath, with, of course, a flower-spike enveloped in it, rises from the top of the pseudo-bulb or club-like stem. A flower-spike may contain from eight to thirty flowers. If new arrivals possess immature growths (pseudo-bulbs) or flower-sheaths, made perhaps during transit, these may remain if not injured.

DENDROBIUMS: *Veritas.* Most of the species, being natives of the tropics, would not succeed in the Cattleya-house all the year round, and nearly all of them would require a greater degree of heat in their growing period, and whilst maturing their growths. *D. nobile*, *D. bigibbum*, *D. superbiens*, *D. Goldiei*, and *D. Phalenopsis*, and most of the Australian species will succeed under moderately warm treatment. *D. speciosum* and *D. s. Hilli* succeed under a like kind of cultivation.

ENGAGEMENT: *A. F.* If you possess a written engagement you may be able to obtain compensation; and failing this, you might get a County Court judgment in your favour for one month's wages and perquisites, and travelling expenses. Why not consult a lawyer, it might be cheaper in the end.

FIG-TREE: *D. J.* All fruits larger than small Peas should have been taken off, as they will come to nothing. You may begin to force the tree now or later, beginning very gradually to increase the warmth. Study past and future Calendars in this journal.

GREEN PEAS: *X.* Probably the failure arose from the bladder or cover not being sufficiently tight, and the bottles not being sufficiently filled so as to leave as little interspace as possible between the Peas and the cork.

HOME-MADE GRAFTING-WAX: *Flammula.* Take 1 lb. of beeswax, dissolve it in a glue-pot, and gradually add mutton-suet or tallow, till it loses as much of its stickiness as will permit it to be readily manipulated, and yet get fairly hard on drying. When using wax of this kind, it should be kept in a plastic state by means of a small spirit-lamp placed beneath the vessel containing it. It is handier than clay, a mere coat of it being as effective in excluding moisture and air as a large quantity of the former.

HYGROMETER: *C. Whitfield King.*—The hygrometer mentioned on p. 430, which is in use at Burford, consists of two fine carefully graduated tubes, containing mercury, the bulb of one being covered with thin muslin, and round the neck the muslin should be twisted loosely, or tied in a loose knot, a conducting thread of lamp-wick, or some similar material, which passes into a vessel containing water placed at about 3 inches below the bulb, and a little on one side of it, so that evaporation from the water may not affect the reading of the dry bulb by its too close proximity. The hygrometer just described is less complicated and expensive than those in which the dew-point is ascertained by the use of ether, &c. The instrument is useful in all the Orchid-houses, especially during the winter months and dull damp weather. When the readings on the scales of the two thermometers are equal, that is the saturation point. During the middle hours of the day, from 6° to 8° of evaporation should be allowed. At other times, about 2° for the *Phalenopsis*-house, and 1° for the cool-house, saturation point never being maintained. *W. H. W.*

NAMES OF FRUITS: *C. P.* Apple Dumelow's Seedling (Wellington), one of the very best long-keeping kitchen varieties.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*W. T.* 1, *Retinospora pisifera*; 2, probably a form of *Cupressus Lawsoni*; 3, *Cupressus nootkatensis*; 4, *Thuja occidentalis*, var.; 5 and 6, variety of *Thuja orientalis*; 7, *Retinospora pisifera*; 8, *Juniperus* not recognised; 9, *Juniperus sinensis*; 10, *Crataegus Pyracantha*.—*H. P.* Iris foetidissima, common as a wild plant in some places in Great Britain.—*L. B.* The Orchid is *Laelia autumnalis*;

the other plant *Cestrum* (*Habrothamnus*) *fasciculatum*.—*G. H. W. L.* 1, *Aralia Guilfoylei*; 2, *Begonia nitida rosea*; 3, *Croton angustifolius*; 4, *Croton variegatus*; 5, *Croton irregularis*; 6, *Croton Evansianus*.—*J. P. K.* *Maxillaria punctata*.—*W. O. W.* 1, *Pteris serrulata*, crested-form; 2, *Garrya elliptica*; 3, *Cestrum fasciculatum*; 4, *Phyllocactus* sp.

SHRUBS AND TREES AND RABBITS: *A. N. C.* We know of but few plants that rabbits will not bark when driven to do so by hunger. The Yew, Savin, Red Cedar, *Thuja borealis*, Butchers' Broom, Ivy, Periwinkle, *Berberis aquifolia*, Gorse, Privet, *Garrya elliptica* they will rarely touch.

STOCK FOR CLEMATIS GRAFTS: *Flammula.* The stock commonly employed is *C. vitalba* (Traveler's Joy), the seed of which can be purchased at a low rate, or gathered from the hedgerows in southern shires, where the soil is chalky. Clay or grafting-wax are used, and but little of either, the point of union coming below the ground-level.

VANDA MASSAIANA: *H. J. P., Poggio Gherardo.* We thank you for the drawing, and also for your interesting letter on the subject. We have no knowledge of "Vanda Massaiana," and we can find no record of it. The drawing gives a very fair representation of *Staurosis lissocylindroides* (*Vanda Batemanni*); but if your plant is different from that species in the habit of its growth, it may not be that species. The peculiarity of the basal flower being different in colour, and in other particulars, is a common feature in some of the species of *Staurosis*, *Arachnanthe*, *Grammatophyllum*, &c. Indeed, even in some of the small-growing Orchids, usually designated "botanical," such as *Bulbophyllum hirtum*, *B. auricomum*, &c., the same peculiarity is seen. We will endeavour to get information about *Vanda Massaiana*, and communicate.

VIOLET PLANTS IN FRAME DAMPING OFF: *D. J.* Your plants damp off because the frame is insufficiently ventilated. The sea air has nothing to do with it, and is favourable rather than otherwise, as being milder than far inland, rendering covering up the frame with litter, &c., not so necessary during the winter, and the opening of the frame at the back in order to afford air from 10 A.M. till 2 or 3 P.M. safe almost daily. Give as much air as possible with safety; apply no artificial heat, but keep out frost by means of thick linings of straw litter built up to the top of the frame, and always keep these at that height; press the soil firmly round each plant, cover the soil with a layer of cocoa-nut fibre refuse, or half decayed leaves; and if the tops of the plants are further than 6 inches from the lights sink the frame, if you can, in order to bring them up to that distance from the glass.

WASH FOR THE STEMS OF FRUIT TREES: *J. B. & Sons.* Clay, cow-dung, and lime, mixed with soapsuds to the consistency of thick paint; when well mixed add half-pint of spirits of tar to 3 gal. Let the stuff be applied twice during the winter. It need not be applied higher up the stem than 4 feet, except in districts where the snowfall is usually heavy.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,

MORE THAN DOUBLED, and that it continues to increase weekly.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, and ALL CLASSES OF GARDENERS and GARDEN-LOVERS at home, that it has a specially large FOREIGN and COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

(For Markets see p. xiii.)

THE

Gardeners' Chronicle.

SATURDAY, JANUARY 15, 1898.

A LITTLE CORNISH GARDEN.

THE garden whose chronicle I both keep and partially make is no realisation of Baconian ideal. Its "contents" fall very, very far short of "Thirty acres of ground. . . . Foure acres being assigned to the greene, six to the heath, foure and foure to either side, and twelve to the maine garden." Quite otherwise, my little plot is materially but a small piece of ground enclosed by low walls on all sides; and, when I took possession of it two years ago, a more hopeless, irregular, poverty-struck patch, covered as it was with bindweed, couch-grass and other weeds, it would tax the utmost patience and ingenuity to discover.

My predecessor took no interest in gardening, and considered the possibilities of the situation not such as to merit much expenditure of labour or money. And truly it did look a hopeless task to extract much beauty from it. But I thought of Virgil's contented old Corycian, who acquired possession of a few acres of waste land which was not worth ploughing, of no value for pasturage, and quite useless for vine-growing; yet by steady perseverance and hopefulness this genuine old gardener made things grow everywhere, and was enabled to cover his supper-table with dainties of his own growing. He was always able to pick the earliest rose in spring and the first autumn fruit; and, even when gloomy winter cracked the ground with hard frosts, he still had flowers in sheltered nooks with which to cheer himself and nourish his bees.

Unfortunately, I had come into a few acres of neglected land, and I saw that, if I were to maintain my interest in gardening, and show myself to be a worthy descendant of the veteran of the Georgics, I must make the best of what I had until such time as Fate should give me the garden which my mind has ever imaged.

So, first of all, I thoroughly broke up the ground, cleaned it of weeds as far as possible, and incorporated a heavy dressing of manure. I saw that it was useless to hope that the weeds were conquered, and so I decided to grow nothing for a season but vegetable crops, which would necessitate the ground being dug and cleaned a few more times. I took time by the forelock, however, and planted a number of pyramidal fruit-trees in the autumn. These have now developed, and will, I hope, yield me a good crop next year. Continual forking, digging, manuring, and weeding, have now made the soil such as will produce fruit and flowers. Paths have been made, and borders have naturally been produced; seeds have been

sown, and bulbs planted; a small greenhouse and frame have been built, and the little waste-plot looks like an adjunct to a human dwelling.

As the garden is entirely overlooked by every passing train—the railway arching over the valley on whose slope my garden lies—I have planted some standard fruit and other trees to cut off that view as far as may be. You see, I am English, and like to ply my hobby in privacy. For I hold that a garden is a place whither one should be able to retire from the *profanum vulgus*—like a private study, like even silence itself, in that we may thence defy the outside world. This, then, is an aim which the true gardener should bear ever in mind, for no garden can afford a substitute for the beauties of unsullied Nature. The grandeur and glory of the forest the hill and the plain are quite other than anything which the garden can give. This is as certain as the truth that no library can serve as a substitute for the world of men.

The profound emotion that we term melancholy, which grand scenery produces, is absent from the garden effect. Gardening, on the other hand, is calculated to breed in its devotees a feeling of quiet content, mainly—we may suppose—because it is constantly telling the gardener of his power in obtaining desired and beautiful results. Yet, full as much as angling, gardening is truly "the contemplative man's recreation." Raising giant flowers for competition at flower-shows is scarcely the kind of thing I mean. The gardening which attracts me is on a footing with old Isaac Walton's fishing. I like to be my own gardener, and I take an interest in my plants as individual living things, as well as bits of beautiful colour and form. I like to see a plant grow and develop, to study its distinctive features and their causes, and to read about it and so learn what others have observed. A small, convenient and healthy house, a large and well-situated garden, a good library gradually accumulated, a small competency—and what more in the way of physical possessions can the contemplative man require?

Hardy plants alone possess much interest for me. Plants in pots savour too much of the pet-bird idea. Keeping a loose domestic dog or cat is one thing, but keeping a lark or even a canary is quite another. Besides, I like my plants to establish relations with definite spots in the garden. It is pleasant to feel that the fading Crocuses will come again in the same spot next year; that the Snowdrops may be expected to brighten the base of the Pear-tree each spring with increasing effect. Therefore I have planted my garden with Roses in great variety of the best kinds (not Hybrid Perpetuals and Teas only, but also the sweet old summer Roses, and many of the single species such as alpina, acicularis and bracteata), with all kinds of Daffodils, Narcissi, Irises, Anemones, Primulas, Cyclamens, Crocuses, Tulips, Gladiolus, Snowdrops, Aconites, Colchicums, Columbines, Campanulas, and the like. I hope to have flowers out-of-doors the year through, except perhaps in the very heart of winter. Yet I am inclined to think that December and January are among the gardener's happiest months. It is then that he is enabled to practice "*L'Art de se rendre heureux par les Songes*," as the title of an old book runs. For, after all, however successful may be our gardening, realisation is realisation, and can only give the joys which appertain to itself; whereas, in the apparently dull months of winter, we have all the pleasures which expectation and the conception of infinite possibilities

can give. Although, when I drag my friend into my garden, he reports that he can see little but bare earth, and leafless trees and shrubs, I can scarcely understand it, for I can see here a mass of glowing Escholtzia in every shade of orange, white, and yellow, there a clump of Daffodils in bloom, here a bed of Tulips, there a galaxy of beautiful Roses. I see all the flowers of every month, and they are almost as real to me as they will be when they are visible to all. *Harry Roberts.*

(To be continued.)

ORCHID NOTES AND GLEANINGS.

LÆLIO-CATTLEYA × LUCY INGRAM
(*purpurata* ♀, *Perrini* ♂).

EQUAL in beauty to a good *Lælia purpurata*, and possessing the advantage of flowering in winter, this fine hybrid gives a good example of the useful work done by the raiser, Mr. T. W. Bond, gardener to C. L. N. Ingram, Esq., Elstead House, Godalming, who has succeeded in obtaining a large number of fine *Lælio-Cattleyas* and other showy hybrids. It was first shown at the meeting of the Royal Horticultural Society on January 12, 1897, receiving an Award of Merit. The plant is again in bloom, and shows increased vigour. Another plant has also bloomed, which is larger than the original in size, and slightly darker in colour. The flower measures 7 inches across the petals, and therefore equals a good *L. purpurata*. It also approaches that species in the shape of the bloom, though the unmistakable trait of *L. Perrini*, as seen in the peculiar form of the front part of the lip, is very evident. The sepals and petals are white, in the lighter variety slightly, and in the darker more decidedly, tinged with lilac. The base of the lip in both cases is blush-white, veined with purple in the interior; the front and edges of the side-lobes being of a rich violet-purple colour. *James O'Brien.*

LÆLIA AUTUMNALIS VARIETIES.

Flowers sent from various correspondents prove the extraordinary variation which exists amongst plants of this beautiful winter-flowering species. There exist undoubtedly two or three distinct types, each with its set of varieties, which are derived from different localities in Mexico. First, there is the oldest type, which was quite eclipsed by the larger and more richly-coloured *L. autumnalis atrorubens*, introduced for the first time by Messrs. Backhouse of York in 1879; and later by Messrs. F. Sander & Co. This type has the richer colours, and shows the least variation. Some fine flowers of *L. a. atrorubens* have been received from Mr. J. Cypher of Cheltenham, and the only apparent variation, a blush-white form of it from Mrs. Ida Brandt of Zurich. The third distinct type is tolerably abundant in gardens, and most of the white and blush-white flowered forms belong to this type, the deeper-coloured ones not being comparable to *L. a. atrorubens*, although they are useful as flowering in the winter. The best pure white form comes from G. F. Moore, Esq., Chardwar, Bourton-on-the-Water. The flower is likewise larger and better than other white varieties which we have observed. Two distinct forms of this class are sent by Mr. W. Gould, Rose Bank, Hayfield, near Stockport. Both belong to the narrow-petalled class, the one with a white base to the lip and other segments, the outer halves of which are rose-coloured; the other with clear white lip, the front lobe of which and the sepals and petals are bright light-purple. Another flower sent by Captain Holford, in its broad segments and broad front lobe to the lip, very closely resembles the fine *L. a. venusta* of Messrs. Backhouse.

LÆLIA ANCEPS PROTHEROEANA.

A few years ago there appeared a very brilliantly-coloured form of *Lælia anceps*, which was named in honour of Mr. W. H. Protheroe, of the well-known firm of auctioneers of Cheapside. Its flowers are of

fine size, of much substance, and of a warm, glowing colour. A fine flower of it is sent by James Davidson, Esq., Somerville, Dumfries. The sepals and petals are of a bright purplish-rose colour; the broad labellum yellow at the base, with dark purple lines running on each side of the orange-coloured central keels. The front lobe of the lip and the conspicuous sides of the basal lobes are of a brilliant ruby-crimson, which appears all the brighter by contrast with the small white area in front of the crest.

CALANTHE X VEITCHI SPLENDENS AND OTHER PLANTS.

A grand inflorescence of over forty brilliant carmine-rose flowers is sent by Mr. A. Chapman, gr. to Captain Holford, Westonbirt, Tetbury, and it is specially noteworthy on account of the history attached to it. The plant was selected from some unflowered seedlings which the late Mr. James Veitch let the late Robert Stayner Holford have many years ago, which have supplied the stock from which the fine specimens seen every winter at Westonbirt have been raised. Two fine varieties of *Lælia anceps* and *L. autumnalis*, a handsome form of *Dendrobium Phalaenopsis delicatum*, and a superb large white *Odontoglossum crispum* are also included.

ORCHID PRICES.

According to the *Semaine Horticole*, the highest price for an *Odontoglossum* yet given is 12,000 francs (£480), for *Odontoglossum crispum* var. *Luciani*; 7500 francs (£300) for *O. crispum* var. *Lindeni*; 5000 francs (£200) for *O. crispum* *Moortebeekense*.

WARSEWICZELLA COCHLEARIS, Rehb. f., *Cogniaux, Dict. Icon. Orchid.*, t. 1.

COLCHICUM CILICICUM.

According to Boissier this is synonymous with *C. byzantinum*; but Mr. Siehe, at Mersina, who found it in large quantities, writes to me, that it is quite a different species. The colour of the flowers is a rich rose, somewhat tessellate. Mr. Siehe writes, that strong bulbs produce as many as twenty-five flowers, which are of the largest and broadest of the whole genus; but the flowers may remain in a fresh state without water for a period of five or six days—so this species will be one of the best for decorative purposes. Our illustration (fig. 12) was taken from a photograph sent by Mr. Siehe; it shows a medium-sized plant of half the natural size. *U. Dammer.*

PLANTS AT LA MORTOLA.

COMMENDATORE HANBURY sends a list of over 400 species of plants in flower at La Mortola in the open border on New Year's Day. He adds that thus far there has been no frost, but the nights are cold, and large quantities of snow are visible on the maritime Alps.

The past year has been a very bad one for the peasants and small cultivators in this district; the

Olive crop was a total failure, and although the vintage was good near the coast, the ravages of the phylloxera were disastrous in the higher lands.

The price of Lemons is so low that their culture is unremunerative; while the new industry of flower-growing seems in great danger of being overdone, those engaged in it complaining loudly of not being able to effect sales, till colder weather coupled with the increased demand for Christmas improved the situation.

Lastly, the Government has chosen this particularly unpropitious moment for increasing in the most ruthless and arbitrary manner the valuations on which the income-tax (*ricchezza mobile*) is based, until many hard-working and honest people are almost in despair.

NOVELTIES OF 1897.

(Concluded from p. 20.)

STOVE AND GREENHOUSE PLANTS.—Looking back to the time when the greater part of the plant-houses in gardens were filled with specimen Heaths, Epacris, Boronias, &c., so far as the cold-houses were concerned, and with ponderous Allamandas, Stephanotis, Clerodendrons, and such-like subjects in the warmer-houses, we see what great changes the altered habits of their owners, brought about by the altered con-

ditions of social life, have wrought. Formerly the plant-houses were expected to give pleasure only when their owners were staying at their country-houses. Now the facilities for quick delivery of packages makes their produce available whether the owners be in the neighbourhood or not, and there is an increasing desire to get full value out of the gardens. Con-

the past year, the continuation of the winter-flowering Begonias of the Mrs. Heal class have resulted in several charming, profusely-flowering, carmine-rose coloured novelties, of which the two best are Begonia Julius, which is quite a new departure in the winter-flowering section, having very double carmine-rose flowers, which are very persistent, each flower lasting

a very dark crimson; Ignacite, a splendid white, veined with rose colour; Topaz, white, striped with rosy-scarlet; and Francisca, orange-scarlet, with white eye. In the Chelsea strain of Streptocarpus, found so useful in gardens, is continued, improvement made, and a new set of hybrids of great beauty has been produced, and named Streptocarpus achimeniflora. Caladiums,

FIG. 12.—COLCHICUM CILICIMUM: FLOWERS DEEP ROSE-COLOURED. (SEE P. 34.)

sequently, in place of the large specimens formerly grown, quantities of plants useful for decoration in the house, or for supplying cut flowers, in a very great measure take their places. Hence, the nurseryman has to work up novelties which can be grown easily and in quantity, and which form neat and floriferous plants.

Messrs. Jas. Veitch & Sons have worked carefully on many suitable subjects, and of their novelties of

quite three weeks before fading; and the equally handsome B. Winter Cheer, shown at the meeting of the Royal Horticultural Society, held on December 14. Both these are so floriferous that they show more flowers than leaves when well grown. Of the splendid strain of Hippeastrums (Amaryllis) evolved by Messrs. Veitch, many new ones have appeared, those certificated being Pera, a fine flower of a reddish-scarlet tint, mottled, and banded with white; Thunberg,

especially with a view to secure dwarf compact habit, have also been worked, and the best novelties out of them are C. Lady Stafford Northcote, with silvery-white foliage; C. Mrs. McLeod, bright salmon-red; and C. Silver Queen. Other fine novelties shown by Messrs. Veitch are Nepenthes × Tiveyi, one of the finest and most distinct. Rhododendron superbissimum, the finest pure white of the Himalayan section; Phyllocactus Adonis and P. Syrenus, both

fine, and of a new tint of rose and salmon-rose; *Marattia Burkei*, a noble Fern; and in this section may be mentioned *Disporum Leschenaultianum variegatum*, and the elegant *Apera arundinacea*, both of which, although tolerably hardy, will be more useful grown as decorative plants under glass, and new for that purpose.

Messrs. F. Sander & Co., St. Albans, in *Petunia* Mrs. Fred Sander, staged at the Temple Show, had the very finest novelty of its class, the very double flowers being abundantly produced, prettily fringed, and of a delicate rose-pink and white colour. Nothing like it has been seen, and as a plant for general decorative purposes, it will be largely grown. Their *Petunia* Mrs. John Jefferies, and others of the same strain, are also quite novel. The *Coleus*, too, are favourites at St. Albans; and among the new and good are *C. Black-bedder*, *C. Mrs. Fred Sander Improved*, *C. Gaiety*, and *C. tricolor undulata*. Of *Caladiums*, the best are *C. albanense*, *C. speciosum*, and *C. venosum*; and of other new or rare plants at St. Albans may be mentioned, *Anthurium bogotense*, *Philodendron imperiale* *Laucheana*, *Davallia hirta plumosa*, *Arisæma Bakeriana*, *Canna Sander's* new variegated, *Mapania pandanifolia*, *Begonia peristegia*, and the fine set of *Palms* exhibited at the *Hamburgh Show*—*Cyphokentia Kirsteniana*, *Licuala Jeavenceyi*, *L. Leopoldi*, *Areca Ilsemanni*, *Ptycho-areca Warteliana*, *Dæmonorops Julesiana*, *Kentia Sanderiana*, and *Thrinax javanense*.

Of novelties noted before, but only just now getting properly appreciated, should be mentioned *Dracæna Godseffiana*, one of the finest decorative plants of our times, its durable, entire, bright-green foliage vividly marked with clear yellow, making it effective either as a large or small specimen, and its cut sprays for florists' purposes are greatly in demand already.

Messrs. B. S. Williams & Son, Holloway, sent out in 1897 the new form of variegated *Agapanthus*—*A. umbellatus aureo-striatus*; several new *Amaryllis*, particularly fine being *Holloway Belle*, *The Hon. Maurice Gifford*, and *Lord Brassey*; *Canna* (flowering) *Antoine Vallot*, *Crimson Banner*, *Eldorado*, and *Prince of Orange*; two very fine *Cliveias*, *Queen Victoria* and *Holloway Belle*; *Impatiens Magenta* *Queen* and *Salmon Queen*; *Croton Johannis gracilis*, one of the most elegant of *Codæums*; and a fine set of eight new and distinct *Gloxinias*.

Among other worthy novelties exhibited and certificated during 1897, may be mentioned the fine set of *Amaryllis* exhibited by Captain Holford, of *Westonbirt* (gr., Mr. Chapman), at the *Royal Horticultural Society*, on April 13, and of which *Chimborazo*, the *Czar*, and *Duke of York*, all of intensely rich colour, secured *Awards of Merit*; the useful and pretty late-flowering *Nerines*, raised by H. J. Elwes, Esq., out of whose effective group shown at the *Royal Horticultural Society*, on October 26, seven received awards. The pretty *Anemia rotundifolia*, of Mr. Wm. Bull; *Sonerila Lady Burton*, and *S. Leopold II.*, of Sir Trevor Lawrence; *Lomaria ciliata grandis*, and *L. c. Major*, of Mr. H. B. May; *Richardia Pentlandi maculata*, of Messrs. John Laing & Son; and the fine *Bougainvillea Cypheri*, for which Mr. John Cypher, of Cheltenham, secured the gold medal at the last *Shrewsbury show* as the best plant exhibited.

Begonias are justly as great favourites as ever, though there is increasing difficulty in finding distinct novelties in the older classes of the tuberous-rooted kinds. Early though it was for *Begonias*, the last great Temple Show brought forth a grand display of them. Selections made in the fine group shown by Messrs. John Laing & Son were *Duchess of Marlborough*, a fine double, rose-pink; *Lady Hamilton*, single white; *Clio* and *Diamond Jubilee*, double yellow; and *Doctor Jim*, double red. In the stand shown by Mr. J. R. Box, of West Wickham and Croydon, fine things were *Queen of Wurtemberg*, double yellow; and *Queen of Queens*, apricot-yellow. In Mr. Cannell's (of Swanley) group, the best were Mrs. W. B. Milner, crimson; Mrs. Leopold de Rothschild, and Lord Sherborne, grand flowers.

Mr. H. J. Jones displayed his fine improvements well, and among them were noted B. H. J. Jones, one of the most brilliant scarlets; *La France*, pink and primrose yellow. In Mr. Thos. Ware's group, very fine were *Jubilee Beauty*, carmine-scarlet; *Samuel Pope*, and *Jubilee Queen*. Mr. W. Baylor Hartland, of Cork, has also given much attention to the tuberous *Begonia*, and his B. Mrs. W. B. Hartland is, perhaps, the finest double white.

Messrs. Sutton & Sons, of Reading, also do good work in the perfecting of their fine strain of dwarf, floriferous, and showy, fibrous-rooted *Begonias*, in which they have attained something like perfection, as demonstrated by the fine display they made with them at the Temple Show. Sutton's *Snowflake*, *Crimson Gem*, and *Coral Gem* may be taken as good examples of a race of plants good for all purposes, such as bedding, basket-work, conservatory, and indoor decoration, and for cutting. In *Gloxinias*, too, the Sutton strain still preserve their high character; and it is generally admitted that it is infinitely better and more satisfactory to grow from such seeds than to trouble to propagate by old tubers or leaves, as finer flowers are secured without the risk of disease.

Chrysanthemums have been so well and numerous recruited during the year as to demand a special notice. Suffice it therefore for the present purposes to say that among the foremost of the introducers of fine novelties are Messrs. H. J. Jones, Owen, Wells, Godfrey, Cannell & Sons, all of whose productions, together with those of others, have frequently been remarked in the columns of the *Gardeners' Chronicle* during the past year.

Hardy Plants.—Of these during 1897 Messrs. Jas. Veitch & Sons have received awards for *Escallonia* × *Langleyensis*, *Celmisia Monroei*, *Hibiscus cœlestis*, *H. totus alba*, *Veronica La Seduisante*, *V. Silver Queen*, *Libocedrus decurrens aurea*, and *Cedrus atlantica aurea*, the last-named not new, but yet very rarely seen in gardens.

The *Narcissus*, which, together with the *Iris*, may be regarded as on a par with the *Orchids* among bulbous plants, have for chief novelties the handsome *N. Ellen Willmot*, *Lettice Harmer*, *Snowdrop*, and *Southern Star*, of the Rev. G. H. Engleheart; and the *N. Beauty*, *Odorus*, *Hermione*, *Samson*, *Victoria*, and *Snowflake* of Messrs. Barr & Son.

Martin Smith Esq., Mr. Jas. Douglas, Mr. C. Turner and others, have produced novelties in *Carnations*.

Messrs. Kelway & Son, of Langport, still pursue the raising of the *Gladiolus*, *Iris*, *Amaryllis*, *Gaillardias*, *Pyrethrums*, *Delphiniums*, *Pæonies*, and other flowers for which they are noted, with success.

Messrs. Wallace & Co., of Colchester, have again by their good culture brought under notice the beautiful race of *Calochortus*, or *Mariposa Lily*, and they have secured awards for three new or rare species during the year.

The *Dahlias*, *Roses*, and other great classes of florists' flowers, have been well recruited by those who make the culture of them a special feature, and generally speaking the year's work has been satisfactory.

Among the novelties or rare plants illustrated in the *Gardeners' Chronicle* in 1897 are—

Alberta magna, December 11, p. 411.

Apera arundinacea, October 23, p. 283.

Angelonia grandiflora alba, October 30, p. 307.

Violets, new types, April 17, p. 249.

TO FORCE TURNIPS.

Good Turnips can be obtained by forcing, providing the heat be moderate, and the plants are grown in a healthy atmosphere, free from rank steam. For years I deplored the scarcity of fresh sweet Turnips in March, April, and May. I am aware that from a late sowing in August good roots may be had through March, but as soon as new growth commences they lose quality.

To force Turnips successfully, no draught should be permitted, but more air is required than is usually given in the case of other vegetables, and ample moisture, with very little top-heat, for if the top growth be too much in advance of the root, they may "bolt." We rely largely upon fresh leaves wherewith to make the hotbed for our early Turnips, though they are slow in giving the necessary warmth; the leaves afford a genial moisture. The present is a good time to prepare for forcing, and about twelve or thirteen weeks will suffice to produce fine roots. Frames are preferable to pits or houses for forcing these roots, as the plants grown in frames are so much nearer the glass, and, consequently, the light. The plant does well in a fairly light compost, if it be made firm; and I find a liberal amount of wood-ashes much better than rich manure, which is best omitted.

Turnips can be grown in much less time than I have advised, but my remarks concern a full crop. Forced slowly, one can secure as good roots as those in the open garden, and of first-rate flavour. I used to get early roots of this vegetable without the aid of glass merely with leaves and mats, but they were later, and that was in a northern locality.

I think the *Extra Early Milan* type, of which there are two varieties, the red and the white, are far superior to the *Early Paris Market*. The first-named varieties are much flatter, and more precocious than any I know of, being quite ten days earlier, and less likely to run to seed during forcing. Of the two

varieties, I prefer the purple-topped, but, of course, neither is useful for keeping purposes. At least 6 inches of soil should be given the roots, and they should never lack moisture from the time the plants show above the soil. Early thinning is advisable, and the seeds should be sown thinly, as under glass every seed germinates. Plenty of ventilation in fine weather should be given, and it is far better to cover the glass at night in severe weather than give much added heat; 55° at night is ample, and 10° higher by day. In mild weather, give a little ventilation during the night. When growth is active, weak manure-water may be given; and should the plants not bulb quickly, it will be well to keep them a little cooler. *G. Wythes.*

WORM-EATING SLUGS.

JUDGING from the correspondence which has recently appeared in these columns, one would say that the worm-eating slugs still continue to receive their fair share of attention from those in whose

FIG. 14.—AULOPORNA HELICINUM.

Portion of the tongue, showing the teeth. Highly magnified.

way they come, but that, at the same time, there are still some points for one to learn with regard to their peculiar habits. It was apparently a notice which the Editor of the *Gardeners' Chronicle* kindly published, in the hope of helping the present writer in his work on these animals, which gave rise to the letters alluded to, and, under the circumstances, some observations which the latter may be able to offer upon points which have cropped up or upon the subject generally, may be found to be of interest.

As the bulk of correspondents to whom one is indebted for information and for specimens consists of horticulturists, it may be said that the slugs in question are known to a fair number of gardeners; but, on the other hand, it is impossible to disagree with Mr. M. Webster (*ante*, p. 314) when he says that the majority are unacquainted with them. The question of distribution, raised by the same correspondent, will come in more aptly when something has been said about the species occurring in the British Isles. The statement that Testacellæ, like other subterranean animals—earth-worms for instance—are sometimes to be found above-ground, can be endorsed by the writer, who has often found them under logs during early spring and autumn, and at other times on the surface of the soil in a hot-

house. It is hardly necessary to point out that it is Mr. S. H. Boyle himself (*ante*, p. 349) who is wrong as to the food of these creatures, the devouring of earth-worms by them having been recorded by many observers, from du Gué in 1740, onwards. The accounts given by a number of previous authors were discussed by the present writer in the light of some fresh experiments made by him, in the *Zoologist* for August, 1893. The most remarkable part of the performance is the way in which the "tongue" (radula or lingual ribbon), which is borne upon a spoon-shaped cartilage, is rapidly shot out from the mouth of the hungry slug; the "tongue" (fig. 5) bristles with many barbed

certainly than in the experiments, would continue to irritate the surface of the slug, seeking the groove above the slug's mouth—in some cases small worms actually manage to force their prostomia (noses) into the oral aperture—and would be caught in the grip of the radula as it was shot out, and held securely, the slug maintaining by its broadened body a firm hold on the walls of the burrow. This method of procedure would not, of course, prevent the Testacella from attempting to secure worms in the open, its stealthy movements not alarming the latter in any way; but it would not be so certain of a meal, as the chances of a successful hit with the radula are by no means so great." In the quotation, it is assumed that the worm is seized by the anterior end, at least when underground, and in spite of Mr. Parish's statement (*ante*, p. 404), one is still inclined to hold the opinion that this method is the one intended to be adopted, for the reasons given below, though when the animals are on the surface as hinted above, it probably is a case of seizing any possible part.

FIG. 13.—TESTACELLAS.

1, *T. haliotidea*; 2, *T. scutulum*; 3, *T. Maugei*; 4, a specimen of *T. scutulum* which has just seized a worm; 5, The "tongue" as shown in figure 4, but greatly enlarged.

"teeth" raking backwards, and its edges close inwards as it comes to its point of fullest extension, thus seizing anything that may be within its grasp (fig. 4), while the barbed "teeth" can pierce and hold any prey with which they may come into contact. In connection with "W. T.'s" letter (*ante*, p. 386) it may be pointed out that there is no "jaw" present in this or in any other genus belonging to the family Testacellidæ. In the paper referred to above, the matter of feeding is summed up as follows:—

"It will be seen that Testacella is particularly well adapted for catching its prey, should it meet them in the mouth or other portions of their tunnels. The slug on coming into contact with the head of an advancing earthworm, appearing above ground or what not, would contract, and shrinking back would entirely block the way with its now swollen body. The worm in endeavouring to proceed, with more

FIG. 15.—TESTACELLA MAUGEI.

Portion of the tongue, showing the teeth. Highly magnified

(1) The majority of observers mention the anterior end.

(2) In all experimental cases it was found that worms seized by the middle, escaped.

(3) With a large worm it would be difficult or even impossible for two thicknesses of worm to be swallowed at once.

(4) In the only case (and this in a tin box) where the writer found a slug which had seized a worm by the middle, the latter was eventually dropped even though held for more than twelve hours.

There are three species of Testacella which occur on these islands, one of which *T. maugei* mentioned by "W. T." (*ante*, p. 386) is easily distinguished by its comparatively large shell from the other two, *T. haliotidea* and *T. scutulum*, both of which are alluded to in the correspondence under the former name. Mr. M. Webster's description seems to fit *T. scutulum*, and while specimens received from Gledstone Hall belong to this species, those from Stourbridge (*ante*, p. 349) are *T. haliotidea*. It is only during the last few years that our naturalists have recognised as distinct, the two species with smaller and flatter shells, which differ very markedly internally, and can be distinguished in most cases without difficulty by their outward characteristics.

during the winter months, but in summer it prefers a more damp and shady position. At the present time the flower-buds are forming at the apex of the newly-made growths, and the plant should be well supplied with water until the flowers fade. The small leaves of this species must be guarded against red-spider. My practice is to take the plants down two or three times a week and hold them head downwards in tepid rain-water, then with finger and thumb gently wipe the under-sides of the foliage. When the plants have flowered, growth soon commences, and, if necessary, the plants may be repotted, but the roots must be disturbed as little as possible. The rooting material should consist chiefly of sphagnum-moss with a few pieces of fibrous peat, and below this good drainage. *Cypripedium Spicerianum* and *C. Charlesworthi* thrive well in a cool, shady corner of the intermediate house. Having flowered, the plants may be repotted, if this be necessary. Neither species require much rooting space, but it is advisable to raise them well above the rim of the pot. The pots used should be three-fourths filled with drainage materials. Above this the compost may consist of rough peat and clean-picked sphagnum-moss in equal parts, a few crocks or broken pieces of limestone about 1 inch square being mixed with it. When well rooted into the new soil, both species may be given abundance of water both at the root and overhead.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Creeping and Climbing Plants.—The fastening of these plants on walls and trellises should be attended to in mild weather, carrying out first the necessary pruning, bearing in mind when performing the last to distinguish between plants which bloom on last year's shoots and spurs, and those that flower on the new growths; climbing plants that bloom on the previous year's wood being better left unpruned till the flowering season is past, and merely, at this season, removing redundant and weak or flowerless shoots, and topping those that have attained the limit of allotted space. Whereas, the latter may be pruned much after the manner of stone fruit, leaving long and short flowering-spurs when it is the habit of the plant to produce these. Avoid crowding the shoots, make the main branches thoroughly secure, and do not fasten every shoot close to the wall, rather allow some of the shoots to hang somewhat unrestrained. A heavy mulching of rotten-manure should be placed over the roots of climbing plants, covering it with fresh mould. In selecting climbers for a new border it is well to give a thought to those whose flowers are useful in a cut state. For general purposes the following are very useful:—*Ampelopsis Veitchi*, this variety needs no nailing, as it clings to the smoothest substance with great tenacity; *A. purpurea*, a dark foliage variety; *A. hederacea*, the common Virginian Creeper; and *A. Hoggi*, the largest leaved variety; *Garrya elliptica*, *Kerria japonica*, the different varieties of *Lonicera*, *Passiflora coerulea*, the common Passion Flower, and its white progeny, *Constance Elliot*; *Pyrus japonica*, and for late autumn, the yellow-flowered *Jasminum grandiflorum*; and for winter bloom, *J. nudiflorum*, *Wistaria sinensis*, and its white variety. Of Roses, Dundee Rambler, the white and yellow Banksian Roses, Paul's Carmine Pillar, Blairii No. 2, Félicité-Perpétue, and Bennett's Seedling, and the many species and varieties of *Clematis*, not forgetting the early and abundant flowerer *C. montana*. In planting climbers against a wall it is advisable to keep the roots of the plants as far away from the set-off of the wall as possible, otherwise the plants will suffer severely from lack of moisture in the summer unless large quantities of water are afforded the borders. The soil should be deeply dug and liberally manured, and allowed a few weeks to settle down before the plants are fastened to the wall. Large tree-roots can be made effective by covering them with *Clematis*, Honey-suckles, and Roses; as may also the stumps of trees, without removing them from their places.

Carnations.—The layers planted in October have made some amount of growth, so mild has been the weather. A careful watch should be kept for grubs of various kinds, especially those of the weevils, and for wireworms, which are very active just now. For the last-named, sliced Carrots and stumps of Cabbage stuck in the soil form attractive baits. Afford water carefully to Carnations in pots, and remove dead and decayed foliage, affording air in abundance when it is not raining or it is very frosty; and let the ground be got in readiness for planting them in the month of March, liberally manuring it with rotten-dung and

leaf-soil, and if the soil is retentive, use plenty of sharp sand or road-grit, and throw the soil up roughly for the elements to pulverise.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Tomatos.—Plants established in 4-inch or 5-inch pots may now be planted at a distance of 15 inches apart in lines in shallow borders in a house previously prepared and cleaned. Only a small quantity of soil need be given at first, as additions can be made afterwards as the plants require it. Use a porous soil, such as one consisting of three parts loam to one of old lime rubbish, or burned earth. After planting afford the soil water, repeating the application as often as it becomes dry. The temperature should be about 60° at night, and 65° in the day, with a rise of 10° by sun-heat. Keep a little ventilation open at the top of the house whenever the weather is favourable. The plants will produce ripe fruit in May, and continue to bear throughout the summer, if they have sufficient space in which to grow. The one-stem system is the best mode of training Tomatos, therefore all side-shoots must be pinched off; and for this purpose look over them twice a week. Another sowing may now be made.

The Raising of Vines from Eyes.—The general method of propagating the Grape-vine is by means of "eyes," that is lengths of matured one-year-old shoots furnished with one bud or "eye," and the present is a very suitable period to strike them. When propagating Vines, consideration should be given to the purposes they will be put to, whether for planting in the vinery border, or fruiting in pots when one or two years old. The best varieties for general use when fruited early in pots are the Black Hamburg and Foster's Seedling. The best eyes are those from the lower part of last year's lateral shoots. In preparing the eyes, cut the wood slightly slanting $\frac{1}{2}$ inch above the eye and 1 inch below it. Some growers place the eyes in small squares of turf, and some in large 60-sized flower-pots, and I think the latter is the more convenient method. The pots should have one crock over the hole, and be filled to within $\frac{1}{2}$ inch of the rim with loam mixed with about $\frac{1}{3}$ of its bulk of silver-sand, one eye being placed in the middle of each pot with the point of the bud slightly beneath the surface of the soil. Press the soil firmly into the pots, and closely round the cutting. Plunge the pots in a light part of a propagating-pit, or in a dung-bed frame with a bottom heat of about 80°; and keep the surface of the soil slightly moist until growth commences; then treat them as rooted plants, affording water when required—that is, when the soil is approaching dryness. When well rooted, and before they get root-bound, shift them in 48's, and continue warm vinery treatment.

Vine Borders.—If young Vines are going to be planted later in the year, the needful preparations may now be carried out, which may consist of removing the soil and drainage, and replacing the latter, and filling in with the new compost. The depth of a border may range from $3\frac{1}{2}$ feet to 4 feet, allowing 1 to $1\frac{1}{2}$ foot in depth for drainage, and about $2\frac{1}{2}$ feet for soil. A layer of 4 to 6 inches of concrete should be spread over the bottom, upon which the drainage rubble may be laid; and for a Vine-border inside the house the slope of the floor should be towards the back of the vinery, and for an outside one, towards the front wall of the border, in both cases, outlet drains being provided. The fall of the concrete floor inside is applicable to a lean-to vinery, but for a span-roofed house it should fall from the side to the centre, and again from the centre to the ends, the place for the outlets. The concrete should be allowed to set before putting in the drainage materials. Broken bricks form a good kind of drainage if placed on their sides and ends by hand, commencing with the larger pieces at the bottom—half bricks—and finishing with the smaller. A suitable soil for the Grape-vine consists of eight parts middling heavy loam, cut from 4 to 6 inches thick from an old pasture-field, charred soil one part, and lime-rubble one part, with a 5-inch potful of bone-meal to each wheelbarrow load of soil. Prepare the lime-rubble by sifting it in a half-inch sieve, to deprive it of the dust, the coarse siftings being the only part used. These aid the percolation of water through the soil, furnish a food when dissolved by rain useful for the Vine, and tend to keep the soil porous and sweet for a great many years. Before filling in the soil, place fresh sods over the drainage, grass side downwards. The soil should be put in, in layers, well treading or ramming it as it is filled in;

consequently, it must not be in a wet condition. I advocate the piecemeal method of making a border, a piece the length of the border and 4 feet in width being sufficient for one year, additions being made each year when found necessary, but completing the inside border the first. Be particular in allowing nothing of a woody nature going into the borders, such as the roots of trees, which are apt to come in with the loam, as these cause the growth of fungus in the soil.

THE KITCHEN GARDEN.

By J. W. MCHATTIE, Gardener, Strathfieldsaye, Hants.

Rotation of Crops.—This is an important subject, and should be practised in every garden. Cabbages, and all crops of that kind, should not follow each other upon the same land. Nor should Peas and Beans occupy the same ground year after year. A complete change of crop is a comparative rest to the ground. If a crop has from any cause to be followed by a like one, then trench deeply, and expose the soil as much as possible to the weather by pointing it several times before sowing or planting the next crop.

Early Peas.—Let the varieties for forcing be of dwarf habit and early podders, sowing the seeds in pots filled with good rich soil not too finely broken up, so that the soil will cling to the roots when transplanting is performed. If boxes be employed, place strips of freshly-cut turf grassy-side downwards in the boxes, and on these sow the Peas in shallow notches cut in the turves, covering them with some finely-sifted soil. If the boxes are made 2 feet long, 18 inches wide, and $4\frac{1}{2}$ inches deep, and fitted with movable bottoms, they are very convenient for transporting to other houses, or to the open ground. Place the pots or boxes in a cool Peach-house, pit, or frame, afford no artificial heat unless there is every facility for the early production of pods at command. Most persons wish to have early dishes of Peas, but this cannot be realised unless care be bestowed on the preparation of the soil. Let trenches as for Celery be thrown out, digging plenty rotten manure into the bottoms, and return most of the soil to the trenches. According to the locality, the beginning of March, if it be mild, or later in that month, is a good time to plant out the Peas in the trenches in bunches of four or five plants, set out 6 inches apart in a straight row made down the middle of each trench, the stems being covered to a depth of 2 inches with fine soil, either consisting of the staple, or potting-bench refuse. A small ridge of soil may be drawn up to the rows on either side, but not quite touching the plants at this time. This done, stick small shoots of Laurel, Yew, or Fir along the rows as a protection against frost and wind. Good varieties for early work are American Wonder, 10 inches high; and Chelsea Gem, 16 inches high; both good flavoured, and excellent early Peas.

Large Onions.—A sowing may now be made in warmth of 50° to 55° of Ailsa Craig, or other variety of large growth, sowing the seed in pans or boxes filled with rich light soil, first pressing it firmly down, and covering the seeds lightly, using the hand to make the surface quite firm. Afford the soil tepid-water with a fine rose-can, and place sheets of paper over the boxes, &c., so as to check evaporation, as the less water applied before the seeds come up the better. On the appearance of any of the seedlings, place the pan or box near the glass, and afford air in small amount in mild weather, the chief danger to guard against being drawing. When large enough to handle, prick the plants out into boxes filled with two-thirds rich turfy loam, and half-rotten leaf-mould one-third, and grow them on in a warm pit or greenhouse without check till April, then harden-off, and plant out in a sunny position, in soil prepared early in the winter by trenching and heavy manuring. The plants may stand at 9 inches apart in the rows, the latter being 18 inches apart.

Tomatos.—At this date seed may be sown in well-drained pots, filled with light soil barely covering the seeds with finely-sifted mould, and placing the pots in a temperature of 60° to 70°, a bit of glass being put over each. Varieties suitable for early cropping are Early Ruby, Frogmore Selected, Conqueror, and Hackwood Park.

General Remarks.—The stores of Potatos, Onions, Carrots, Beet, and other roots and bulbs, should be examined in bad weather, removing all that are beginning to decay. Attend closely to the various hot-beds, affording air in small amount when the nights are mild, so as to strengthen the plants therein, and allow the redundant moisture to escape; and in order that this can be done, the linings must be kept up, and changed when they have become cool.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

JOHN LINDEN.

THE year has hardly opened before we are called on to record the loss of an intrepid traveller, a keen botanist, an enthusiastic collector, one who has probably been the means of introducing a larger number of interesting plants to cultivation than any of his colleagues, and a man of well-nigh unrivalled information on matters horticultural. JEAN LINDEN died peacefully on the 12th inst., in his eighty-first year. His death had, we believe, been anticipated for some little time, but for those of us who remember his military bearing and active habits, his removal comes as a shock. JEAN LINDEN was born at Luxembourg in 1817, but removed to Belgium, and was one of the very first students at the Faculty of Sciences in the newly founded University of Brussels. His subsequent career was sketched in outline by himself at a complimentary banquet offered to him and his son LUCIEN by the Society known as the Orchidéenne. From that account we take most of the following details. In 1835 he was entrusted by the Belgian Government with a scientific mission to South America, in company with FUNCK and GHIESBREGHT, two men who also achieved note in the field of horticulture and botany. The party landed in Brazil in December, 1835, after a voyage of three months—a journey now accomplished in little over a fortnight.

“He (Linden) explored the provinces of Rio, Spiritu Santo, Minas, Geraes, and San Paolo. The collections brought by him from Brazil in 1837 were publicly exhibited in Brussels. In December, 1837, he traversed the north and west of Cuba; the following year he penetrated into the interior of Mexico, in

spite of the many dangers to which he was exposed by the warlike condition of this unfortunate Republic. He visited the Anahuac plateau, the volcano Popocatepetl, the peak of Orizaba, and all the eastern slopes of the Mexican Cordilleras. After two years of incessant travel and most fruitful research in this rich corner of the vegetable kingdom, he embarked at Vera Cruz for Campeachy, whence he extended his observations to Yucatan. It was on one of these expeditions to the Laguna de Terminos that he contracted a severe attack of yellow fever, from which he recovered as by a miracle, but it was followed by a painful convalescence, lasting three long months. He was scarcely restored to health when he journeyed by sea into the Tabasco State, then explored the high regions of Chiapaz, penetrated into North Guatemala, then in revolution, and returned along the Gulf of Mexico. At the end of 1840 fever detained him at Guadalupe de

It may be noted that while at Bogota he fell in with HARTWEG, then collecting for the Horticultural Society of London; and when on an excursion with him to Pacho in 1841, they lighted upon *Odontoglossum crispum*, the most popular of Orchids, but one which was not generally introduced into cultivation till 1863. Little was known then of the extreme variability of this species, and hence it received the names of *Alexandrae* and *Bluntii*, names which are now tacitly discarded in favour of the original appellation.

“From Caracas, M. LINDEN travelled westward in the delightful valley of Aragua, passing by San Mateo, where Bolivar, the emancipator, was born. From Valencia he proceeded northward, and having again climbed the mountains, he descended to Puerto-Cabello, whence he left for Barquisimeto, passing by

THE LATE M. JEAN LINDEN

Frontera, whence he visited the United State in passing by Campeachy and Havanna. In 1841 he returned to Belgium, where he took some weeks' rest, preparing for a long voyage which he proposed to make to Columbia. By a happy chance he was put into communication with the illustrious Alexander von Humboldt. . . . On Dec. 27, 1841, M. Linden arrived at Guara. Directly he landed he explored the sides of the Cordilleras of the Venezuelan coasts, the base of which are washed by the waves of the Caribbean Sea, and whose crests are hidden in cloud. He travelled the elevated slopes of the Cerro de Avilo, ascended the Silla of Caracas, and then devoted three months to exploring the province of Caracas. During these excursions the traveller was more especially occupied with ascertaining the possibility of growing Orchids in cool temperatures. In an expedition on one of the highest summits of the Cordilleras, he found Orchids in bloom in a region where the temperature falls to freezing-point every morning. The proof was found, and he could confidently imitate Nature.”

the forest of San-Felipe, the morbid emanations from which are greatly dreaded. He crossed the steppe of Quibor. At the foot of the first slopes of the Andes he was stopped by the Rio Tocuyo, which the rains had changed into a torrent. He forced a passage at the cost of some mules, and the collections which had been amassed since leaving San-Felipe. He continued to scale the slopes of the Cordilleras, and stopped at a “ranche” situated at about 9000 feet (2750 metres) altitude, where in spite of the cold mornings (—2°), he found a rich mountain flora. At these elevations he more than once found the ground hard with frost, but in spite of that gathered abundant harvests. He crossed the redoubtable Paramo de Macuchies, situated 13,000 feet (4012 metres) above sea-level, and arrived at Merida, the chief town of the province of that name. He devoted several months to a fruitful exploration of this province and of Trujillo. He crossed the Rio Tachira and penetrated into the province of Santandar in New Grenada, turned southwards, and traversed the provinces of Soto, Socorro, and Velez, arriving at Bogota in October

FIG. 17.—*RESANTHEA VESCHOOTIANA*: FLOWERS ORANGE-RED. (SEE p. 42.)

1842. He visited the high plateau and the surrounding mountains. In December he descended from the cold regions towards the basin of Rio Magdalena, which, opposite Melgar, 350 leagues from the mouth, is already 325 feet (100 mètres) broad; he crossed this river by swimming, traversed the great plains of Espinal, and stopped at Ibogué, chief town of the province of Mariquita, situated at the foot of the mountains of Quindiu and the majestic peak of Tolima, the snowy summit of which towers above all the Eastern Cordillera of New Grenada. He ascended Tolima, reaching the snow limit, where he camped on January 5, 1843, at an altitude of 15,000 feet (4930 mètres). During many weeks he explored these high latitudes, then penetrated into the vast forests of Quindiu, and from there into the low regions of the Cauca Valley, which extends to the coasts of the South Sea. On August 17 he returned to Caracas; he left on November 16 from Guayra for Puerto Cabello, whence he went to Rio Hacha, beside New Grenada, to explore the mysterious Sierra Nevada of Santa Marta, which he traversed thoroughly. After innumerable dangers he reached the summit of Neveda, 14,766 feet (4800 mètres) in altitude, seeing from this culminating point the Caribbean Sea, the lake of Maracaybo, all the peninsula of Goajira, the high mountains of the province of Ocaña, the river Magdalena, and the low forests of Darien. He then made a not less perilous excursion into the interior of Goajira, inhabited by ferocious and cannibal Indians. He embarked at Rio Hacha for Jamaica, and thence went to Cuba, of which the eastern part, covered with high mountains, had not yet been scientifically explored; for six months he explored these coasts, which he left after the terrible storm which devastated this isle in October, 1844; he returned to the United States, and to Europe finally, after ten years of travel, in October, 1845."

LINDEN was for several years director of the Zoological Gardens at Brussels, and consul for Luxembourg.

After the death of AMBROISE VERSCHAFFELT, LINDEN established himself as a nurseryman at Ghent, but eventually returned to Brussels, where in conjunction with his son LUCIEN, he established the model establishment known as the *Horticulture Internationale*. His great knowledge of plants and of the localities in which they grow naturally, was of great service to numerous collectors sent out by him, or under his auspices. LINDEN's contributions to Horticultural literature have also been very great and substantial. The *Illustration Horticole*, the *Lindenia*, and other illustrated works carried on for a series of years form very valuable contributions to our knowledge of plants. LINDEN received very numerous marks of honour from his own and from various continental governments.

RENANTHERA IMSCHOOTIANA. — *Renanthera coccinea*, the oldest known species of the genus, is always admired when it flowers, but two things are generally urged against it, viz., its rambling habit of growth, and the difficulty of flowering it. The Assamese species, *R. imschootiana* (fig. 17), however, is a plant of dwarf and neat habit, and so far as can be judged by the limited experience of it in gardens, a most floriferous one. It first flowered with Mr. A. VAN IMSCHOOT, of Mont St. Amand, Ghent, in 1891, and it was named in honour of that ardent lover of rare and curious Orchids. On June 11, 1895, the specimen we here illustrate was exhibited by E. H. WOODALL, Esq., of St. Nicholas House, Scarborough (gr., Mr. HUGHES), at the Royal Horticultural Society, when the Orchid Committee voted it an Award of Merit. It is one of the prettiest introductions which Messrs. F. SANDER & Co. have made, and an additional circumstance in its favour is that it thrives well in a tolerably cool intermediate house. The prevailing colour of the flowers is a brilliant scarlet-crimson, with a slight trace of orange, the broad lower sepals being of that colour. The narrow upper sepal and the petals are

white, changing to yellow, the lower halves bearing some small, and the outer halves larger crimson spots.

ROYAL HORTICULTURAL SOCIETY. — The Council having been consulted as to a proper mode of the use of the Victoria Medal by members of the trade, have decided that the only permissible method is by the [use of the] letters V.M.H. following the name of the holder of a Medal. No other mention of the Medal can be properly made in any application pertaining to horticultural trade, or relating thereto. By order of Council, W. WILKS, Sec.

LINNEAN SOCIETY OF LONDON. — On the occasion of the meeting of this Society on Thursday, December 16, FRANK CRISP, LL.B., Treasurer and Vice-President in the chair, Mr. W. CARRUTHERS, F.R.S., exhibited and made remarks upon a fungus (*Rossellinia ligniaria*) which had been found to attack living Ash-trees, eventually causing the death of the tree. Additional observations were made by Mr. GEORGE MURRAY and Professor FARMER. Messrs. H. and J. GROVES, F.L.S., communicated a paper on some *Characeæ* collected by Mr. T. B. BLOW, F.L.S., in the West Indies, one of which appeared to be new to science. Specimens of the plants described were exhibited.

— The next meeting of the Society will be held on Thursday, January 20, at 8 P.M., when the following papers will be read:—Dr. W. G. RIDGEWOOD, B.Sc., F.L.S., "On the Larval Hyobranchial Skeleton of Anurous Batrachians, with special reference to the Axial Parts;" and Mr. R. H. BURNE, "On the 'Abdominal-pore' in the Myxinidae." (Communicated by Professor HOWES, F.R.S., Sec. Lin. Soc.) Exhibitions:—Mr. J. E. HARTING, F.L.S. A series of photographs of the Grey Seal (*Halichærus grypus*) at various ages, taken from life on the Isle of Jura by Mr. HENRY EVANS.

GHEENT QUINQUENNIAL. — The ordinary saloons of the Ghent Casino, large and numerous though they are, do not suffice to contain the myriads of plants which are sent for exhibition. An annexe has therefore to be erected, and the plans for the structure are, according to the *Revue de l'horticulture Belge*, just decided on. It will be of wood, and will comprise an area of 3105 square mètres (a square mètre = 1.19 yard). The glass roof will be shaded by a light velarium, which is well adapted to allow the plants to be seen under the most favourable conditions as to light.

GARDENERS' ROYAL BENEVOLENT INSTITUTION. — We learn that the Duke of PORTLAND has fixed Wednesday, June 8, for celebrating the fifty-ninth Anniversary Festival Dinner of the Gardeners' Royal Benevolent Institution at the Hôtel Métropole.

LOUGHBOROUGH AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION. — The opening meeting of the above Association was held on January 4. The lecturer, Mr. J. LANSDALL, of Barkley Hall Gardens, Leicester, giving on this occasion a lecture on "Soils." A very interesting and instructive lecture, over which Mr. A. HAMSHIRE presided.

BOTANICAL MAGAZINE: The following plants are figured in the January number:

Camoensia maxima, Welwitsch. — The noble West African climber figured originally in the *Trans. Linn. Society* (1866), vol. xxv., and in the *Gardeners' Chronicle*, 1896, p. 596 (figs. 105, 106). It was, it seems, discovered as long ago as 1816 by Christian Smith, a botanist attached to Capt. Tuckey's Expedition to the Congo, and whose specimens are preserved in the British Museum; t. 7572.

Paphiopedilum Victoria-Mariæ, Rolfe, in *Orchid Review*, iv. (1896, p. 364). — "The time has come," says Sir Joseph Hooker, for separating generically the tropical from the temperate species of *Cypripedium*, and adopting for the former the name *Paphiopedilum*, proposed by Dr. Pfitzer. Besides the wide difference of geographical distribution, the true *Cypripedia*

being all natives of the cooler temperate regions, and the *Paphiopedila* of tropical Asia and Australia, the following characters distinguish them. In *Cypripedium* proper the leaves are cauline, thin, and plicate in veneration, the perianth marcescent, and sepals valvate in æstivation. In *Paphiopedalum* the leaves are radical, coriaceous and conduplicate in veneration, the perianth deciduous, and the sepals imbricate in æstivation, the dorsal enfolding the lateral." We must receive this pronouncement with the greatest respect and deference, but we are sorry the old genus was not retained with such sub-divisions as might be necessary. *P. Victoria-Mariæ* is a native of Sumatra whence it was imported by Messrs. Sander; t. 7573.

Strobilanthes Dyerianus, Hort. Sander. — *Gardeners' Chronicle*, 1893, p. 442. Burma; t. 7574.

Lathyrus splendens, Kellogg. — See *Gardeners' Chronicle*, 1893, vol. i., p. 258; and 1897, vol. i., p. 315 (fig. 106).

Sievelkingia Reichenbachiana, Rolfe, MSS-Gorgoglossum-Reichenbachiana, Lehmann, *Gard. Chron.*, 1897, i., 346. A curious genus of the sub-tribe *Oncidiæ* with clustered ovoid pseudo-bulbs, each producing a single stalked, oblong lanceolate, multicostate leaf; flowers racemose pendulous, each about 1½ inch across, with three greenish ovate acute sepals, two lateral petals as long as the sepals but deeply fringed and covered with golden hairs. The three-lobed lip is similarly fringed, its disc marked with purplish spots. It is a native of Ecuador; t. 7576.

STOCKTAKING: DECEMBER, 1897. — We subjoin our customary remarks on the trade of the country so far as it affects horticulture. IMPORTS—these are placed at £41,332,284, against, for the same month in 1896, £43,618,851—a decrease of £2,286,567. Here may fittingly be given our usual extracts from the "summary" table of imports:

IMPORTS.	1896.	1897.	Difference.
	£	£	£
Total value ...	43,618,851	41,332,284	—2,286,567
(A.) Articles of food and drink—duty free ...	14,964,039	14,338,976	—625,063
(B.) Articles of food and drink—dutiable	2,501,614	2,621,073	+119,459
Raw materials for textile manufactures ...	10,352,499	8,257,787	—2,094,712
Raw materials for sundry industries and manufactures	3,521,583	3,794,260	+272,677
(A.) Miscellaneous articles ...	1,560,380	1,593,153	+32,773
(B.) Parcel Post ..	52,358	59,257	+6,899

Now, as to fruit, &c., take the following explanatory and suggestive figures:—

IMPORTS.	1896.	1897.	Difference.
Fruits, raw:—			
Applesbush.	1,186,464	410,954	—775,510
Cherries"
Plums"	...	604	+604
Pears"	8,691	11,892	+3,201
Grapes"	7,422	1,634	—5,788
Unenumerated"	53,734	8,827	+25,093
Onions"	452,235	435,079	—17,156
Potatoescwt.	32,147	472,867	+440,720
Vegetables, raw, unenumeratedvalue	£64,465	£73,021	+£8,556

Those interested in the festive season consumption of Oranges and Lemons are informed that the import of the former during December amounted to 1,816,013 bushels, against 1,773,134 bushels in the previous December, being an increase of 42,879 bushels; Lemons foot up at 139,129 bushels in the past month, against 211,452—or a decrease of 72,323 bushels as compared with the same period in 1896. In casually glancing at our market reports, the prices attached to Pine-apples in all markets will be found to be well maintained, notwithstanding the fact that the imports of recent days have increased by many thousands in number, owing to the fact that Orange-culture has

a given up in various situations, Pines taking place; the home-grown article generally brings highest price. Turning now to

EXPORTS,

unpleasant to record a fall of £1,015,578, compared with December, 1896. The total exports were £302,181; in 1896 the figures stood £20,317,759. partial reconstruction of the American tariff, and trade dispute at home, are responsible for much of decrease, apart from the disturbing political elements.

KEW PALACE.—In one of our Jubilee numbers gave an illustration of the old Palace at Kew, and are now enabled to add that HER MAJESTY has led that this building shall be opened as a museum under the same management as Kew lens; and by her wish the grounds belonging to

the part of the *employés* to make two presentations—one from the indoor staff, to Mrs. J. CYPHER, and another from the outside staff to Miss CYPHER, both of which were intended to mark the appreciation by the men of many kindnesses they had received. The pleasant hours that followed furnished evidence of the happy relations that exist between the proprietor of this establishment and his workmen.

CHESTER PAXTON SOCIETY.—The opening meeting of the above Society's annual winter session was held in the Grosvenor Museum, Chester, on Saturday evening last, 8th inst., under the presidency of Mr. BARNES, of Eaton Gardens, and the opportunity was embraced of presenting Mr. G. P. MILN, the Hon. Secretary for the past eight years, with a gold watch and chain as an expression of the Society's thanks for the valuable services he has all along rendered to the Society.

FIG. 18. — KEW PALACE IN THE ROYAL GARDENS, KEW.

(Lately opened for public use at the command of HER MAJESTY.)

what is known as the "Queen's Cottage" will also be utilised in connection with the Royal gardens. The palace is close to the northern entrance to the gardens, and was a favourite residence of GEORGE III., and of CHARLOTTE, Princess of Wales, daughter of GEORGE IV., who afterwards married LEOPOLD I., King of the Belgians. Princess CHARLOTTE, then Queen CHARLOTTE, died there in 1817 in childbirth. It must be remembered that the cession for public use of the whole of the Royal gardens is due to the generosity of HER MAJESTY. The Queen's cottage is a picturesque thatched building in a sequestered nook at the Isleworth end of the gardens, surrounded by plantations and, in their season, the wild Hyacinths form a flush of colour than which nothing can be more beautiful.

PRESENTATION AT CHELTENHAM.—The *employés* of Mr. J. CYPHER, of Cheltenham, were entertained by him at a dinner on the 7th inst., in one of the glasshouses on the premises, partly in celebration of Mr. CYPHER's seventieth birthday. This auspicious occasion was taken advantage of on

PRESENTATION TO MR. J. W. WILKINSON.—A considerable gathering of those associated with Mr. J. W. WILKINSON, the Secretary of the Royal Aquarium and Summer and Winter Gardening Society, in carrying out the various exhibitions held in that building, his colleagues in administering its affairs, and of personal friends, took place at the Westminster Palace Hotel, on the 11th inst., on the occasion of a presentation to him on his approaching marriage on the 20th inst. The testimonial consisted of a massively-framed illuminated address, warmly appreciative of Mr. WILKINSON's work as the secretary of the Royal Aquarium Co., and of the esteem in which he is held. A purse of 100 sovereigns was also presented him. In the unavoidable absence of Mr. C. J. NOBLE, the chairman of the Testimonial Committee, Mr. R. DEAN, the secretary of the National Chrysanthemum Society occupied the chair.

"REVUE HORTICOLE."—M. H. DAUTHENAY is now associated with Mr. ED. ANDRÉ in the editing of the *Revue Horticole*, a journal which for nearly three-quarters of a century has held the foremost place in France, and has amply deserved it.

ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION.—This energetic body of gardeners and amateurs seem by their balance-sheet to be deservedly prosperous; but it is scarcely just to measure its usefulness by its monetary statement, much good to horticulture in the garden isle accruing, the value of which it is impossible to estimate. The syllabus of lectures for the current year is a varied one, the names of several good cultivators being found among the contributors of papers.

"THE HORTICULTURAL DIRECTORY AND YEAR-BOOK FOR 1898" is now before us, and we welcome it as an indispensable book of reference, that is destined to become well thumb-marked before the year has run its course. Besides being as complete a Directory as possible of the principal garden and nursery establishments in Great Britain, the book contains much information to which a gardener has frequently occasion to refer. In its thirty-ninth year it has become larger than ever. The book is published at the Office of the *Journal of Horticulture*, 12, Mitre Court Chambers, Fleet St., London, E.C.

"MY GARDEN DIARY FOR 1898," published by Messrs. SUTTON of Reading, is one of the neatest and prettiest things of the kind we have seen. The information given is most serviceable, and conveyed in the simplest language; whilst the commercial element is where it is wanted, and not where it is in the way.

ROYAL BOTANIC GARDENS, CALCUTTA.—The magnificent gardens across the Hooghly River have been ruled over by a long line of illustrious botanists—botanists whose reputations have been world-wide. Wallich, Roxburgh, Griffith, are names which recall the early struggles of a science to establish its roots in the East and spread its branches. Sir George King, the retiring Superintendent, has, perhaps, done more to popularise and extend the usefulness of the Royal Botanic Gardens, Calcutta (or Seebpore, to be more exact), than any of his illustrious predecessors. He has ruled over its destinies for many years. Sir George King will be succeeded by Dr. David Prain, who has, for several years held the post of Curator of the Herbarium of the Royal Botanic Gardens, Seebpore, where he has done excellent work. No better selection could have been made, and we congratulate Dr. Prain on his appointment, and the Government of India on their sagacity in putting the square man into the square hole for once. Dr. Prain is an erudite scholar, and a high authority as a botanist. He is the author of several learned botanical monographs, and we have every confidence that under his rule the Botanic Gardens will continue to extend their usefulness in the future as they have in [the] past under the guidance of the genial and learned gentleman whom Dr. Prain succeeds.

"THE GARDEN."—The monthly part, ending December, has reached us. It contains among other things effective coloured illustrations of some of MARLIAC's hardy Water-lilies. The plate of *Erigeron speciosus* gives an excellent idea of the plant as a whole, though details are wanting. It is to be hoped that the figures of *Hibiscus syriacus* may lead to the more frequent cultivation of these beautiful autumn-flowering shrubs.

MARRIAGE OF MR. BERNARD COWAN.—The marriage of Mr. Bernard Cowan, Superintendent of the South Shields Burial Board, with the widow of the late Mr. Peter Marshall, of South Shields, which took place on the 13th ult., may be matter of interest to many of our readers in Durham and Northumberland. Mr. Cowan is an accredited lecturer on horticulture for the Durham County Council, and is, we believe, the only lecturer for this year. He was the first chairman of the Newcastle and District Horticultural Mutual Improvement Association, and is one of the vice-presidents of the English Arboricultural Society. He is also secretary of the South Shields and Northern Counties Chrysanthemum Society.

PRESENTATION OF AN ADDRESS TO MR. HUGH DICKSON, OF THE ROYAL NURSERIES, BELFAST.

A NUMEROUS company of the friends of Mr. Hugh Dickson, of the Royal Nurseries, at Belmont, Belfast, assembled recently in that city to do him a well-merited honour as their guest at a complimentary dinner, and to present him with a handsomely illuminated address, mainly in recognition of his invaluable services to the Ulster Horticultural Society. Mr. Dickson, who is so widely known and popular among rosarians in the United Kingdom, is the younger son of Alexander Dickson, a Scotchman, from Midlothian, who, after being employed for some years as a gardener, established himself as a nurseryman, in 1836, at Newtownards, co. Down, where Hugh first saw the light, and received his early training. A well-earned success in business had not absorbed all Mr. Dickson's time and energies, and none has been more ready and willing to lend a helping hand, when such was required, to promote the interests of horticulture in all its branches among his friends and neighbours in the north of Ireland or elsewhere.

Chiefly at the inspiration of Mr. Dickson, the Ulster Horticultural Society was started afresh at Belfast about ten years ago. Since then its progress has been a continued and marked success, in all of which he has been the moving spirit. The complimentary dinner was presided over by Thomas Shaw, Esq., J.P. who in proposing the toast of the evening, "Their Guest," said he warmly congratulated their guest on the thoroughly representative character of that large assemblage of his friends.

The toast having been cordially responded to, Mr. Dickson, who was enthusiastically received on rising, expressed his heartfelt thanks to his many friends for that marked expression of their goodwill. He was conscious of the fact that the compliment paid to him that evening was initiated by the Horticultural Society, and he rejoiced to see so many members of that body present. It was unnecessary for him to speak of the success with which that society had carried on its operations. It was, however, right for him to say that a more united body than the committee of the Ulster Horticultural Society it had never been his privilege to work with.

NURSERY NOTES.

A "NEW YEAR'S SHOW" AT READING.

LEAVING London soon after 8 A.M., early in the present month, there was no snow, nor hoar-frost; no hard, clear roads—not a circumstance, in any degree suggestive of January, but rather of April. When Reading was reached the air was clear, and the sun bright and warm, but Messrs. Suttons' "flower show" commanded our admiration for all that. Previous to this we made a call at the establishment in the Market Place, where the roguing and cleansing of seeds, by hand as well as by the wonderful machines, was in full progress. There appeared to be Peas sufficient to sow the empire over, and we watched the women as they hand-picked these and other seeds, as French and Broad Beans, Scarlet Runners, &c., each on the outlook for "wastes;" for, in proportion to the number they found, so would their earnings be.

Following our guide to another room, half-a-dozen men were weighing and putting Peas into quart, pint, and half-pint paper bags, as if for a wager. We will omit to give figures of the quantities per day so dealt with, lest we be suspected of exaggeration; and further, interesting as these items were, we had come to see the new year's show at the nursery, and to enjoy it. What a picture of Flora in winter it presents! filling each house, and overflowing, so it seemed, until the effect was noticed as soon as the entrance to the nursery was gained. The display was profuse enough, sufficiently bright and many hued, to impress the visitor with the utmost sense of satisfaction, notwithstanding every house was filled with bright sunshine. From the "spectacular" point of view the success was unqualified. We venture to think also, that if the visitor has ever studied the

capacity Nature possesses to effect change in a plant, something we have grown to describe as evolution, he will be sure to do so as he admires the beautiful and

HIGHLY CULTIVATED PRIMULAS,

in which differences in leaf and flower and habit have been induced by selection, and by excessive cultivation from the species *P. sinensis*. In foliage alone, the types known as Fern-leaved, Palm or plain-leaved, and moss curled-leaved, are very distinct from each other, not to mention minor differences exhibited by the plants, such as larger or lesser-sized leaves, and the average number of leaves to a plant. Flowers are single and double, and in colour there is exceeding variety, embracing, so it would seem, all tints but yellow and true blue. In regard to the last-mentioned colour, although the ideal blue Primula has yet to be raised, we appear to be gaining ground in that direction, and a variety we shall mention presently is a pleasing, if not a "true" shade of that colour. In the case of the Reading Primulas they have been the care of a cultivator who has spent the greater part of his life in a study to improve and cultivate a few species of plants of which the Chinese Primrose is one. In the pursuit of this work, he has learnt much of the power the cross-fertiliser may yield, and he has learned more, and that is, that there are limits to his field of influence. For a long time it is possible that nothing but success follows the efforts he may make to improve a type or to "fix" a characteristic, but there comes a time, sooner or later, when he reaches the limit in that direction, and further steps he may take are backward rather than forward. In his own words—"If we only knew when to stop!" But apart from the knowledge that comes from intimacy with certain principles, and from actual observation during many years (which is not conclusive in any case), there is no certain indication; and in seeking to further improve a flower that has responded to previous coaxing, may be sterility is reached, which is one of the troubles that the cross-breeder of florist's flowers has to guard against, particularly if the stock has to be increased from seeds, as Primulas are. But the cross-breeder may see qualities of leaf, of flower, and of habit, in several different plants, and by successive crossings conducted on the principle that "like begets like," he may subsequently succeed in embodying these characteristics in one plant.

High cultivation, too, plays its part, and to this should be ascribed the variations that occur, and that cannot be traced to cross fertilisation. We were interested to hear that the strain known as "Giant Primulas" was not obtained by intelligent crossing, but first appeared unexpectedly. Its characteristics are chiefly these: the plants produce fewer leaves and fewer flowers, but the flowers are larger, and the habit of the plants is stronger, so much so, that they are easily identified when not in bloom. Of course, there are many varieties of the Giant strain now, and various colours, but if one of them be crossed back again to an ordinary Primula, its influence is not perceptible, and the older type seems to exert exclusive potency. Just so did the variations in the foliage of the Primula originate, being due to the effects of cultivation, and a parallel may be seen in the variations that have occurred in the leaves of the Brassicas.

In colour, perhaps, the florist can achieve most, and so far as the Primulas are concerned, the male parent is thought to be most potent in effecting change. It is interesting, also, to study the time that may elapse between the cross being made, and any visible effect arising therefrom. Our attention was drawn to several cases in which two plants with well-marked characteristics had been mated, and the issue from seed showed but little evidence of the fact. Experience, however, has taught the cultivator that this variation he has sought may appear in the second or third generation of the seedlings. The cross has been effected; the white or the pink Primula has been wedded with the "Carnation-flaked;" and though the influence of the latter is latent for a time, it will be extremely likely to appear subsequently.

Having been tempted to write thus far regarding

the cross-breeder's part in Primula development, we will briefly refer to some of the varieties that are in commerce—"fixed," of which seed may be purchased, and some of them have been favourites for a long time.

Taking the single-flowered ones first: Rosy Queen is an instance of a variety raised sixteen years ago, and still a valued one; it was the first Fern-leaved variety with pink or rose-coloured flowers. The foliage is light green, and the flowers large, of a very beautiful rosy-pink, and abundantly produced. Since 1879 the variety Pearl has been constantly good, and has improved; its large white flowers acquire a delicate pink with age, and it is well known and popular. Purity, another white-flowered one, but with beautiful dark green Fern-like foliage, is one of the very best mid-season varieties. The flowers are large and pure white, with crimped margins; stems very dark coloured. A grand late-flowered one is Brilliant Ruby, one of the very first-class red Primulas, of dwarf and capital habit. It has superseded Ruby King. There are two excellent white varieties in Snowdrift and Royal White. The former is exceedingly early, and is a perfect Primula, bearing abundance of pure white flowers over pretty Fern-like foliage. By reason of its large stigma, the bloom does not readily shake off. Royal White has pure white flowers of large size, good substance, beautifully fringed, and the foliage is dark-green and plain. Reading Blue is most praiseworthy, and if not so decided a "blue" as that afforded by some other species of flowers, it is nevertheless a tint that should be welcome in any greenhouse in January. Reading Scarlet, Brilliant Rose, and Gypsy Queen are included in the specialties of the single-flowered type.

Turning to the double flowers: in Carnation-flaked we have perhaps the strongest habited of any of the varieties. The foliage is strong and dark, and it flowers abundantly, being pure white, more or less flaked with bright carmine. A good pink is Double Pink, and very free. Double Blue is remarkable for its fine trusses of flowers of decidedly pretty lavender or pale blue colour—we strongly recommend it. Double White is a very floriferous early, pure white variety, that should be useful as decorative plants or for providing flowers for cutting. Double alba magnifica, with moss-curved foliage, has prettily fringed flowers, and may be recommended. Double flowers in bright scarlet, and effective crimson, are also equally good.

(To be continued.)

PARADISE AND VICTORIA NURSERIES.

The changes that are quickly taking place, and which few gardeners and horticultural amateurs whose memories carry them back a dozen years can fail to note in the species of plants cultivated in nurseries, are particularly noticeable in Messrs. B. S. Williams' establishment at the foot of Highgate Hill. Orchids and Palms still form the backbone of the collection of plants grown there, and very successfully are the plants cultivated under the adverse conditions of the atmosphere, and the relative lack of sunlight due to fog at times during the autumn and winter, and to coal-smoke at almost all seasons.

A visit recently made, revealed sad evidences of the effect of fog, in the absence of expanded blooms or even half-opened flower buds, and in the abundance of yellow and withered flowers and buds and old leaves, the latter especially noticeable on Cattleyas and Lælias.

A few sunny days, will, however, put a more cheerful aspect on the plants. Plenty of flower-spikes just making themselves visible, could be observed on *Odontoglossum crispum*, of which the nursery can boast of many very superior forms, on *Ceologyne cristata*, *C. alba*, *Lælia Gouldiana*, numerous *Cypripediums*, and *Lælia anceps alba*. We remarked the old greenhouse in which large plants of *Camellia* used to be grown, to very small advantage to the owners, is now filled with species of Palms suitable for ordinary decorative uses. This is a change for the better, although many persons will deplore the loss of the *Camellias*, which are, pity be it said, less fashion's favourites now than of yore. Similarly, instead of speci-

men Azalea indica, small stuff, 1½ foot in height, abundantly furnished with flower, filled an adjoining glasshouse; the former evidently made in Belgium. Azalea mollis in quantity, and masses of Tulips and Hyacinths grown in boxes in a wholesale manner for the purposes of furnishing vases, jardinières, &c., were noticed in houses that only a few years ago teemed with hard-wooded plants in variety.

The handsome variegated, narrow-leaved Dracæna Douceti was noticed in some quantity, an excellent decorative plant that stands uninjured in rooms for a length of time; Crotons in useful sizes; Aspidistra with clean unblemished foliage were observed in large numbers; also Cyperus alternifolius gracillimus, a very slender habited form, good as a table plant, and plenty of healthy Palms, such as Kentias, Livistonas, Rhaphis, &c., fit for decoration, are among the more prominent part of the stock.

HOME CORRESPONDENCE.

WHAT IS CYCLAMEN PERSICUM?—This is, I know, a question which has often been discussed, and on which competent botanists have probably made up their minds long ago. We are told, on the authority of *Index Kewensis*, that *C. persicum* of Miller—the greenhouse Cyclamen of English gardens—is *Cyclamen latifolium* of Sibthorp. My attention has again been directed to this question, because in an article on the Persian Cyclamen recently published in the Royal Horticultural Society's *Journal* (December, 1897, p. 270), I find this statement:—"Last season my memory (concerning the poorness of the early strains of Persian Cyclamen) was refreshed by a sight in Messrs. Sutton & Sons' Reading Nurseries of a batch of *C. persicum*, which had been imported direct from Persia." Now, the best authority on the flowers of Western Asia I have always found to be E. Boissier. He tells us in his *Flora Orientalis* that *C. latifolium* (of which he says *C. persicum* of Miller is the garden form), though common in Asia Minor and Palestine, is not found in Persia in any of its forms. The only Cyclamen which E. Boissier mentions as found in Persia is *C. Coum* (Miller's). So if the Cyclamens mentioned as seen at Reading really came from Persia, they belonged to *C. Coum* (Miller), which has never been identified with any form of florist's Cyclamen. Another Cyclamen, *C. græcum* (Lin.), common in Greece, but not found anywhere in Asia, was called *C. persicum* (Miller) by Sibthorp, who seems to have confused it with *C. latifolium*. Neither *C. græcum* nor *C. latifolium* is hardy in English gardens. *C. Wolley Dod*, *Edge Hall, Malpas*.

ACÆNAS.—One is pleased to see these mentioned by M. Correvon in the *Gardeners' Chronicle*, p. 28. It is to be hoped that his valuable note will lead to a little more attention being paid to the Acænas, because of their value in the Alpine garden, and as carpet-plants for covering the ground under tall plants. *A. microphylla* has few rivals as a plant for low, moist spots in peaty soil, especially when it is in fruit. I would especially refer to the two newer species which are mentioned in M. Correvon's note. These, with some others, Irish readers will be able to see at the Botanic Garden, Glasnevin, and they and others who may chance to see plants elsewhere, will agree with me in saying that the beauty of *A. Buchanani* is not exaggerated in the article to which I refer. I saw it first in the rock-garden at Glasnevin, being much struck with its colour, and the beauty of its leaves, and of its habit. *A. glabra* I have in my garden here, but it is, although pretty, not to be compared with *A. Buchanani*. One is glad to know that there is now a prospect of the new Acænas being readily obtainable from the ordinary sources of supply. *S. Arnott, Carsehorn, by Dumfries, N.B.*

HAMAMELIS, OR WITCH HAZELS.—This small genus of hardy-flowering shrubs is little known in gardens, consisting, as at present, of only three species. One, a native of the United States, and the other two from Japan, and all are deserving of culture in the shrubbery, flowering, as they do, at this time of the year, when little else is to be seen in flower, the whole of their leafless branches being covered with the curious and pretty flowers. The oldest and commonest species in this country is *H. virginica*, which, as its name implies, hails from Virginia, from whence it was introduced so far back as 1736. It flowers

from October to March, with the flowers, being of a deep yellow colour, and disposed in clusters. After the petals fall, the calyx remains till the leaves appear, in April and May. This species was described in *Botanical Magazine*, 6684, and it is sometimes met with under the name of *H. macrophylla*. *H. arborea*, introduced in 1862, is very rarely met with in this country (see Masters in *Gardeners' Chronicle*, February, 1874, fig. 47). It is the best of the Witch Hazels as regards the beauty and size of the blossoms, and makes, in its native country—Japan—a small tree from 15 to 20 feet high. A plant is now in flower at the Woking Nursery, having clear yellow flowers, with deep claret calyxes. This was, I believe, erroneously described in *Botanical Magazine*, 6659, as *H. japonica*, which differs greatly, having paler flowers, and partaking more after the habit of *H. virginica*. This species, *H. japonica*, according to *Nicholson's Dictionary*, has an allied form, known as *H. Zuccariniana*, with paler flowers and greenish-brown calyxes, but this I have never seen. [It was shown at the last meeting of the R. H. S. by Messrs. Veitch. Ed.] All are deserving of extended culture. They will flourish in any good garden soil, especially so in a moist sandy soil, such as we have at Woking. *E. S., Woking*.

A HALL FOR HORTICULTURE.—Mr. Divers is surely out of his depth when he refers to the "profits" of the Aquarium Company. He can have no personal knowledge on this point, and he repeats the imaginings of others. Mr. Divers also knows nothing of the heavy expense the Royal Aquarium Society is put to in providing for the National Chrysanthemum Society's exhibitions; all the necessary staging, labour, lighting, cleaning, &c., saying nothing about printing and posting thousands of bills, advertising, sandwich men, paragraphing the press, entertaining the representatives of the papers (!), and many other ways. Nor does he think of the many free admissions to the shows, which swell the attendance; an army of their own servants and attendants; artists and their attendants, as well as those at the side shows, shareholders, season-ticket holders, the numerous representatives of the press, 1500 passes of the National Chrysanthemum Society carrying the privilege of free admission on the three days of each show, and on the occasion of that held in November, some 300 exhibitors' passes. Further, there has to be deducted the average attendance on ordinary days, and then the margin has to defray the sum of money given to the National Chrysanthemum Society, and the heavy expense of each exhibition. Then, among the further advantages enjoyed by the National Chrysanthemum Society is the privilege of purchasing one-shilling admission-tickets at half-price, a privilege which, during 1896, brought to the exchequer of the Society the sum of over £50. In addition, is enjoyed the privilege of letting large portions of the building during the shows, and taking payment for the same. In 1896 this realised for the Society over £100. Accommodation is provided for all the meetings of the Floral Committee, and all members have free admission to these; there is also furnished gratis a great deal of storage-room, for which the Society would otherwise have to pay. Whether the gardening community is interested in the entertainments is a matter of opinion. The contributions of members go but a short way towards defraying the working expenses of the Society; and the sum of £55 was added to the Reserve Fund at the end of 1896. As to the "further encouragement of Chrysanthemum culture," Mr. Divers would never have made such a statement had he thought about the matter. No other special society can show such a record of work, furthering the cultivation of the particular flower it takes in hand, as the National Chrysanthemum Society furnishes in the case of the Chrysanthemum: its four annual exhibitions, its Floral Committee, its Classification Committee, its Conference Meetings, its invaluable catalogue, its 150 affiliated societies, its very extensive helpful correspondence, &c.; what are all these but a most valuable catalogue of helps in the cultivation of the Chrysanthemum! His deliberate statement that a "better class of persons would patronise the shows if held under better conditions" is falsified by the fact that such do attend, and in large numbers. I, who have had something to do with the arrangements of many London shows, can assert that the prime cause of failure was, that the public did not attend them, and in London no organization, not even the Royal Horticultural Society, can afford to hold exhibitions which do not pay. Let Mr. Divers, and those who sympathise with him in his attitude towards the

Aquarium, try a show in some place in London, depending upon the gate-money to re-imburse them for their outlay. The result would be disastrous, even if they made their attempt with the November exhibition of the National Chrysanthemum Society at the Agricultural Hall, or Earl's Court. *Richard Dean, Ealing, W.*

VIOLAS.—In my opinion, Dr. Williamson does not do justice to the subject. In my garden on the date he mentioned I had 200,000 plants in full bloom, and exhibited on the 10th as fine a lot of Pansies and Violas as one would wish to see, all grown in the open. To-day (January 1, 1898). I could pick a large quantity of fine blooms. My Violas start to bloom in March; in April I could exhibit them, and in the following month they are in perfection, and continue to flower profusely till the end of October. Many of those Mr. Williamson mentions I consider as being quite out of date, and I would very much like to know his opinion of Britannia, a magnificent blue; Mrs. J. Donnelly, Blanche, white; Pembroke; a yellow Kitty Hay, neither of which he mentions. Then, again, the variety Mrs. Richard Hare, a greatly improved Countess of Kintore. How many can grow a good bloom of A. J. Rowberry? It is a beautiful flower when well grown, but how very little use it is for bedding, which, in my opinion, is the proper object of a Viola. I trust Dr. Williamson will visit me during the coming seasons, my garden being open on Saturdays to lovers of the Viola, when I think the Violas will offer many surprises. *Wm. Sydenham, Tamworth*.

APPLE AND PEAR-TREE PRUNING.—Pressure of work has prevented me remarking earlier upon Mr. Kettle's criticism of Mr. Ward's advice on pruning (p. 448). Perhaps Mr. Kettle will be good enough to answer the following questions. He asserts that a great many trees would be far more shapely and fruitful if not pruned at all during the first half-dozen years of growth, and after that time he is sure they would need but little. Will maiden-trees of themselves form shapely specimens? How is the tree to make the necessary main branches? Will they form in a proper manner, even only and at the right places or positions, and if so will they be of uniform strength? What does Mr. Kettle mean by spreading varieties such as Quarrenden and "rigid ones, as Blenheims?" I most certainly have found the latter much more spreading than Quarrenden, in fact one of the most spreading of any kind I know, and if not pruned, it will throw long horizontal branches without a break, whereas Quarrenden is much more erect. I know trees will bear more quickly if left alone, but then there is soon an end of the growth, and I would rather have branches first and fruit afterwards. Mr. Kettle would teach "old hands" to throw away the knife because others do not know how to use it properly. In Cornwall here, there are too many instances of such practice, and hundreds of pounds have been wasted because old trees have not received the necessary pruning during the first six years. *Charles Hott, Hort. Inst. Cornwall C.C., Truro*.

BARBERRY AND WHEAT MILDEW.—It positively makes one feel quite young again to hear any person expressing a doubt about the connection between *Ecidium Berberidis* and *Puccinia graminis*. Mr. Morgan speaks of the common Barberry being planted by millions for hedges in many parts of New Zealand. Whether the Barberry plant will act differently in New Zealand to what it does in Europe, our friends upon the other side of the globe will soon see for themselves. It is just possible, however, that the teleutospore of the *Puccinia* may not germinate so freely with them as they do with us, owing to their "winter" temperature not being sufficiently low. I have tried on two occasions to get the teleutospore of *Puccinia graminis* from Australia to germinate in England, but I have not succeeded. The first attempt was made nine years ago, when Mr. D. Macalpine was good enough to send me material, but I was quite unsuccessful. Last year he was kind enough to send me a further supply; but although I kept the straw out-of-doors during the latter part of last winter and the spring of 1897, I was equally unsuccessful. Is it probably like the seeds of some of the higher vegetables, the teleutospores require not only a period of rest, but also an exposure to a certain degree of cold? Perhaps one should not be too positive because of having had two failures, but the point is certainly one worth attention by the numerous practical botanists who are now to be found in all quarters of the globe. *Charles B. Plowright, M.D., King's Lynn, Jan. 9*.

PEAR DUCHESSE D'ANGOULEME.—Your correspondent "H. H. R." (p. 448, vol. xxii.) says, "The remarkable experience given in your issue of Dec. 11 last concerning the above Pear as grown upon a wall seems to indicate that there is no complete connection between the treatment described and the splendid results obtained." How does "H. H. R." arrive at this conclusion? My own opinion is, and I think fruit-growers generally will agree with me in saying, that there is "a connection between the treatment described and the splendid results obtained," when coupled with other circumstances. (1) The tree in question bore no fruit in 1896; (2) it was root-pruned in the September of that year in the manner indicated in the *Gardeners' Chronicle* for Dec. 11 last (p. 419), the old and, perhaps, sour soil being replaced with a mixture of good loam and rubble, in the proportion of four parts of the former to one of the latter. (3) The tree thus operated on was already fairly well provided with fruit-buds, and these concurrently with the emission and pushing into the new soil of a host of young roots had considerably increased in size and solidity before the tree shed its leaves in November, with the result that clusters of strong, well-developed flowers appeared on the tree the following spring, which set freely, and in due time attained the dimensions set forth in the note and illustration given in the issue of the *Gardeners' Chronicle* referred to above. (4) The tree thus operated on having thoroughly established itself in the compost mentioned above, and being kept well supplied with water at the roots during the period of active growth, combined with the tropical-like weather which prevailed the whole time of the fruit's growth, go to show a "complete connection between the treatment, and the splendid results obtained" from the tree in question. And (5) to the favourable situation of Stradey Castle-gardens and their nearness to the sea, when taken in connection with the skilful and generous treatment which the gardener (Mr. Thomas Lucas) bestowed upon the tree and the exceptional heat of the sun during the summer and early autumn months may be attributed the high quality of the fruit. "H. H. R." says "The particular variety of Pear is hardly one of merit as grown in this country, as in good fruit-shows it is usually conspicuous by its absence, or very moderately represented compared with other varieties, or to the splendid examples sent us annually from France," adding, "The crop described is thus even more remarkable, and in contrast to the statement in the catalogues of the well-known Sawbridgeworth firm to the effect that this variety is usually insipid from a wall." The above remarks only go to show that all the more credit is due to the gardener who produces such remarkably fine fruits—not only "remarkable" in size, but also in appearance, being grandly coloured, and fine in flavour. The absence of good examples of Duchesse d'Angoulême Pear from good fruit-shows must not be looked upon as being the fault of this variety, but rather as failure on the part of cultivators to stage creditable examples of it. "H. H. R." unwillingly speaks most favourably of the Duchesse d'Angoulême Pear in referring to the "splendid examples of it sent us annually from France," un mindful of the fact that a few lines higher up in his note, he says "it is hardly one of merit,"—"remarkable" reasoning this! All the same, it serves to show that the variety is "splendid" when grown under favourable conditions as regards soil and climate; and when grown under conditions the reverse of these, it "is hardly one of merit;" the conditions under which the fruit was produced being at fault in the latter case, and not the variety, I candidly admit being unable to understand the validity of the extract from the Sawbridgeworth catalogue, to the effect "that this variety is usually insipid from a wall!" How is this? The flavour of Pears and other hardy fruits gathered from trees occupying positions on walls having south and west aspects being invariably superior to that possessed by fruits of the same kinds and varieties obtained from trees growing in the open, whether they be standards, pyramids, or bushes. "H. H. R." is quite right in saying that the district (Llanelly) in which the Stradey Castle Pears were grown resembles more the conditions of France than this (Forest Hill) part of the kingdom. I may here say that Llanelly and Bournemouth (where the second-best examples of the Duchesse d'Angoulême Pear coming under notice were grown) are about the same distance from, and pretty close to the sea, Bournemouth being about one degree farther south. In reply to your Correspondent's questions; root-pruning, as already stated, was done in September; the tree was growing in ordinary garden-soil, but the Carrot-shaped roots

had pushed far down into stoney and heavy soil; the tree is grafted on a Pear stock, and it had not actually failed in fruitfulness excepting in 1896, a few fruits having been taken from the trees every autumn with the exception indicated, these being of ordinary size and appearance. The tree which was root-pruned in September, 1896, is now (Mr. Lucas informs me) well-furnished with large solid fruit-buds. *H. W. Ward, Rayleigh.*

THE ROSARY.

"THE ROSARIAN'S YEAR BOOK."

THIS little volume opens with a portrait and a sympathetic notice of the life and career of the Rev. Joseph Pemberton. Miss Muriel Grahame's account of a Rose show betokens observation, and a keen sense of humour. Mr. Foster-Melliar's articles are always full of matter, and trustworthy—his article on yellow Roses is no exception. The editor sketches the progress of the Society in 1897. Mr. A. Piper gives numerous illustrations of Rose sports, which will be valuable for evidential purposes. Mr. George Paul discusses the question of showing "trebles" at Rose shows. If the treble meant a truss of three Roses, one in advance of the other two, we should uphold the practice. If it be taken to mean, as it generally does, three fully developed but separate blooms of the same age, we do not see the special advantage attaching to the number three. Mr. Mawley has no fault to find with the weather, recording the season as one exceptionally free from detrimental influences.

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 11.—What may be termed the New Year's Meeting of the Committees of the Royal Horticultural Society took place on Tuesday last in the Drill Hall, James' Street, Westminster. A beginning for the year was made, and a satisfactory one, for it was not expected that the capacity of the building would be tested on this occasion, though this may very possibly be the case at the next meeting. The display on Tuesday last was made up in large measure by two extensive collections of Chinese Primroses, and two groups of Cyclamens, all of which were commendable from the standpoint of quality, and they presented a very gay picture indeed. Orchids and other plants were not numerous, but a pretty group of ornamental foliage and flowering plants was present. Not a single Certificate or Award of Merit was recommended by the Floral Committee, and but one by the Fruit Committee. There was a collection of Apples from an amateur, and a number of dishes of Apples in competition for the prizes for flavour. Three Certificates were awarded by the Orchid Committee. At 3 o'clock a meeting was held for the election of new members to the Society, when a large number of names were submitted and duly elected.

Floral Committee.

Present:—W. Marshall, Esq. Chairman, and Messrs. Jno. Laing, H. B. May, R. Dean, Chas. T. Drury, J. H. Fitt, J. F. McLeod, Jas. Hudson, Jas. Walker, J. T. Bennett-Poë, J. D. Pawle, Chas. E. Shea, Chas. E. Pearson, Geo. Gordon, Edwin Beckett, Chas. Blick, Harry Turner, Geo. Paul, and Jno. Fraser.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, Chelsea, exhibited sprays of the Witch Hazel (*Hamamelis arborea*), and a paler coloured flowered one name *H. japonica* Zuccariniana; also beautiful sprays of *Garrya elliptica*, and a lovely collection of flowers from their hybrid greenhouse Rhododendrons.

A collection of Primulas from Messrs. H. CANNELL & SONS, Swanley, Kent, quite filled a side of one of the large tables, with nice plants in 5 and 6-inch pots. Eynsford Red and Cannell's Pink, both well-known and popular varieties, were shown. Duchess of Fife, with Fern-like foliage, and fine pink flowers, with yellow eye, is very pretty. Swanley Yellow is a variety in which the yellow eye extends unusually over the flower, and is as near being yellow as any we have noticed. Distinction is a good rosy-crimson flower. Emperor Improved, a magnificent carmine-pink, with plain foliage. Swanley Blue, also with plain foliage, very prettily serrated, is effective among the other colours. White Perfection was well flowered, and the blooms stood boldly above the strong Fern-like foliage. My Favourite is a pink variety, as is Pink Queen. The colours in all of them were bright and pure. In addition to the above, Messrs. Cannell showed some fine plants of the old double varieties, such as Earl

Beaconsfield, Annie Hillier, King of Purples, Mrs. R. Crabbe, Marchioness of Exeter, &c. (Silver Flora Medal).

Mr. JNO. R. BOX, West Wickham and Croydon, made a great display with Chinese Primulas, furnishing at least half of one side of a long table with a collection of capitally-grown plants, most of them in 6-inch pots, and each carrying a couple of dozen or more strong leaves. The first show of blooms were just developed. Some of the different colours were named as follows: Carmine Queen, a Fern-leaved plant, with moderately deep carmine flowers; The Queen, also a Fern-leaved type, with strong flower-spikes, flowers opening white, afterwards assuming a pink-blush; Margaret, apparently a giant strain, with large, crimped flowers—white, shaded mauve, and a distinct eye. Marquis of Lorne, Fern-leaved type, rosy-magenta flower; Cannell's Pink, a beautiful variety, with abundance of pretty flowers; Emperor Fern-leaved, with carmine-pink flowers; White Perfection Fern-leaved, abundantly flowered, the petals crimped considerably; Wickham White; Rosamond, deep pink; Queen of Primulas, white-flowered, and plain foliage; Firefly, having rather small flowers of deep crimson; Wickham Beauty, one of the best shown—it has plain foliage and large, beautiful flowers, of delicate blush; Surprise, a Fern-leaved, carmine-flowered variety; and Princess Mary, white, were included. The cultivation was good, but the development of the foliage excessive, and the colours of the flowers were not so bright as when grown in the country (Silver Flora Medal).

MESSRS. SUTTON & SONS, Reading, showed strains of *Cyclamen persicum* (latifolium), which made a very gay display indeed. The plants were well flowered, and the blooms appeared well above excellent and prettily-marbled foliage. All the plants were raised from seeds sown twelve months ago, and no supports were needed. Vulcan, the darkest coloured of those staged, and Salmon Queen, attracted much attention; and a few blooms of Purple Queen, resembling a colour frequently occurring in Sweet Peas, were equally remarkable. A few monstrosities shown by Messrs. Sutton may be the beginnings of greater variation among *Cyclamens* than was expected. One of these had so many as ten petals (Silver Flora Medal).

Another collection of *Cyclamens* was exhibited by Messrs. HUGH LOW & CO., Bush Hill Park Nurseries, Enfield. The strains exhibited a nice variety of colours, all of them bright and distinct, and the flowers were of good form and large (Silver Banksian Medal). The very bright Carnation Winter Scarlet, which we have noticed before, was again shown by Messrs. Low.

MESSRS. JNO. LAING & SONS, Forest Hill Nurseries, London, S.E., contributed a very pretty group of miscellaneous foliage and flowering-plants, among which was noticed a plant of *Nepenthes mixta* ×, with fine pitchers. The plants generally were bright in appearance, well-grown, and of choice species (Silver Flora Medal). Messrs. J. LAING & SONS also exhibited a few plants of *Cordylina* (*Dracena*) excellens, a green-and-white-leaved variety, the variegation following the margins of the leaf, which is about 3 inches wide at broadest point, and 12 inches or more long; also a pretty narrow-leaved *Dracena* named Distinction.

Maranta Wingfieldiana, shown by Mrs. WINGFIELD, Amphil House, Amphil, is an effective decorative plant.

Mr. T. S. WARE, Hale Farm Nurseries, Tottenham, showed several pansful of *Narcissus monophyllus* (*Corbularia*) in bloom; also *Fritillaria oranensis*.

F. W. MOORE, Esq., Botanic Garden, Glasnevin, sent sprays of *Chimonanthus fragrans*; also flowers of *Iris stylosa* var. *Empress Elizabeth*.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. Jas. O'Brien (Hon. Sec.), De B. Crawshaw, H. Ballantine, W. H. Young, Henry Little, H. J. Chapman, T. Statter, T. W. Bond, E. Hill, J. Douglas, and S. Courtauld.

The uncertainty about the weather keeping mild, doubtless influenced some prospective exhibitors, with a consequent falling off in the number of entries.

Captain HOLFORD, Westonbirt, Tetbury (gr., Mr. A. Chapman), exhibited a very interesting collection, more than fifty varieties of *Cypripedium*, testifying alike to their usefulness as winter flowers, and to the good methods of cultivation followed at Westonbirt. Of some varieties there were several flowers. We noted *Cypripedium* × *Statterianum* (*Spicerianum* × *vexillarium*), with its large bright rose-coloured upper sepal quaintly folded back; a fine variety of *C. × radiosum*, a very handsome set of forms of *C. × Leeatum*, *C. × Niobe*, and *C. × Niobe superbum*, the latter having a very fine rose-purple-veined upper sepal; a showy set of varieties of *C. insigne*, remarkable among which were *C. insigne* Unique, a very distinctly marked flower; and *C. i. citrinum*, with clear yellow and white flowers of the *C. i. Sanderianum* class; *C. × Pitcherianum* Williams' var., a massive and well-formed flower; a pretty hybrid between *C. × insigne*, Chantini and *C. Boxalli*, some very handsome *C. Charlesworthi*, *C. × oenanthum superbum*, *C. × Sallieri Hyeanum*, and in addition several brightly coloured *Selenipediums*, and some fine sprays of richly-coloured *Laelia autumnalis* were shown. The stand was awarded a Silver Banksian Medal.

Messrs. F. SANDER & CO., St. Albans, showed *Cattleya Trianae* Sander, a charming variety with finely-formed flowers, the sepals and petals of a delicate pearl-white, the front of the lip of a rich, dark, velvety purple (Award of Merit); also *Laelia anceps atro-rubens*, a rather small but very dark rose-crimson variety, of distinct features; *L. a. Dawsoni*, *L. a. Sanderiana*, *L. a. Hilli*, varieties of *Cypri-*

ium × Calypso, and Lycaste Skinneri, Dendrobium monsoniae, and D. × Dulce, Oakwood variety.

Messrs. HUGH LOW & Co., Clapton, staged a group in which the central plant was the new *Cypripedium* × *F. S. Roberts*, a hybrid of *C. niveum*, but the other species used not known. In general appearance it somewhat resembled × *Cowleyanum* (niveum × *Curtisii*). The flower is white, with rose-coloured flush, and dotted lines on the upper sepal petals, and a clear rose-purple tinge on the face of the (Award of Merit). Messrs. Low also showed a light form *Odontoglossum Wilckeanum*, some good *O. crispum*, *O. alli*, *O. Andersonianum*, *Cypripedium* × *Lathamianum*, × *Bellona*, &c.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr., Mr. S. Stoke), showed *Laelia anceps Amesiana*, Crawshay's var., distinguished from the original by its broader petals; the inner bases, and brighter purple tips to the sepals and petals, and especially by the side-lobes of the lip being marked with similar dark claret-crimson colour to the front-lobes (Award of Merit).

C. L. N. INGRAM, Esq., Elstead House, Godalming (gr., Mr. T. W. Bond), showed *Cypripedium* × *Magnet* (insigne *lambertii* × *Boxalli*), a fine flower of the *C. nitens* class, the upper sepal being handsomely spotted with chocolate-brown on the lower part, and purple in the upper half, the tip being pure white.

FRED. HARDY, Esq., Tyntesfield, Ashton-on-Mersey (gr., Mr. Stafford), again showed a plant of *Cypripedium insigne* under a name, about which some doubts had been raised. The committee agreed that it was the true variety. Mr. Hardy also showed *Cypripedium* × *Calypso*, and *Odontoglossum Andersonianum*.

ISAAC CARR, Esq., Poolemeade, Tiverton-on-Avon, showed some darkly-coloured hybrid *Cypripediums*; and F. A. EHDER, Esq., The Avenue, Gipsy Hill (gr., Mr. Morris), showed *C. × Rehderianum* (*Savageanum superbum* × *purpuratum*), a very neat flower, in which the fine rose-purple colour of the upper sepal was very attractive.

F. W. MOORE, Esq., Glasnevin, sent cut flowers of *Masdevallia chlorodiana*; and FRAU IDA BRANDT, Zurich (gr., Mr. Schlecht), cut spikes of *Laelia autumnalis* and *Aerides andarum*, the latter being grown in a cold house.

At the meeting, the coloured drawings of the Certificated plants of 1897 were submitted to the scrutiny of the members of the committee, who expressed their approval, and passed resolution to continue the work.

Fruit Committee.

Present:—Philip Crowley, Esq., Chairman; and Messrs. Geo. unyard, Jos. Cheal, A. F. Barron, T. J. Saltmarsh, Alex. Dean, J. W. Bates, W. Farr, C. Herrin, W. J. Empson, Geo. Lythes, H. Balderson, F. Q. Lane, G. Norman, J. Willard, W. H. Fife, and Jas. H. Veitch.

A collection of Apples and Pears embracing thirty dishes, as shown by Mr. W. J. Empson, gr. to Mrs. WINGFIELD, Amphill House, Amphill. This was a praiseworthy exhibit, and some of the varieties were very well preserved. Of Apples we noticed Lord Derby, Mere de Ménage, Cox's Pomona, Warner's King, Beauty of Kent, Lane's Prince Albert, Ribston Pippin, King of the Pippins, Gascoignes' Scarlet, Brownlee's Russet, Cox's Orange Pippin, &c. (Silver Knightian Medal).

A magnificent exhibit of Grapes was made by Mr. J. BURY, Petersham Vineries, Byfleet, Surrey, including six baskets packed for transit to market, the Grapes being attached round the sides of cross-handled baskets, and the surface protected by bent shoots. Altogether there were about sixty bunches, representing the varieties Muscat of Alexandria, Alicante, and Gros Colmar. The Alicante was specially well coloured (Silver Knightian Medal).

A large boxful of excellent Mushrooms from Mr. J. Miller, gr. to Lord FOLEY, Ruxley Lodge, Claygate, was awarded a Cultural Commendation.

In the Veitchian class for competition in flavour there were again a good number of Apples shown. The best Apple was Margil, shown by Mr. J. C. TALLACK, gr., Livermere Park, Bury St. Edmunds. The fruits were taken from an old orchard tree, growing in a sandy loam. Claygate Pearmain was awarded 2nd prize, and it was shown by Col. GRAYMER, M.P., Ilington House, Dorsetshire.

The best Pear proved to be Josephine de Malines, shown by Capt. CARSTAIRS, Welford Park, Newbury (gr., Mr. C. Ross). The fruits in this case were taken from a tree thirty-six years old, growing against a wall with south-west aspect; soil, a light loam or gravel.

Messrs. T. F. RIVERS & SON, Sawbridgeworth, showed their new black Grape Directeur Tisserand, a bunch of well-preserved Mrs. Pearson Grapes, and four very large Citron fruits.

A 1st Class Certificate was awarded to Pear President Barabe, from Mr. W. ALLAN, Gunton Park Gardens, Norwich. It will be remembered that on the last occasion an Award of Merit was recommended to this Pear, and it obtained 1st prize for flavour.

Mr. THOS. ROCHFORD, Turnford Hall Nurseries, Broxbourne, showed a new black Grape, said to be a sport from Black Alicante. The berries are large like Gros Colmar, with skin more like Alicante. The Grapes had very little flavour. The Committee would like to see the variety again after the port has been got upon its own roots.

DEVON & EXETER GARDENERS'.

JANUARY 7.—The annual supper of this Association took place on the above date at the Castle Hotel, Exeter. Mr. W. HARTLEY, gardener at Wonford House, in the chair. The company, consisting of members and friends, were rather

The chairman, in proposing "Prosperity to the Association and its work," spoke of the high level of excellence to which many of the essays given had reached, and the instructive discussions which generally followed their readings, thereby not only bringing out the different methods of cultivation practised, but, by comparison and inferences drawn from the results, pointing out which was the best. Mr. W. Mackay (Hon. Treasurer), in replying for the Society, said the members had good reason to be pleased with the work done in years past, and good grounds for hoping that yet better work would be done in the future.

CHISWICK GARDENERS' MUTUAL IMPROVEMENT.

JANUARY 6.—A meeting was held in the Council Chamber of the Royal Horticultural Society's Gardens of the above society, when Mr. A. DEAN gave a lecture entitled "Edible Stem Plants." There was a large attendance of members. Most of Mr. Dean's remarks alluded to were of a practical nature, and proved very interesting to his listeners, dealing, as they did, by the aid of diagrams, with Asparagus, Celery, Seakale, and others of that type, and giving full instructions as to cultivation. A good discussion followed, taken part in by several gentlemen present.

GRAND YORKSHIRE GALA.

Annual Meeting.

JANUARY 7.—The annual meeting of the guarantors and life members of the Grand Yorkshire Gala was held at Harker's Hotel, York. Ald. Sir JOSEPH TERRY occupying the chair.

The Chairman, alluding to the gala in June, said that circumstances had prevented the public witnessing the usual beautiful floral exhibition. He believed the flower-show would have been of an exceptional character, and one which would have been immensely appreciated. A strong wind, however, on the morning of the fête wrecked the flower tents, and rendered all the perfected arrangements but work in vain. The damage done amounted to about £600, a catastrophe which had never been previously experienced. On every hand the circumstances had created regret. Expressions of sympathy had been received from several of the exhibitors, and one gentleman—Mr. ATKINSON, of Sheffield—had sent a donation of five guineas to the Society. As regarded the coming fête, they had again made satisfactory arrangements with the Bootham Asylum authorities.

Ald. Sir CHRISTOPHER MILWARD proposed the re-election of Sir Joseph Terry as chairman of the council. The other officers appointed were:—Treasurer, Mr. Joseph Wilkinson; secretary, Mr. C. W. Simmons; and auditors, Messrs. Pearson and Taylor. The usual committees were also elected.

The following grants were made for the ensuing gala:—Floral arrangements, £650 (including £50 as a Victorian commemoration prize, offered last year but not awarded); music, £200.

Ald. PURNELL proposed the health of Sir Joseph Terry, and congratulated him upon having attained his seventieth birthday. No gentleman, he said, was more esteemed in the city. Ald. Sir JOSEPH TERRY suitably responded, and the proceedings terminated.

[Since this report came to hand, we greatly regret to have received intelligence of the death of Sir Joseph Terry, on Wednesday, the 12th inst. The deceased gentleman was for many years a zealous patron of the society, and of horticulture generally.]

ROYAL BOTANIC.

JANUARY 8.—A meeting of the Fellows of this society was held in the gardens at Regent's Park on Saturday last, Major Cotton presiding. Two new Fellows were elected. The chairman stated that he was pleased to be able to congratulate the Fellows upon the excellent position in which the society now stood as compared with its position at the opening of last year. At that time the outlook was gloomy, for the lease of the gardens was about to expire, and an accumulated balance of some thousands of pounds stood on the wrong side of the accounts, and was not only in itself a source of some uneasiness, but also prevented the society from giving prizes at the various fêtes and shows as liberally as it is desired. The position, however, had been resolutely faced, and he was pleased to say that with the co-operation of the Council and some of the leading Fellows, the society was now perfectly solvent, and the accumulated debt which had so long been a source of trouble and anxiety had been swept away. A new lease for the maximum term of thirty-one years had been promised by the Commissioners of Woods and Forests. Not only were the gardens open for study to the pupils of the various medical schools, but a school of practical gardening had been started with the concurrence and aid of the London County Council. The Middlesex and Herts County Councils had approached the Society with a view to sending students to the new school, and it was believed that to ladies also such an opportunity of learning gardening would be most agreeable. The Council of the British Astronomical Association, too, were taking steps to erect and equip an observatory in the gardens. Reference was made to the great increase in the number of Fellows elected in 1897, there having been more than eighty above the average

numbers of the last ten years. The receipt of a large number of donations to the library and museum was recorded, and a vote of thanks to the donors having been passed, the meeting terminated.

READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

JANUARY 10.—The annual general meeting of the Reading and District Gardeners' Mutual Improvement Association was held in the Club Room, "British Workman," on Monday last, when Mr. C. B. Stevens presided over a good attendance of members.

The report and balance-sheet read by the hon. secretary, Mr. James Pound, Jun., were of a very satisfactory nature, both showing that the Association was in a very flourishing condition. The committee regretted the death of Mr. Alfred Sutton, who had always taken a great interest in the work of the Association, and had since its formation in 1888 provided gratuitously the Club Room for their meetings. They also record the death of Mr. George Palmer, who was an annual subscriber from the commencement of the Association. The meetings during the year had been well attended, on some occasions upwards of eighty members being present.

A beautiful group of well-grown Cyclamen was shown by Mr. W. Townsend, The Gardens, Sandhurst Lodge.

SCOTTISH HORTICULTURAL.

JANUARY 11.—The annual business meeting was held at Edinburgh. Mr. M. TODD, the president of the Association, preside over a large attendance. The report of the secretary spoke of the success which had attended the efforts of the Association, both in its literary work and the influence it had brought to bear in cultivating the tastes of the general public in a love for horticulture in its higher branches. From its foundation in 1877, the Society each year had shown a large increase in membership, which had been the means of establishing the Association on a sound financial basis. The first minute of the Association showed a membership of 100, while at present there were 600 members, 150 new members having been elected during the past year. The report concluded by referring to the Chrysanthemum show which had been held under the auspices of the Association. The surplus profits of the show (£250) had been allocated to charitable purposes, as follows:—£100 to the pavilion fund of the Edinburgh Royal Infirmary, £50 to the Sick Children's Hospital, £50 to the Gardeners' Orphan Fund, and £50 to the Gardeners' Royal Benevolent Fund. The treasurer's report, which was also submitted, showed that the income from the Chrysanthemum show had been £1264 7s. 8d., and the expenditure, £1189 6s., giving a balance to the Association's account of £75 1s. 6d., to which had to be added the income of the Association proper, £88 19s. 2d., giving a total of £164 0s. 10d. The following office-bearers were elected for the ensuing year:—Honorary President, His Grace the Duke of Buccleuch; President, Mr. M. Todd; Vice-Presidents, Mr. D. P. Laird and Mr. James Grieve; Secretary, Mr. R. Laird, 17A South Frederick Street; Assistant Secretary, Mr. Murray; and Treasurer, Mr. Alexander Mackenzie.

Obituary.

MICHAEL LAURENCE.—The death is announced of Mr. Michael Laurence, who since 1847 has been the head of the flower gardens at Tostock house, Suffolk, the charming seat of Mrs. William Gilbert Tuck. Although more than eighty-two years of age, he remained hale and active until the last, and was rarely absent for a day from his work. No matter what season, wet or dry, he always had a wonderful display of hardy flowers in spring, summer, and autumn. Only last November, when looking round, we noticed over 100 plants of various kinds in bloom. He was no lover of formal beds of glaring colour and prim form, but delighted in the better class of annuals and perennials to relieve the more formal class of bedding-plants. Perhaps as a grower of Pansies, Auriculas, Primulas, and Dahlias, he had few equals, and as a good all-round man, his employers have certainly lost one of the best. A large number of persons from all parts of East Anglia attended his funeral on Friday last at Tostock Church.

MAX DEEGEN.—Many Dahlia cultivators in this country will learn with regret of the death, at Köstritz, in Thuringia, of Herr Max Deegen, at the age of fifty-six years. He was the second son of the Dahlia raiser, Christian Deegen, of Köstritz. M. Deegen followed his father's profession, at first in his nursery at that place; and afterwards travelled in search of knowledge and experience. He returned after several years, and took over the management of his father's nursery, and in 1870 he started an independent

business as florist, but chiefly as a raiser of Dahlias, and it is to his efforts in this direction that we owe many of our most beautiful varieties. The business will continue to be carried on by his eldest son, Adolf Deegen.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named: and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending January 8, is furnished from the Meteorological Office:—

"The weather during this period was very unsettled and mild over the Kingdom as a whole, with frequent and considerable falls of rain in all the western districts. Over the more eastern and southern counties, however, the rain was as a rule, less frequent and heavy, and several intervals of clear bright weather were experienced.

"The temperature was above the mean, the excess ranging from 1° in 'Scotland, N.,' and 2° in 'Scotland, E.,' to 5° in most parts of 'England,' and to 6° in 'England, S.' The highest of the maxima were recorded about the middle of the week, and ranged from 56° in 'England, E.,' and 55° in 'England, S. and Ireland, S.,' to 49° in 'Scotland, N.' The lowest of the minima, which were registered on rather irregular dates, ranged from 23° in 'Scotland, N. and E.,' and 28° in 'England, E. and S.W.,' to 35° in 'England, E.W.,' and 36° in the 'Channel Islands.'

"The rainfall exceeded the mean in all the 'Grazing districts, as well as in 'England, N.E. and E., and the Midland Counties,' the excess being very large in 'England, N.W. and Ireland, S.' In 'Scotland, E., England, S., and the Channel Islands,' it was less than the mean value.

"The bright sunshine was somewhat in excess of the mean in most of the northern, eastern, and southern districts, but below or just equal to it in the west. The percentage of the possible duration ranged from 26 in 'England, S. and the Channel Islands,' to 12 in 'Ireland, N.,' 10 in 'Scotland, W.,' and 9 in 'Ireland, S.'"

TRADE NOTICE.

MR. HENRY WOLLCOOK, as Manager at Posbrooke Gardens, Titchfield, Hants.

ENQUIRY.

"He that questioneth much shall learn much."—BACON.
WILL any reader of this Journal kindly tell "H. C. J." the name and address of the makers of the Cheltenham Garden Engine (Page's Patent).

GARDENING APPOINTMENT.

MR. THOMAS PHILLIPS, for nearly three years Head Gardener with the late F. LATOUCHE, Esq., at Bellevue, Delgany, co. Wicklow, has been appointed Head Gardener to C. TWYSDEN HOARE, Esq., Bignell House, Bicester, Oxon.

MR. THOMAS E. BINDALL, for the past seventeen years Gardener at Langton Hall, Northallerton, and Sandley, Gillingham, Dorsetshire, as Gardener to S. G. LEATHAM, Esq., Hemsworth Hall, near Wakefield.

J. CLAYDON, late Gardener to Captain JOLLIFE, Heath House, Petersfield, Hants, as Head Gardener to Major GUNDERY, R.A., Purbrook Park, Cosham, Hants.

BOOKS: *G. Broad, Junr.* A manual on the cultivation of the Dahlia is sold by Dobbie & Co., Rothesay, N.B., also by Messrs. Macmillan & Co., London.

CUPRESSUS LAWSONIANA AND C. (RETINOSPORA) PISIFERA: *M.* Detached sprays are often difficult to distinguish. Generally the leaves of Retinospora are more suddenly and abruptly spine-tipped, and flatter than in C. Lawsoniana. The cones in the latter show the tips of the bracts more clearly than do those of the Retinospora. But if you are handling them every day you will soon get to know them much better than those who only see them occasionally.

EUPHORBIA JACQUINÆFLORA: *Anxious.* Cut up the ripened parts of the stems into lengths of 9 to 12 inches. This should be done when the plants have gone out of flower, and have been kept dry for ten or twelve days. They may be struck singly in well-drained pots filled with sandy-peat; or, better still, half-a-dozen together in a 48, in bottom-heat. These potfuls of rooted cuttings may be planted out in a border in a stove, or repotted without separating them one from the other, the effect of the whole, when in flower, being superior to that afforded by single plants. It is a plant that wants a good deal of rooting-space, and a hot, sunny place in which to grow at all times. Nice bushes are attained by stopping the points once or twice; and, although there will then be more flower sprays, these will be small. The best kind of soil for Euphorbia Jacquinæflora is a rich, sandy peat; and as a good deal of water is required by the plant in the summer, sufficient space should be left for affording it, and plenty of drainage is very necessary.

GEOMETRICAL DRAWING: *Bucks.* A manual is, we believe, published by Mr. Upcott Gill, Bazaar Office, 171, Strand, W.C.

NAMES OF FRUITS: *A. O.* Specimen not a good one, but probably Cox's Pomona.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*R. L. N.* Probably a seedling Quercus Ilex.—*P. M. M.* Dumbarton. The Orchid is Oncidium Jonesianum. The plant is found generally to thrive best on a bare block or raft, and its natural habit of growth is for the thick terete foliage to hang downward. When making new growths, you can scarcely give it too much heat and moisture; but while flowering a cooler house suits the plant better, and prolongs the duration of the flowers. The house you have it in will probably suit it for the greater part of the year.—*J. M.* Hypericum Androsæmum.—*C. B.* 1, Pteris cretica albo lineata; 2, Pteris serrulata; 3, Pteris Ouerardi; 4, Pteris serrulata cristata; 5, Pteris cretica cristata; 6, Pteris tremula.—*A. D. L.* Catsetum macrocarpum.

PETUNIAS FROM SEED SOWN IN A COLD VINERY: *J. A. S.* The plants can be raised in a cool vinery, provided the seed be sown thinly in pots or pans filled with light, slightly sandy soil, and covered till germination has taken place with a tile or piece of glass. When the seedlings are above-ground, bring the seed-pot close to the glass, affording it a slight amount of shade when the sun is shining. Prick out the plants when they are half-an-inch high.

POINSETTIA PULCHERRIMA: *Anxious.* From the present time, or when the flowers fade and the foliage begins to turn of a yellow colour, withhold water, but still keep the plants in a moderately warm house, and when quite at rest, store them in any dry shed out of reach of frost. Cuttings may be made of the leafless ripe shoots cut into 6 to 9-inch lengths, and struck singly or several together in well-drained pots filled with very sandy loam, and then afforded a gentle watering. The pots may be stood in a hot-house till rooted, being careful not to afford them much water till roots form. When potted off, the plants should be put into a warm pit near the glass, and shaded till established, but not afterwards. Very little artificial heat is required during the summer months. Old plants may be started into growth after flowering, without affording them any rest, the young shoots being taken off with a heel, and used as cuttings. These may be 6 inches long. To prevent bleeding, place the cuttings round the sides of a deep pot, the butt ends upwards just ranging above the rim, fill with damp warm sand, and leave them therein for twenty-four hours in a warm house, by which time the milky juices will have hardened where exuded. They must be struck in propagating-pit or hot-bed, and kept close, the leaves being tied up to small sticks. The treatment after rooting is the same as that given above.

PRIMULA OBCONICA: *C. M. I.* In the absence of any particulars of cultivation we cannot account for the browning of the edges of the leaves. It is doubtless some little point in culture; and we note that the leaves are deficient in substance.

TREES AND SHRUBS: *G. W.* For exceptions as to what rabbits will not eat, see "Answers to Correspondents" in *Gardeners' Chronicle*, for Jan. 8.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,

MORE THAN DOUBLED, and that it continues to increase weekly.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

(For Markets see p. xiii.)

THE

Gardeners' Chronicle.

SATURDAY, JANUARY 22, 1898.

DO ORCHIDS DEGENERATE?

SINCE the very interesting article appeared on the above subject in the pages of the *Gardeners' Chronicle* of September 18 last, I have been somewhat disappointed in finding the hope expressed by the writer that the readers of the *Gardeners' Chronicle* might be "able and willing" to give their version of a matter of such great importance has been but partially realized, only a limited number of contributors coming forward with their experiences. The few papers that have appeared, however, are valuable, the most so, I venture to think, in partly affording a direct answer to the question, being the plain unvarnished list of Orchids furnished by Mr. W. H. White, from Sir Trevor Lawrence's collection, which appeared in the *Gardeners' Chronicle* of Oct. 2 last. Surely this list tends to prove that, under proper treatment, Orchids in this country do not degenerate.

It is something to say that out of some 250 species enumerated more than fifty of the plants have been in cultivation for the past twenty years, and considerably over 100 for the past fifteen years, and all are, presumably, at the present moment in robust health. It must also be remembered that many of the species in this list fall under the heading of the "unmanageables." In putting the question: Do Orchids degenerate? I take it that what is meant is, do the plants gradually, and year by year, decline in vigour after importation, even when treated in a rational manner, and when grown under conditions as nearly as possible similar to those under which the plants are found flourishing in their various natural habitats. I have never had the pleasure of inspecting Sir Trevor Lawrence's famous collection, yet I am inclined to the belief, that in its cultivation attention is paid to the reproduction, as far as possible, of those natural conditions under which the plants flourish in the various climes from which they are procured, and therein, to a very great extent, lies the secret of success. If this be so, then, I think, it may be said that we are approaching, at least, the final answer to the question, Do Orchids degenerate?

Mr. T. Simcoe, in *Gard. Chron.*, Oct. 16, 1897, p. 275, gives two causes for degeneracy in Orchids grown in England, viz., the ravages of yellow thrip, and our trying British winters. Some winters are trying, no doubt, but at the worst they can only check the growth and vigour of Orchids for a limited period, and a style of house may yet be invented to put an end to this drawback. Besides the above, numerous other causes might be assigned for

degeneration in Orchids of a like character, but is it not idle to take these matters into consideration at all? If we are to consider them, then it may in truth be said that nearly the whole of our cultivated plants are in a state of degeneracy, as nearly all suffer more or less from the attacks of insects and the vicissitudes of our climate.

I take it, however, that all this has nothing to do with the question at issue, namely, "Do Orchids degenerate in England when cultivated under circumstances most favourable to their health and longevity, and in consideration of the natural conditions under which they are found to flourish in a wild state?" It is obviously a waste of time to write about yellow thrip, crowding, unsuitable potting-material, &c., as causes of degeneracy, because all these are inimical to the health and longevity of any plant in cultivation. In conversation lately, I was given the familiar example of the Potato; but is, after all, the frequent failure of this crop to be attributed to degeneracy? Let those who wish an answer to this query remember that the Potato has been in cultivation in Britain for the last three centuries, and now at the end of that long period, witness the displays of the different varieties of the tuber, and then say if the Potato has or has not degenerated? methinks if the exhibition examples of the present day could be compared with the first importation of the tuber by Sir Walter Raleigh, the question of degeneration would very soon be lost sight of. Disease is not degeneracy. The first can be combated, the second cannot. I may be told that but for the raising of new varieties from seed the Potato would, at the present day, be unknown in England. Possibly, but the battle has been fought against disease, not against degeneracy. I therefore consider that most excellent and valuable advice has been given in that part of the paper in the *Gardeners' Chronicle* of September 18, in which the writer says, "The question is, then, would it not be wise to raise uncrossed, or true, many of the finer varieties of Cattleys, Lælias, and other popular Orchids, and thus while increasing the plants wished for, get also the better constitution which comes with the seedling plant raised in the country in which it has to grow?"

I am strongly of the opinion that failure in Orchid-growing results, in most cases, from a total lack of knowledge of the various climatic conditions which prevail in the regions from which the imported plants are drawn, and the conditions under which they flourish and blossom in their native wilds. To one who has seen Orchids growing in their native wilds it is a grievous thought to know of the vast numbers of these plants that are annually torn from the Orchid forests of the world, brought to the hammer in England, and from want of knowledge and other causes, allowed to perish and be thrown to the rubbish-heap. Let any one look at the weekly notices of auction sales of Orchids which appear in the *Gardeners' Chronicle*, and then ask the question, What becomes of all these plants of which the jungles of the world are robbed year by year, and sent like ordinary merchandise to our markets? Are they all cared for, and do they all find suitable quarters for the reproduction of that beauty and sweetness erst so lavishly wasted "on the desert air?" Perhaps, if all the truth were known, the answer would be—not a tithe of these are given a chance to renew that beauty and fragrance, but are doomed to decay and death at no distant date from their first arrival on our inhospitable shores. If ever it be found

necessary to legislate against the indiscriminate and wholesale destruction of any plant, let that plant be the Orchid. I am aware that England is not mistress of all the Orchid-producing countries of the world, but many of her colonies and possessions abound in these plants, not a few of which are of the rarest beauty and value, and which she has the power to protect and save from total extinction.

To my mind, the most interesting and suggestive passage in the article in the *Gard. Chron.* of Sept. 18 last, already referred to, is that in which the writer says that to redeem many evergreen Orchids from the list of unmanageables, probably more attention must be paid to the all-important matters of rest and moisture, for "an excess of heat and moisture at a season when, though evergreen, they require, in the same manner as the deciduous plants coming from the same districts, a resting season, though not necessarily a drying-off."

A more valuable suggestion than this, I venture to think, could hardly be offered, and in support of it, I may be allowed to give my experience of the conditions under which Orchids both evergreen and deciduous are found growing in their native habitats, which though circumscribed, may yet be of some little value to the reader.

The following observations are confined to what I noticed on the plains and hill-tracks of Malabar, in Southern India, where I sojourned for several years. I have no experience of other districts or countries, so that whether the conditions under which the two typical plants are found in other quarters of the globe are the same I will leave others to say.

Evergreen Orchids in Malabar are generally found from the coast level up to an elevation of say 3,000 feet; from 3,000 feet up to 5,000 feet deciduous Orchids are found, and from 5,000 feet up to the summit of the highest mountains evergreen Orchids are again found. There are thus three distinct zones, the plants of the one never encroaching upon that of the other. Of course there must be a cause for this, and so far as I am able to judge it is as follows. J. Lowrie.

(To be continued.)

KEW NOTES.

LOBELIA INTERTEXTA, Baker.—This is a new species of Lobelia which has lately been received from British Central Africa, where it grows at an elevation of about 2000 feet on the Zomba hills, and is described as "a very pretty species, wonderfully free-flowering, generally at its best under the shade of rocks." It has the habit of *L. erinus*, the bedding Lobelia, but is looser, the stems and under-side of the leaves are purple and hairy, the latter being spatulate, crenate, and half an inch in diameter. The flowers, which are in loose terminal racemes, are on slender stalks 1 inch long, and they are of the usual shape, half an inch in diameter, coloured bright lilac-blue, with a white central area, and a pair of eye-like spots on the lower segments. The Kew plants were raised from seeds sown last spring, and they have flowered freely and continuously since November, the poisonous fogs experienced about Christmas time having no apparent effect upon them. I believe this will prove a useful pot-plant for the greenhouse in mid-winter, and it is also likely to be useful as a bedder. A figure of it has been prepared for the *Botanical Magazine*.

KNIPHOFIA PRIMULARIA.

Plants of this handsome new yellow-flowered species are now flowering freely in the temperate-house at Kew. It was received from Herr Max Leichtlin in November, 1894, who wrote "I beg to send you a new *Kniphofia* which came from Natal, and is a winter-bloomer. The leaves are 3½ to 4 feet

long, and the scapes are a yard high. It is a graceful plant. Perhaps Mr. Baker will be good enough to name it when it flowers." In the following spring it was planted in the Bamboo garden, where it grew freely, but did not show for flower till November, consequently the flowers did not develop. Next year the plant was grown in a pot outside, and taken into the temperate-house to bloom. This it did in January last year, when Mr. Baker named it as above, and described it in the new volume of the *Flora Capensis*. Several examples of it are in flower now, and as the spikes are as strong, and the flowers as numerous and large as those of *K. aloides*, whilst their colour is a clear primrose-yellow, it will be seen that this is a useful addition to winter-flowering plants for the greenhouse. The flowers were uninjured by fog.

OXALIS CRENATA.

This plant has been recommended, and, I believe, tried as a substitute for the Potato in countries where the climate is unfavourable to the latter. It has fleshy stems about 2 feet long, and from the base of these in the autumn stoloniferous stems are developed, upon which are Potato-like tubers in large numbers. Plants grown in a bed in the open air at Kew produced a large crop, the largest being 2 oz. in weight. Raw, they are of a bright red colour, but when with cooking they change to a pale amber colour, they are quite as palatable as the Jerusalem Artichoke. Those I tried were boiled twenty minutes in water containing a pinch of carbonate of soda. According to Vilmoren, this is the "Oka" of the Peruvians, and is highly esteemed in Peru and Bolivia as a vegetable. The tubers when gathered are exposed to the action of the sun for a few days. They are planted in rows 3 feet apart, and are not dug until after the frost has destroyed the tops. Two varieties are cultivated in France, the yellow and the red. In my opinion this plant is worth a trial in the warmer parts of this country. The tubers are being distributed from Kew to likely stations in the colonies and India.

STRELITZIA REGINÆ.

There are two large healthy examples of this plant now flowering in the Mexican-house at Kew, where they are planted in a sunny position in a kind of rockery. One of the plants has eight and the other five spikes, each about 4 feet long, and bearing an orange-yellow and dark blue flower 6 inches long. For such houses as that named—indeed, for any warm or tropical stove of large size, this is an excellent plant, whether grown in a pot or planted in a border. In the same house with *S. Reginæ*, and also in flower, is a large specimen of *S. augusta*, which used to be in the "Palmarum" at Olympia before it came to Kew. The nearly-allied species, *S. Nicolai*, is in flower in the Palm-house. *W. W.*

ALPINE GARDEN.

NEW AND RARE PLANTS FOR ROCKERIES.

(Continued from p. 28.)

Astrantia major rosea is common in the alpine pastures above Montreux, and in the Alps of the Rochers de Naye. The involucre is pink, often carmine, and very showy. I transplanted some plants here into our common garden soil, and they kept their colour very well.

Campanula mirabilis, Alboff, was found by Mr. Nicolas Alboff, September 2, 1894, in a crevice of a limestone rock in Abchasia (Caucasus). He found only one plant of this marvellous *Campanula*, and we were fortunate enough, when he brought it to Geneva, where the dried specimen was placed in the Boissier Herbarium, to find some ripe seeds in two carpels, so that the species has been introduced into gardens. It is a beautiful plant, and M. Alboff was very enthusiastic in speaking of his discovery. It grew in a chalky soil, exposed to the full sun, and the one plant bore more than a hundred flowers. These flowers are very large, and belong to the group of the *Campanula medium*; they are of a very good lilac or light reddish-blue colour.

The peculiarity of the plant is in its root, which is very thick, and Carrot-like. The leaves are thick, of a very deep green colour, shining, glabrous, and very strongly ciliate at the margin. They are 4 to 5 in. long, $1\frac{1}{2}$ to $1\frac{3}{4}$ inch broad, and of a leathery texture. It has not yet flowered with us, but it flowered with my friend Mr. Max Leichtlin, at Baden Baden, who says it was a glorious thing. A good plate of it appeared in the *Bulletin de l'Herbier Boissier*, t. iii., where it was first described, and in the rare volume by Mr. Alboff, *Prodromus Floræ Colchicæ*.

Clematis heracleifolia, D.C., is a distinct and curious species, of which we got seeds from the University garden of Tokyo (Japan). The plants from these seeds are very similar to those of an old *Clematis* which was in this garden, then belonging to Mr. Paris, for more than thirty years without anyone knowing what it was, or being able to identify it. The plant is sarmentose, but not climbing; its branches $4\frac{1}{2}$ to 6 feet long hang from the rocks, or creep over the soil. The leaves are large, 9 inches long, and 8 broad, composed of five leaflets, of which the terminal is much larger than the others. They are dentate, and of a deep green tint, somewhat shiny. The flowers are very numerous, borne in large panicles, rather small, of the same form and size as those of *C. vitalba*, but of a light blue. They seed rarely here, and we have seldom gathered any ripe seed from our old plant; but the species can be easily increased by grafting. The profusion of the little bluish flowers in immense racemes from August till November makes the plant very decorative in the rock-garden. It grows in a shady or sunny position, and in any good soil.

Coprosma Pehi, Ch. [?], is a fine little Rubiaceous shrub creeping over the soil, and of the same appearance as *Azalea procumbens*. The seeds were sent to me from New Zealand, and gathered there 2200 feet up the mountains. The plant is hardy, but although our specimens are four years old, they have not yet flowered. I do not find any mention of it in the *Index Kewensis*.

Corokia Cotoneaster, Raoul, is another New Zealand shrub, which has proved hardy here, and of which we got seeds from the Southern Alps of New Zealand at 2000 feet altitude. Curious in growth, erect, with few and small cuneate leaves, white underneath, of spiny aspect, the shrub is more curious than beautiful, but suitable for rockeries.

Cotula squalida, Hook. f., and *C. pyrethrifolia*, Hook. f.—The former came from Otira Valley, Westland, in New Zealand (1100 feet); the second, from Mount Rolleston, Westland (4500 feet). Two nice little Composites, of which M. Cockayne sent us seeds five years ago, and which are very hardy. They are quite dwarf, creeping, growing exceedingly rapidly, spreading everywhere over the soil, and covering it with their pretty foliage, like a little Fern (*Asplenium fontanum*), although much smaller. The flowers are without interest, but the growth of the plants and their charming foliage give them value.

Dianthus Boissieri, Willkomm, was discovered by Boissier in the Sierra Morena (Spain), and is a large and curious form of *D. sylvestris*. The stem is often 2 feet high, and the flowers large and of a good carmine tint. It requires a sunny position.

D. graniticus, Jordan, from the south-west of France, is a very dwarf variety, growing in the fissures of rocks and sandy ledges of granitic formation in the Olive region. Flowers solitary, small, of a very good red colour. It requires a sunny position.

D. diutinus, Kitabel, from the Transylvanian Alps and the Banat, is a very rare plant, 16 inches high, with glaucous foliage, and a head of flowers of a very good pinkish-carmine tint.

D. gracilis, Sibthorp, is a small-growing plant, with thin and narrow leaves, with sturdy and sweet-smelling flowers, of a light rose colour. It requires a sunny habitat. It grows on Mount Athos, and in the Balkans.

D. microlepis, Boissier, has been found by Frivaldsky in the alpine regions of the Mounts Rilodagh and

Kalophr in Thrace, at an altitude of 7700 feet. It grows in Bulgaria, and I have got seeds of it from Rhodope. It is a very distinct species, quite dwarf, a kind of *Dianthus glacialis* in miniature. The flowers are of a good carmine-red, and we have also a white-flowered variety.

Dianthus pinifolius, Sibthorp et Smith, from the mountains in Turkey, Greece, and Wallachia. The seeds of it we have from Rhodope, and they yielded a very curious *Dianthus*, with narrow leaves of deep green, with small flowers in clusters, and borne on long stems. The corolla is pale carmine or rather lilac.

Dianthus spinosus, Desfontaines (D. Fontanesii, Boiss.), is a little bushy plant, very densely caespitose, glaucous, forming dense tufts, and not spiny—hence the name *spinosus* seems incorrect—but spiny in appearance and bearing white flowers, pink and agglomerated into small heads. It is a native of the higher Persian Alps. *H. Correvon, Geneva.*

THE ROYAL BOTANICAL GARDEN, BELFAST.

IRELAND is not particularly rich in public parks and gardens, but those actually in existence are remarkable for their quality, and for the richness and luxuriance of their hardy and exotic vegetation. At the head and front of such Irish gardens is Glasnevin, and no park in Europe can rival the Phoenix Park, Dublin, in its natural beauty, its primæval groves of Hawthorn, and its excellent keeping. In Dublin itself we have the St. Stephen's Green Park, the noble gift of Lord Ardilaun, with its greensward and pools, its plants, and its trees, and its unique collection of choice water-fowl, a veritable oasis in the midst of a great city, to which all have a welcome and free access, be they peers of the realm or a group of city arabs from the Coombe and other populous purlieus, bent on enjoying a tumble on the green grass, a frugal picnic with their tiny dark-eyed sisters amongst the birds and the flowers. From Dublin to Cork is a far cry, but the Queen's University Gardens at Cork are rich in choice plants, including a collection of species, varieties, and hybrids of the genus *Brownea*, not to be seen so well grown and flowered and fruited perhaps elsewhere. It is a treat to see the creeper-laden walls, and the garden there, where sweet Bays or Laurels flower and fruit as luxuriantly as in Italy; and many exotics not usually seen are to be found in the plant-houses, or even in the genial, open-air garden of this beautiful south country.

Not many weeks ago I paid a visit to "the cold black north" of Ireland with a garden-loving friend, who took me to Belfast, and some of its prettiest of public and private gardens. I had been previously under the erroneous impression that the Botanical Gardens at Belfast "were going down," and for many years back this had, I learned, really been the case; but there is now a vigorous and healthy renaissance, and the Belfast Botanical Garden and Park promise soon to rival those of other and even more favoured places. The beneficial reaction to which I refer began when the Corporation of Belfast acquired the garden on behalf of the citizens, who now flock to it by the thousand and tens of thousands on high days and holidays.

Although a town-garden in every sense of the word, it is nevertheless a most attractive and interesting place, with broad breadths of greensward, fine shade-trees, gay flowers in quantity at all seasons, and well-stocked and artistically-arranged plant-houses to boot.

Beside the main walk leading from the entrance to the conservatories are good examples of *Quercus Ilex* in variety, and other Oak-trees, including a good specimen of *Quercus suber*, *Q. austriaca semper-virens*, and one or two rare kinds, such as *Q. Fordii*, and *Q. fulhamensis*.

On my first visit, when looking at the trees, Mr. Smith, of Newry, pointed out to me on the lawn near the rockery, an old specimen of the large-leaved *Pyrus* (*Aria*) *majestica*—perhaps the largest leaved and most effective of all the geographical

as of the "White Beam" tree. *Betula populendula* is another rare and distinct tree here, grows freely, as one might naturally expect in northern land of Birch and Willows. As one sees Belfast, no tree-lover can fail to be struck with admiration at the graceful, silvery-stemmed birches, and the grey Willows by the burns or rivers.

In the broad grass-plot facing the old flower-garden and conservatories, there is one of the finest White Willows (*Salix alba*) I ever saw in a town or public garden; it almost reminds one of the gigantic Black Poplar in the time-honoured old Ducal Garden at Dijon, although now only a

although only recently completed. There are rocks and boulders in all positions and aspects, and the plants are doing well upon or near them. There is a drip-well and Lily-pools for these and other aquatics, and there is also an extensive pond or lake, the banks of which are to be graced with Japanese Bamboos and Maples, and with the great "Prickly Rhubarbs," or Gunneras, of Chili and Peru. Between the rock-garden and the lake there is a naturally-contrived "prospect-mound," an old and characteristic feature, well worth retaining or reproducing in gardens, whereas here there is really a use, or reason to be in its favour. Lying as the garden does down the side of a slope, this "Prospect Mound" secures

greens; but it is more than a dream, for the workers in the factories and dockyards of Belfast are alive now to the gentle spirit of the garden, and, as we have said, flock here with their children and their wives to see the flowers, or to stroll on the green turf under the trees, or to meander quietly through the conservatories, and to peep into what is certainly one of the finest and most artistically arranged of all the Fern-houses in Europe, or in the world. I have certainly never seen so fine and satisfying a collection of Ferns, Bamboos, mosses, and climbing or trailing plants under a glass roof before—and I have seen a good many glass-roofed gardens and conservatories, and ferneries, and winter gardens in my time.

FIG. 19.—CONSERVATORIES AND FLOWER-GARDEN, BELFAST BOTANICAL GARDEN. (SEE P. 50.)

little of its top growth or umbrage remains. The slanting trunk or bole is over 19 feet in circumference, and even still does not appear very disproportionate when its branches are clothed with its silver grey, or olive-like leafage. Standing alone in its glory on the close-shaven lawn it is popular in more ways than one, and in summer-time it is the favourite rendezvous for the children who sit, or play and chatter beneath its shade. It is well-called "The Children's Tree," and long may it flourish as a memento of the past, and as a beautiful example of the beauty and appropriateness and usefulness of a native tree, in what is now a very popular and enjoyable public garden.

An extensive and thoughtfully-planned rock-garden is amply worth notice, and is already well stocked,

many pretty peeps or views, not only of the Queen's College, Elmwood, and other spires or towers, but also of the "Black Mountain," and of the domain and woods belonging to Lord Derrymore. The tower of Queen's College, as seen through the trees is a charming feature, and recalls to mind, though in reality very different, the dear old Botanical Garden at Oxford, with its leafy foreground to the tower of Magdalen College. To think of Oxford and its gardens and walls, and cloisters, its "checkered Daffodils," or Fritillaries in the meadows, its river walks, and its song-birds, headed by that Queen of the night and of song the nightingale, seems like a dream in this city of towering chimneys and whirling looms—surrounded by flax-fields and bleach-

I may be wrong, but I think there is a charming bit of personality about this cool fernery. When our good and true fellow-craftsman, Dean Hole (now of Rochester) then of Cauntton, Notts, wrote that classical book on Roses, he used, or implied his feelings as to Rose culture in words something like these:—"He who would grow beautiful Roses in his garden must first of all have beautiful Roses in his heart." By the same token, I feel sure that the courteous director of the now most enjoyable Belfast garden must have had very dainty ideas of Fern beauty in his mind before he could possibly have planned and carried out under difficulties—or "through the fire," as he expressed it—such an exquisitely verdant, rocky glen as he has done in "the

garden that he loves" (with all due apologies to the Poet Laureate). I am not a geologist, but the neighbourhood of Belfast is a geologist's paradise, and there is a good deal of geology in Mr. Chas. McKimm's paradise of Ferns. The major portion of the rocky side-walls, banks, and borders on which the Ferns grow is soft red sandstone; there is limestone also for such species as delight in its influence, and there are sundry masses of quartzite, or silica shaped like pears, but like in the size to the old howitzer shells used at Sebastopol. There are rocks of many kinds—a charming, perfect column of basalt beside the door that is delightful to enter by, but depressing to leave, so fresh, cool, and delightful is the fairy-like Fern glades within. Our photogravures, figs. 19, 20, and 21, give an excellent idea of the place from their respective points of view; but there are twenty points of view, and nothing short of an album of photographs would give any adequate notion of the place in all its phases of light, shade, and colour.

Amongst the Tree-Ferns are *Dicksonia antarctica*, and *D. squarrosa*, *Cyathea dealbata*, and *C. petiolaris*, or *C. medullaris*, and others, the names of which I forget. There is a dense green bank of "Killarney Fern" measuring about 9 feet long by 3 feet broad, and as fresh and healthy as one could desire. I suspect that Mr. McKimm has more *Trichomanes radicans* now growing in the Belfast Garden than could be now found at Killarney. Beautiful and translucent as this choice and popular Fern is, and ever will be, I saw a charming pale green, crapey-textured variety here that I have never seen elsewhere. It is more crisped, and its pinnae are more frilled than in the type, and the pale, almost transparent pea or apple-green hue of the feather-like fronds lends to them a most exquisite appearance. To see the dainty filmy Ferns growing near or around the black velvety trunks of the *Dicksonias* was most effective, and an experience I shall not soon forget.

The great Tree-Fern stems were clustered all over with a warm brown fur-like growth of green-tipped living roots, and the effect of these was heightened by feathery *Retinosporas*, or by the slender wands and grassy leafage of *Bamboos*; while from the roof depended the rich crimson flowers of that best of all the *Tacsonias*—*T. exoniensis* ×. On all sides are mosses, *Lycopods*, creeping *Ficus*, *Tradescantia*, and *Begonias*, revelling in a temperature and an atmosphere that must be delightful to them in all ways.

Foliage-plants and Ferns are quite a specialty, and Mr. McKimm having at times a large amount of decorative-work on hand, has adopted the use of moveable screens, made of wood-framework faced with cork and fresh green moss, either *hypnum* or *sphagnum*, in which Ferns and other small-growing or creeping plants are effectively grouped and planted. On ordinary occasions these screens hide the hot-water-pipes in the plant-stoves or conservatories, but they can be removed anywhere at a few moments' notice. The idea was a novel one to me: hence, I mention it here for the benefit of all whom it may happen to concern.

Another little wrinkle in Fern-culture adopted by Mr. McKimm is not only to give suitable stimulating manure to his plants, but now and then a good soaking of lime-water is given, and is found to exert a very beneficial effect on Ferns generally, but especially on the *Adiantums* or *Maidenhair Ferns*.

Beautiful and satisfying as is the fernery, we must push on to the other houses, and in passing admire two fine masses of rosy-plumed *Pampas-grass* in the flower-garden. There is an extensive range of iron-houses filled with healthy and well-grown stove and greenhouse flowering and foliage-plants. The Chinese Banana is fruiting freely, and there are plants of economic interest, such as African Rubber (*Landolphia*), *Coca* (*Erythroxylon Coca*), *Croton*, *Ricinus*, *Strychnos*, Arabian and Libe-rian Coffee, Tea, *Coca*, Cuba Bast, *Arnatto* (*Bixa orellana*), the "Upas-tree" of Java and Borneo, and many other interesting things. In one of the private plant-stoves I saw a strong and healthy plant of Mr. Ellis's "Water Yam," of Madagascar (*Ouvirandra fenestralis*), and a healthy specimen of the graceful *Asparagus comorensis* had some of

its feathery branchlets weighted down by a profusion of dark chocolate or blackish-brown berries. As planted out and grown vigorously, this species is very ornamental with its glaucous-green stems and white bracts or spines.

Before leaving the garden with its cool fernery, rock garden, fine trees, and charming views, I was introduced to a charming young lady-gardener of six, who does a good deal of the machine-mowing on the lawns. "Miss Jeannie," the garden donkey, is quite an important personage, and a great pet with the children to whom she looks for a share of their cakes, biscuits, or sweets, in quite a sisterly manner. As I saw her with white Japanese Wind-flowers in her bridle, she looked very coquettish and attractive, and it was no detraction from her good looks to hear from Mr. McKimm that she is quite as useful and willing to do her best as are some of the less attractive members of her family.

I could say much more of the Belfast Botanical Garden-Park, as it is now called, but I could not feel more keenly than I do as to its great and far-reaching importance on the garden taste and artistic training of the young and old—"young men and maidens, old men and children"—of a great and thriving city; and I may add my earnest conviction, viz., that if garden-loving people visit Belfast without seeing its public garden, they will have missed much that it is a pleasure and a privilege to see and admire. *F. W. Burbidge.*

MARKET GARDENING.

HEATING FORCING HOUSES.

WE will now consider the heating of the description of forcing houses described on p. 20. The Melon and Cucumber-houses for early forcing should be provided with three 4-inch hot-water-pipes on either side, two of them being flows, placed one above the other, running alongside and close up to the piers or division walls, and one return close to the pathway; the flows being suspended by hooks made of bar-iron $\frac{1}{4}$ inch by 1 inch, and screwed on to the wall-plates, thereby conferring additional stability to the whole of the structure thus attached to the hot-water pipes. All things considered, I think joints made of cement are the best. These are easily and quickly made. White yarn is cut into lengths sufficient to go round the 4-inch pipe three times when placed in the socket. Two rounds of this are driven with the caulking tools into position round the end of the pipe close down to the socket, the two ends of the remaining round of yarn being brought together at and a little out from the top of the socket, so as to form an aperture. Several joints having been operated on in this manner, fill a half-pound coffee-canister with Portland cement, made to the consistency of thick paint, and empty the contents through the aperture indicated into the joints prepared for its reception, so as to completely fill the vacuum between the second and third round of yarn, tapping each joint with the caulking-iron as the work proceeds to ascertain that no empty space remains in the joint being made. After the cement has partly set, the third round of yarn should be driven home, and the several joints faced with stiff cement, and so on until the pipes are all fixed, including, of course, the necessary connections and valves. If the ground inside the several houses gradually rises from the boiler-end of the house all the better, as the suspension-hooks (which should have half-inch of the top of each bent to the angle of the wall-plate in order to grip the latter), can be made all one length, the pipes following a particular course of bricks a little distance from the floor-line the entire length of each house. A throttle-valve should be put in each of the flow-pipes in every house to regulate the circulation of heat. Diaphragm valves should be fixed in flow and return-pipes of any house or houses that are not likely to require heat during mid-winter, as, for instance, vineries and peacheries, but which will be connected with a heating apparatus that will be in use throughout the year. This will permit of the water being drawn from the pipes to prevent injury from frost. The same number of hot-water-pipes recommended above will be sufficient for warming the larger houses provided for the growing of Grapes and Peaches, and they should also be fixed and suspended by hooks. Thus supported there is no fear of the

pipes shifting in any way, as is sometimes the case when supported by bricks. A three-quarter-inch brass draw-off-tap should be screwed into one of the flow-pipes in each house at the warmest end; putting one in both flow and return-pipes (lowest end) in houses provided with diaphragm-valves for the purpose of emptying the pipes when necessary. When making stokeholes, provision (in the way of a series of 3-inch earthen-pipes) should be made, if possible, to carry away any water that might at any time accumulate. *H. W. Ward, Rayleigh.*

(To be continued.)

AMERICAN NOTES.

SUSPENSION OF "GARDEN AND FOREST."

IT is at once a public calamity and a public disgrace that *Garden and Forest* should have been forced to leave the field. We still have some good gardening papers left, and several journals of a general agricultural character which devote more or less space to horticultural matters; but the suspension of *Garden and Forest* leaves America wholly without any publication which may stand for the real advancement of the knowledge of horticulture without any horticultural journal of sufficient editorial dignity to attract contributions of original research, or of permanent value. The horticulturist who has now a new species of plant which he wishes to publish must send his MSS. to a botanical journal. If he has a well-studied critic of some pomological question, he must file his notes and wait. And *Garden and Forest* had a reputation for real literary excellence which commended it to the tastes of educated people; and it was always felt to be authoritative, so as to be safely relied on by scientist and practical horticulturist alike. But with all this "there are not enough persons interested in the things to which *Garden and Forest* was devoted to make it a paying venture." That is what gives us such a disconcerting view of ourselves. We thought we were getting to be students of horticulture in America. It is hardly likely, however, that the verdict of the publishers will be accepted for long. It is more probable that we shall soon have some sort of a candidate for the vacant place. Meanwhile with our regrets for *Garden and Forest*, we mingle the hope that there will not be too many competitors for its insufficient clientele but that there will be one worthy successor.

JAPANESE PLUMS AGAIN.

There is hardly a subject within the scope of horticulture which elicits such sure and general interest in this country as anything regarding the Japanese Plums. Public attention does not seem to be abated even by the growing certainty that these fruits are not at all likely to supplant the European and native varieties. Professor Bailey of Cornell, who has given these fruits special study since their introduction, has just published his third report, in which he says, he is still convinced that the Japanese Plums have come to stay. The nomenclature of these Plums is wonderfully and terribly mixed, in spite of their recent introduction, and Professor Bailey has spent considerable pains in its simplification. While it will be very difficult to secure anything approaching a unanimous consent to Professor Bailey's somewhat radical treatment of synonyms, still it is very much to be hoped that his publications will be taken as the standard of nomenclature in this group as far as possible, for they represent by far the best study yet given to this subject, and even an imperfect standard is better than none at all. When the various Japanese Plums are introduced in Europe by way of America it would save a repetition of much of our confusion if some definite system of nomenclature could be followed, and Professor Bailey's will naturally receive early attention. *F. A. Waugh.*

FRUIT OF PASSIFLORA EDULIS.

FOR many years I grew this fruit in quantity and I am rather puzzled with the editorial remark at the close of Mr. W. Swan's note, viz., that *P. edulis* is deliciously fragrant, but there is nothing to eat in it. Why, I have sent bushels of *P. edulis* [of gardens. Ed.]

the dessert-table, and few fruits were more readily devoured. They were often served in silver egg-cups, the tops cut off, and the rich orange-coloured pulp taken out of their purple shells with the help of silver spoons. The whole fruit, including the seeds, is pleasant eating, and as the rind is specially thin, there is so much found to eat that few, unless gourmands, care to eat more than two at a time. The flavour is distinct, refreshing, and with a dash of acidity somewhat resembling Oranges, though unlike any other fruit.

As to fragrance, I assume you are comparing the fruits not the flowers, as of course *P. alata*, *quadrangularis*, *macrocarpa*, *amabilis*, and all of that family,

fruit, of which you give such a good illustration in *Gardeners' Chronicle* for December 25. The leaf given as *alata*, however, is far too small for well-developed foliage in a plant-stove of this true *Granadilla*. The leaf seems hardly bigger than that of *Passiflora edulis*. So far as the quality of those big Passion-fruits go, I was never able to find much difference, if any, between the three most popular ones, or one species under several forms or names, viz., *quadrangularis*, *macrocarpa*, and *alata*. Formerly parts of glasshouses, and sometimes entire houses, were devoted to the culture of these basket Passion-flowers, for dinner-table decorations and for the fruit for dessert. The former, if put on at the

with its golden pretty fruit depending in quantity from roofs. *D. T. Fish*, 12, *Fettes Row*, *Edinburgh*. [The fruits of *quadrangularis* and its allies are fleshy, like a Melon; in *edulis* there is something to suck, but little or nothing to eat. *ED.*]

THE WEEK'S WORK.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

Seakale.—Where it is proposed to cover some roots of *Seakale* with pots and litter, instead of lifting and forcing them, it may now be economically done, the

FIG. 20.—CASCADE AND POOL IN THE ROCK-FERNERY, BELFAST BOTANICAL GARDEN, (SEE P. 50.)

are far ahead of *P. edulis* in the fragrance of their magnificent blossoms. But in the matter of the aromatic fragrancy of their pulp, *Passiflora edulis* is again an easy first. In fact, after many years' experience with the true *quadrangularis*, or *Granadilla* of the tropics, I still consider *P. edulis* as the only Passion-fruit we grow in Britain really worth eating; and also that those who know how to eat it will find plenty to eat.

As you justly say, *P. edulis* and *P. quadrangularis* should be, and are very different. Not only do the plants, flowers, fruits vary so widely in form, colour, size, but *edulis* thrives best in a cool greenhouse. *Quadrangularis* needs stove temperature to develop freely its fine blooms, and perfect its huge

at moment, will go through the dinner with more or less wide-open eyes, and steep the room in fragrance, and the fruits will complete the tropical cast of the dinner; while *P. edulis* will generally be eaten raw, or be in urgent demand for ices, jellies, and preserves.

As mere garniture for the dessert table, the common blue Passion fruit (*P. cœrulea*) which ripens of a rich golden or soft yellow colour about the shape and size of a bantam's egg, is highly ornamental, but as insipid as beautiful. *P. edulis* I repeat is (the only) Passion fruit worth eating in our climate. It also deserves its specific name, as it fruits profusely under cool greenhouse treatment without the trouble of special culture or the artificial setting of the blooms. *P. cœrulea* also becomes a new plant for ornament

roots starting into growth more readily now than earlier. The best method is to provide proper *Seakale*-pots, with moveable covers for placing over the crowns, and failing these, large flower-pots may be used, well-prepared fermenting tree-leaves and stable-litter being placed between and above the pots as to produce a temperature of 55° to 60°. To produce the plump and delicate heads that are so much appreciated, the blanching must be thoroughly done, an examination of the growing heads being made occasionally after the lapse of three or four weeks in order to ascertain their condition. When the shoots are 6 inches long, then is the right time to take them, in doing this taking a small portion of the woody part of the root-stock; and covering up snugly as before, if more shoots are coming up. When the whole of the heads on a bed are gathered, remove the litter, and cover

the crowns with just enough of it as will protect them from sudden exposure to cold.

Horse-radish.—For this crop choose a piece of ground in the open away from trees, trench it deeply, placing a heavy dressing of decayed manure in the bottom of the trenches. Select young straight roots from 9 inches to 1 foot long, each having one crown only; plant them 12 inches apart each way. It is a good plan to plant a fresh bed every year in a new piece of land. In this way good handsome roots will be obtained with but little expense in time and labour.

Spring Cabbages.—Owing to the continued mild weather, the autumn-planted Cabbages are in a very forward state, and there is danger of them being injured by late frosts. If weather permits, plant-out some of the young plants remaining in the seed-beds; also examine the autumn plantations, cutting any that are hearted.

Early Cauliflower and Cabbage.—Seed of early varieties of Snowball Cauliflower, and Cabbage may be sown on a gentle hot-bed, or in pans, placed in a warm greenhouse. When the seedlings are up, be sure to afford them air in sufficient quantity, and as much light as possible, as will prevent a spindling growth. If left long in the seed-box, pan, or bed, they are apt to damp-off, therefore prick them off as soon as they are large enough to be easily handled. Let the plants be well hardened before planting them out at the end of March or in April.

Broad Beans.—A sowing of early Mazagan may now be made in deeply-dug soil that has been well manured for some previous crop. Broad Beans transplants with good results, and some seed of this variety or Early Longpod may be sown in boxes and afforded the same kind of treatment as that needed by early Peas.

Miscellaneous.—Proceed rapidly with digging and trenching; keep up the supplies of salading by sowing, or planting, or blanching, as in the case of Endive or Chicory—a little at a time, and often.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Peaches and Nectarines.—The older varieties of the Peach—Royal George, Grosse Mignonne, Noblesse, Bellegarde, and Barrington—and Elruge Nectarine, if started now to be forced, will be ripe in June; whereas the newer ones, as Early Alexander, Waterloo, Amsden June, and Hale's Early, Peaches Early Rivers, Lord Napier, and Nectarines, will be a month before those. The temperature of a Peach-house at the commencement should range from 50° at night, to 55° in the daytime, with fire heat alone, with a rise of ten degrees at the sunshine. In severe frosty weather about 45° at night will be preferable, the use of much artificial heat at night being injurious to the trees, and progress can always be made by day in sunny weather. Let the houses be closed soon after noon, syringing the trees once or twice a day, and damping borders and paths, &c., more or less frequently according as the weather is sunny or the reverse, and affording ventilation by the top sashes or ventilators gradually. At the time of starting examine the soil, and if this be found to be only moderately moist, afford one good application of water, and do not afterwards allow the soil to get into a dry state.

Figs.—Trees, the forcing of which is commenced at this date, have a long season before them, and which is necessary if the best results are to be obtained from them, as it allows of a second crop of fruits maturing. Previously to starting the trees, wash them with an insecticide, to remove scale, and well scrub the woodwork and hot-water pipes, and limewash the walls. If the trees are in a fruitful condition, and the border is filled with their roots, it will suffice to clear off the surface-soil and replace it with turfy loam, mixed with one-sixth part old mortar-rubble, one-twentieth wood-ashes, and one-fiftieth bone-meal. If the soil is approaching dryness, afford a thorough application of tepid water. A suitable degree of warmth at first is 50° at night, 55° by day, with fire-heat alone, but allowing a rise of 10° if the sun should shine. When the wood-buds begin to push visibly, increase these temperatures about 5°. Let the house be ventilated in the morning whenever the outside conditions make it desirable or safe, and close the house at an early period in the afternoon. Syringe the trees at the commencement once only on sunny days, and at other times, if the atmosphere of the house should be dry, let only the floors and the border be damped. Earlier-started trees having begun

to make growth may be kept at 55° to 60° at night, 65° by day with fire-heat, and 75° by sun-heat, allowing a rise after being shut early of 5°. Ventilating must be cautiously done, in order that cold air be not admitted in a draughty fashion, but increasing the amount a little at a time at the top of the house as the temperature rises by sun-heat, bearing in mind to close the house early. In mild weather a trifling amount of ventilation may be given at dusk, to remain through the night, except during snowstorms or in very severe weather. Let the syringing be done early in the afternoon, in order that moisture may dry up before night, and always ply the water on the lower sides of the leaves. Disbud and remove superfluous shoots; and before any of the young shoots reach the glass, let them be tied to the trellis.

Early Fruiting Figs which may be growing in pots plunged in mild bottom-heat, unless this is afforded by hot water, will require fresh material added occasionally, in order to maintain a bottom-heat of about 75°.

Peaches.—The trees for furnishing late fruit should be kept very cool, short of allowing the water in the hot-water pipes to freeze. The pruning, dressning, and securing of the trees to the trellis should be carried out forthwith; and any that show signs of weakness should be top-dressed, after taking away the soil down to the roots. The same kind of soil as that recommended in a previous Calendar for Vine-borders is very suitable, with the addition of a 6-inch potful of bone-meal instead of a 5-inch one.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Annuals Suitable for Bedding.—Of these plants I will mention a few, giving methods of raising and treatment in general. The Tom Thumb varieties of Antirrhinum may be obtained from the seedsman in three distinct colours—white, yellow, and red or crimson, the height of the plants being between 6 inches and a foot; and for forming the edgings to large flower or shrub-beds, or filling smaller ones, these Antirrhinums can scarcely be surpassed. The seed may be sown this month or next in slight heat, and the plants pricked out in boxes at about 4 inches apart when large enough to handle, using a small quantity of half-rotted manure at the bottom of the boxes, into which the roots will penetrate, and keep the soil from falling away from the plant when planting them. The plants can be planted with safety in the early part of May, providing they have previously hardened-off. The best of the white Antirrhinums is Queen of the North, the flowers being large and pure white; the plants grow from 12 inches to 18 inches high, and the flower-spikes stand erect above the foliage; for filling large beds, and as a pure white-flowered variety, it has no equal. *Calendula officinalis*, in its several varieties, is another fine annual for bedding-out, flowering continuously all the season. The finest varieties of this plant are Orange King and Lemon Queen: the names indicate the colours. The flowers are large and well formed, and the plants grow 1 foot high. The same kind of treatment in raising the seedlings is required for this as for the Antirrhinums, excepting that they may be pricked-out into a frame, and planted out a little earlier in the season; they are excellent subjects for planting in dry or poor soil. Annual *Chrysanthemums* are very useful plants for filling large beds. The varieties vary in height from 18 inches to 2 feet, and the colours of some of the species are very pretty. *C. carinatum* has a white-and-yellow band, with a brownish centre; *C. carinatum* Purple Crown is a dwarf-growing variety, growing 8 inches in height, and the flowers are a mixture of purple and scarlet, and that of the foliage a bright yellow. The seed should be sown in February or March, broadcasting it thinly in a frame, or in boxes, and planting out in May. *Dianthus Heddewigi*, the Japan Pink, and *D. chinensis*, the Indian Pink, are plants whose beautiful colours of various shades lend themselves to bedding purposes with good effect. The plants vary in height from 6 inches to 1 foot. If seed be sown in February or March, and the seedlings pricked-out as advised for Antirrhinums, the plants will be ready for the beds in May. This plant succeeds better if treated as an annual than as a half-hardy biennial. *Godetias* have been greatly improved in recent years, and for filling beds in flower-gardens they are very fine. The varieties vary in height from 6 inches to 18 inches. The dwarf variety of *Lady Albemarle*, with its bright crimson flowers, is well adapted for the edging of beds con-

taining white-flowering plants; *Duchess of Alban* is pure white, and is also very useful; *Glorious* has very dark-red flowers; and *Bridesmaid*, white ones, which are striped with rose; all of which are very effective plants. They are of bushy habit and this should be borne in mind in planting them. *Nemesia strumosa*: this, as a bedding annual, was to have had a great future. There are many varieties, but the most effective is a rich orange, and the beauty of a bed of this one is not easily forgotten, possessing, as it does, a colour that is peculiarly its own. The end of January is the time to sow seed of *Nemesias* in heat. The seedlings should be potted off into small 60's, as the plants require a gradual hardening-off before planting them at the bedding-out season. *Phlox Drummondii* is a well-known annual, but not so extensively used as a bedder as the richness and variety of its flowers would warrant. It is rather long in coming into flower, but after it does so, it continues with great profusion the whole of the autumn. The chief secret in managing *Phlox Drummondii* is not to let the plants get any check to growth before planting-out time, for should the growths get woody in the least degree, growth is slow, and the flowers few. *Marigold Legion of Honour*, for ribbon-borders, small beds, and as an edging-plant, has no equal among annuals. It grows 9 inches in height, and has flowers of a bright yellow tint, with a brown blotch on the florets. It is a variety always coming true from seed, and the plants maintain an uniform size. No other annual flowers more freely, or suffers less from drought. Sow the seeds in February or March in mild heat, prick out the seedlings in a cold-frame, or into boxes, and it will be ready for bedding-out at the usual season.

General Work.—Take up and relay turf on uneven lawns and much-worn and reduced verges; re-gravel and turn walks that are much worn or very dirty, and all grass edges and verges. In mild weather box-edgings may be relaid. Keep the brooms in frequent use; and during wet weather get all the necessary quantity of pegs, labels, Dahlia and Holly-hock-stakes prepared. Newly-planted trees and shrubs should be examined, and if they have become loosened by wind make the ground firm about the stem, affording stakes where required. Keep all beds and borders clear of weeds by hand-weeding, and where it is the practice to employ shoots of evergreens in the flower-beds, remove the worst looking, filling the gaps thus made with fresh ones.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Gloxinias.—A few tubers may now be placed in a box or pan, in a mixture of leaf-mould and sand, and placed in a warm house to start.

Caladiums may be similarly treated to the *Gloxinias*, or they may be potted in small pots in a compost consisting of loam two-thirds, leaf-mould one-third, and plenty of sand, plunging the pots in a slight bottom-heat, and afford water sparingly.

Anthurium Scherzerianum.—Plants that have been removed for some weeks from the stove may again be introduced into the stove; they delight in plenty of heat and moisture, and in being syringed three or four times a day if plenty of heat is at command. If a large number are grown they can be flowered in succession.

Small Edging Plants, and Subjects for House Decoration.—If it be desired to increase such plants as *Panicum variegatum* and *Tradescantia zebrina*, and young plants are better as edging than old ones, cuttings may be put thickly in 54's and large 60-pots, using a compost of two-thirds loam and one-third leaf-mould, with sufficient sand as will keep the whole of the soil porous and sweet, and the drainage sound, the plants requiring a good deal of water when in full growth. Let the cuttings be placed in a close, moist heat, and shaded from the sun. *Selaginella denticulata* cuttings, or rooted bits of this plant, should now be inserted in the same sized pots and soil as advised for *Panicum*. If the *Selaginella* be used to cover the pots and bare parts of the stems of plants employed in the dwelling, or as table decoration, shallow pans are well adapted for rooting it in, or a foot wide border of it may be planted at the back of a vinery. It will grow in any moderately warm house, placing the pots in a coal-ash bottom, and shading them from bright sun. When struck, remove the pans, &c., to a cool-house or pit. *Pilea muscosa* and *P. m. nana* may now be propagated by inserting three cuttings round the side of a large 60's pot, using a smaller size pot for *Pilea m. nana*; they soon strike if placed

heat, and should then be removed to the greenhouse.

Marantas.—Those plants which have been afforded a period of rest, and are in need of repotting, should receive immediate attention. If a pit or frame with a good bottom-heat is at command, plunge the plants half or fully, and they will start freely into growth. Strong, robust-growing species and varieties do well in a fibrous loam, one-seventh of manure, and a liberal addition of sharp sand and charcoal. Some varieties do best if a certain proportion of lumpy peat be mixed with the compost. If the plants do not require larger pots, reduce the ball considerably.

The Forcing-house.—Batches of Lilacs, *Deutzia gracilis*, *Azalea mollis*, *Kalmia latifolia*, *Staphylea colchica*, and *Rhododendron hybridum* should be brought from the cold pits into the forcing-house, washing the pots, and resurfacing where needful.

Miscellaneous.—*Petunia* cuttings may now be put in; plants of *Acalypha* which have become leggy may be cut back, and the tops employed as cuttings, inserting these in small pots, and plunging in moderate bottom-heat. *Dieffenbachias* which have lost their bottom leaves may be cut down, and the tops inserted as cuttings, the stems being cut into short lengths, and placed in pans filled with a light compost, or laid in cocoa-nut fibre in a propagating-box, and afforded a close moist heat. Plants of *Libonia floribunda* now coming into flower may be transferred from the stove to a warm greenhouse. *Lachenalia* blooms will require to be secured to neat sticks in good time, and the plants liberally manured in order to ensure good flower-spikes.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Ærides, &c.—The present is a suitable season for the examination of *Ærides* and other purely epiphytal species. These plants are very liable to be infested by scale on the upper and lower surfaces of the leaves, and low down in the growths. If much infested, freeing them of scale requires great care, so as to do it without injuring the leaves. *Ærides Fieldingii*, *A. Larpentæ*, *A. Houlettianum*, *A. suavisimum*, *A. crispum*, *A. expansum* *Leonæ*, *A. affine*, *A. virens*, *A. Lobbii*, *A. odoratum*, *A. Savageanum*, *A. Lawrenceæ*, and *A. Sanderianum*, grow best in the East Indian-house, and these species should be taken first in hand, the increasing light and warmth causing them to start early into growth, at which time no disturbance of the roots may take place. After cleaning the plants of insects, those that are unsightly from loss of leaves, or which have not enough root-space, should be repotted. Those growing in pots that are sufficiently large, if the plants are healthy, will have many roots adhering to the sides of the pot, which are difficult to dislodge without mutilation, and such plants should be laid on their sides, and have all the old material picked out, dead roots removed, and the whole mass washed out with the syringe and tepid water. After doing this, replace the drainage, and fill up amongst the roots with freshly-picked sphagnum moss, squeezing it moderately firm. When it is necessary to repot a plant, it should be removed from the pot with but little disturbance to the roots. Tall specimens when repotted should be secured to strong neat stakes, and thus hindered from swaying about, that might cause loss of leaves. Air roots when long enough should be pegged down to the moss, which they will in time root into. Let repotted plants be stood in a group at the warmer end of the house, and protected from strong sunshine independently of the other occupants. Damp well between the pots twice or thrice daily for the space of a few weeks, but afford no more water at the root than will enable the sphagnum to grow. Flower-spikes appearing on the plants that have been disturbed, or are in a weakly condition, should be pinched out as soon as observed.

Celia bella, *C. macrostachya*, and *C. Baueriana*, now starting into growth, may be repotted should it be required. In repotting, half fill the pots with clean crocks, and employ as the rooting material peat and sphagnum moss in equal proportions, and a moderate quantity of crocks. The plants require a very light place in the East Indian-house, and water to be liberally afforded till the pseudo-bulbs attain their full size.

Dendrobium Dearei, now growing freely here, is often found difficult of cultivation; and after repeated experiments, I have found that it will thrive when suspended near the roof on the north side of the warmest house, where there is plenty of subdued light. Although growth has begun, the plants

will not be heavily watered before new roots emerge from the young growths. The younger leaves being liable to attack from red spider, should be often cleansed with a bit of sponge, and warm soft soap-suds.

Galeandra Devoniana, a plant of which is now in bloom here, is also a troublesome species under cultivation. It thrives treated as advised for *Dendrobium Dearei*.

Thrixpernum Berkeleyi.—A pretty plant when in flower, but care must be taken not to afford much water to the plant, or the flower-spikes now appearing may decay. It succeeds at Burford low down on a stage in a very shady part of the East Indian-house.

Odontoglossum-house.—Plants of *Oncidium superbiens* and *O. undulatum* are now showing their flower spikes; and owing to the rambling habit of these spikes, which often grow to 8 or 10 feet in length, some amount of training is a necessity, and in doing this the tips of the spikes should be kept well up to the roof. The plants need an abundance of water until the flowers open.

THE HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Apricots.—It will be necessary to prune these now, as owing to the mild weather this season, the trees will probably flower earlier than usual. Prune in such a manner that the growths will be kept as close to the wall as possible, and thus be the better protected. Owing to its stiff, short-jointed habit of growth, the Apricot does not form such regularly shaped trees as Peaches, but the branches should be kept as straight as possible. Train in young growths wherever there is room for the trees to extend, and between the older branches, shortening also all the spurs that project 4 inches or more from the wall, and if any spurs have no buds at the base, remove them entirely. Unless very carefully pruned, spurs upon old trees are very apt to get into such condition, and when this is the case, renovation must extend over four or five seasons, by removing a few of the longest spurs each year. Be very careful that no old nails press the branches too closely, as gumming and canker are easily provoked in this tree. Old walls that have become dilapidated through frequent nailing should be repaired, in order to prevent damage by woodlice and earwigs, both of which are especially fond of this fruit, and would harbour in the crevices.

Protecting Material must be in readiness, but do not put it over the trees until the flowers show colour. Glass copings fitted on iron brackets are the best, or deal-boards may be used; either should be so arranged that they may be easily removed when not required. From the front edge of the coping double fish or other netting should be hung to within 1½ foot of the ground, and may be tied to Bean-sticks placed in a sloping direction against the wall at distances of 16 feet apart, with the lower end made firm in the ground. If Frigi-domo or similar material is used, it will be necessary to remove it on fine days, which will be best accomplished by having rings fitted to the blind at top and bottom to work on wires, one to be fixed on the edge of the coping, and another on short posts at the bottom, 1½ foot from the ground, and 4 feet from the wall. The blinds may thus be moved backwards and forwards horizontally, and must be moved to a fresh position each time; branches of Spruce Fir and Yew also make a good protection against frost, if fixed to the wall at intervals, but are not so readily removed as nets, and are apt to exclude air and the bees.

Scions for grafting must be removed from the trees before growth commences. Select firm, well-ripened shoots of moderate strength, attach a label to each variety, and heel them in firmly close to a north wall or a similar moist place, where no sunshine can reach them. If dry weather occurs, give them enough water to keep them fresh.

Labels.—All newly-planted trees should be provided with permanent labels as soon as planted. Metal labels having the names in raised letters may be easily obtained, and should be nailed to the wall about 1 foot from the centre of the tree; or in the case of pyramid and bush trees, may be secured to one of the main branches with copper wire. Metal labels may also be made at home during bad weather, if a set of ¼-inch type be obtained—each letter should be fitted on the end of a punch for impression by means of a hammer; a set of numbers should also be got to record the year of planting. Use sheet-lead ½-inch thick, cut into strips 5 inches by 2 inches, and print the names on these. They can be secured

to trees in the open by bringing the two ends together over a branch that can be easily reached.

THE APIARY.

By EXPERT.

Surplus Combs and Frames.—To work successfully by the "extracting" method, a good supply of surplus combs or frames will be required, and there is no reason why these should not be of the most convenient size for tiering up with, and kept solely for that special purpose. Nor do we see how there can be any great objection to their use for that purpose, even by those who consider the standard frame the most suitable for the brood nest. My point is this:—Judging from the signs of the times, it may be assumed that by far the greater portion of our surplus honey will in the future be got by tiering or "storifying," and we are quite sure that any bee-keeper (who knew what he was about) having his choice between a box of combs 5½ inches deep, or a similar one in which they were 8½ inches deep, would unhesitatingly choose the former for tiering up with. Having used these shallow frames many years for storing surplus honey intended for "slinging," I greatly prefer them to deeper ones. The combs are not so easily fractured in the extractor, they are more quickly sealed over by the bees, and more readily uncapped. I get my frames more solidly filled with honey, and by the judicious use of foundation we get at least 80 per cent. of them worked with comb down to and all along the bottom bar. Other obvious advantages will suggest themselves to the bee-keeper without my specifying them in the detail. If standard frames be purchased in the flat, they are readily reduced to our ideal of a tiering frame by sawing off 3 inches of the side bars before nailing up.

Excluders.—Another point I would emphasise, and that is the imperative need for the use of excluders made of zinc when tiering. Many object to this because it hinders a free passage to and fro on the part of the bees, but after testing hives side by side, with or without zinc, I find the difference in the amount of honey gathered to be infinitesimal. Now if the expenditure of time and labour is to be minimised, we must keep our surplus boxes free from brood—we do not want to be "always anxious" as to whether the queen has got into them or not—and as to queens pushing their way through the zinc, the chances according to my own experience are so much against it, that I never give a thought to such a contingency. At all events I can safely say that not 5 per cent. of ordinary normal queens will deposit brood in surplus boxes if zinc be used.

Extracted Honey.—It is certain that extracted honey in bulk is a more valuable commercial commodity to have left on hand, than that which is stored in the comb; indeed, I may say the latter is almost unsaleable—after it has crystallised or become solid—unless it be melted down and the wax extracted from it. Those who have a quantity of each kind by them, will readily realize the difference. The bee-keeper can keep his extracted honey till prices improve, it may be in good demand before the present year is out, at a much higher figure than it would fetch if sold now, and it will take no harm by keeping, provided it was fully ripe when extracted. One of the advantages of tiering with shallow frames, is their suitability for regulating the amount of storage room as the honey income fluctuates. It is an exceptionally poor season in which one box of fully-sealed combs cannot be secured, and if, after adding a second box under the first, the income suddenly fails, leaving the latter only partly filled, the contents may be extracted or left for the bees' consumption, at the pleasure of the bee-keeper, while the first box is found to be in prime condition. Since it is of importance to economise time and labour in every direction to enable us to produce honey cheaply, I do not advocate the constant or even frequent use of the extractor in the height of the working season. It is hard work and a July temperature, coupled with the excitement inseparable from it, makes it hot work, while the evils resulting from a rough-and-tumble method of doing it may be better imagined than described. Besides, if surplus honey is safe (that is, if it is sealed over) it is far best left in that finest of all places for ripening it, i.e., the top of the hive where it has been gathered. As the season closes these boxes full of ripe honey can be taken indoors, to be extracted *en bloc*, or as required. I used to think that honey would not pay the producer if it was sold for less than 1s. per lb.; and the only way to make it remunerative at present prices is to reduce in every possible direction the labour and cost of securing it.

TUESDAY, JAN. 25 { Azaleas, Roses, Greenhouse Ferns, American plants, &c., at Protheroe & Morris' Rooms.
WEDNESDAY, JAN. 26 { Japanese Lilies, Continental Plants, Tuberoses, Gladioli, &c., at Protheroe & Morris' Rooms.
 Rose and Fruit Trees, Shrubs, &c., at Stevens' Rooms.
THURSDAY, JAN. 27 { Hardy Perennials, Fruit Trees, Azaleas, Hardy Climbing Plants, &c., at Protheroe & Morris' Rooms.
 Border Plants, Shrubs, Roses, Climbers, &c., at Stevens' Rooms.
FRIDAY, JAN. 28 { Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—38.5°.

ACTUAL TEMPERATURES:—

LONDON.—January 19 (6 P.M.): Max., 54°; Min., 49°.

PROVINCES.—January 19 (6 P.M.): Max., 54°; west, south, and east of England; Min., 42°, north-west Scotland.

Weather mild, dull, and foggy.

Two documents recently received show that the Society is in a very flourishing and active condition. The first is the Report of the Council to be presented to the annual meeting on February 8, of which we reprint the substance in another column. To it is attached the balance-sheet, which is satisfactory, and the list of Fellows and affiliated societies. The second document contains the arrangements for the year 1898, comprising the details relating to the meetings, shows, and publications, an account of the garden at Chiswick, and of the trials to be therein conducted during the present year, the regulations for the examinations, and a statement of the privileges now accorded to Fellows in the way of chemical analyses of soils, manure, water, &c. The Council in this new departure have secured the services of Dr. J. A. VOELCKER, 22, Tudor Street, New Bridge Street, E.C., as Consulting Chemist. The rules for the use of the Library are given in detail, and much has been done to improve the collection, and render it more accessible to Fellows and others. The names of the members of the several committees are added, and a statement given of the regulations affecting each committee. Among the new arrangements, we notice the offer of a Silver Cup by Mr. N. N. SHERWOOD, the Master of the Worshipful Company of Gardeners. This Cup, of the value of 10 guineas, is to be awarded to the exhibitor "who shall obtain the highest total number of marks at the meetings in June, July, August, and September 6" for collections illustrating the suitability of annuals and biennials as cut flowers for decorative purposes."

We may here add that the Rev. GEORGE HENSLOW, V.M.H., has been appointed Professor of Botany to the Society, an appointment which, though long delayed, will give great satisfaction to the Fellows. Messrs. NORMAN COOKSON, JAMES DOUGLAS and THOMAS GABRIEL retire from the Council by rotation,

and it is proposed to fill the vacancies so caused by the election, if the Fellows see fit, at the annual meeting of Sir FREDERICK WIGAN, Bart., J. GURNEY FOWLER, and JAMES HUDSON, V.M.H.

Horticultural Training at Kew.

We frequently receive enquiries from correspondents as to the facilities offered to the young men employed at Kew for improvement in practical horticulture. Some are under the impression that the training is more botanical than practical, whilst others appear to think that "influence," or a "premium" are needed to get a young man in there. Many of our readers, of course, know as well as we do that Kew is open to all, and that ability is the only "premium" required. It may, however, serve a useful purpose if particulars are furnished as to the character of gardeners employed, and the nature of the work done by them whilst at Kew.

The garden staff consists of curators, foremen, sub-foremen, and journeymen. Labourers also are employed, chiefly for outdoor work, and are practically permanent. The journeymen gardeners, numbering about fifty, are employed principally under glass. Their term is limited to two years (a year in the case of foreigners). Sub-foremen are promoted young men who show exceptional ability, and they usually remain until they obtain an appointment either in India, the colonies, or at home.

The terms of employment are stated in the following form of application:—

"Applicants for admission as gardeners into the Royal Gardens are furnished with a copy of this paper, which, when filled in, must be signed by their present or last employer, and returned to the Curator, accompanied by a letter in applicant's own handwriting, and with testimonials from employers or practical gardeners.

The wages are 21s. per week, with extra pay for Sunday duty.

Applicants must be at least twenty, and not more than twenty-five years of age, and have been employed not fewer than five years in good private gardens or nurseries. They must be healthy, free from physical defect, and not below average height.

No application will be entertained from men who have not had experience in the cultivation of plants under glass.

The applicant will be informed if his name has been entered for admission, and, on a vacancy occurring, he will, if appointed, receive notice to that effect. Should there be no vacancy within three months from the date of the application, it must be renewed if employment at Kew is still desired. If not renewed, the name will be removed from the list of applicants.

Gardeners whose conduct is satisfactory, will be eligible, as vacancies arise, for the positions of sub-foremen at Kew, and for such employment at home, or abroad, as may be at the disposal of the Director.

Name
 Age
 Employer's signature....."

The duties of these men are the care and cultivation of the collections of plants under the direction of the foremen, each man having a definite charge for which he is responsible. They are moved from one department into another periodically, so that a man who does the full two-years' course usually has a certain amount of experience in every department. During the day his work is practical gardening pure and simple. He is encouraged to take an interest in maintaining the collections in the best possible health, whilst habits of tidiness, finish, order, economy of materials and smartness generally are insisted upon. For about ten hours every day he is therefore employed in

potting, cleaning, training, watering, &c. The men employed in the houses to which the public have access, keep watch on the behaviour of visitors.

Courses of lectures are given by stipendiary lecturers for the benefit of the gardeners in the evening after working hours, in a lecture-room provided by the authorities. The subjects dealt with are Systematic Botany, Economic Botany, Geographical Botany, Chemistry and Physics. Certificates are awarded to men whose note-books show satisfactory study. A Field Botany Club is also formed, and prizes as well as certificates are awarded for collections of dried, mounted and named British plants. A Mutual Improvement Society holds weekly meetings during the winter, essays and discussions upon professional subjects being contributed by the men themselves, one of the officials acting as chairman. Prizes for the best essays are given by Sir JOSEPH HOOKER and others.

A well-stocked library is provided for the use of the gardeners, who have access to it every evening until ten o'clock. It will be seen that the young men at Kew are not "coddled," and that skill in practical horticulture is a *sine qua non* in their training both before and after their arrival at Kew. The Director has said:—"We treat our young men as 'men,' and expect them to work out their own salvation. We wish them to be manly, self-respecting, and strenuous; we put, with the aid of the Government, what help we can in their way, and leave them to make an intelligent use of it."

Five years' ago a Guild or Association of Kew gardeners, past and present, was formed, and it has since published annually a Journal in which there is a list of all the members with their positions and addresses. From this it appears that there are about 500 "Kewites" distributed all over the world. The majority of these are still professional gardeners, but a considerable number fill positions of responsibility either as curators of Botanical Gardens, superintendents, &c., no fewer than fifty-three hold such positions in the Colonies and India, whilst the curators of all the Botanical Gardens in the United Kingdom were trained at Kew. Many are head-gardeners, and some are now nurserymen.

There is here evidence sufficient to show that the system in practice at Kew is on the right lines. Of course, a great deal depends upon the intelligence and zeal of the man; but given these to commence with, the progress made in professional knowledge from a two years' course at Kew is most marked.

It cannot be too often insisted that horticulture is an art which can only be learnt by actual practice, like the making of boots or the building of a ship, and he who has had much practice in good gardens is a better gardener, other things being equal, than he who has had less. Education, both of a scientific and of a general character, has the same effect in a horticultural calling as in any other. The contention of those who take what is termed the practical side, in opposition to the theoretical side, so-called, is simply this—that the man who is taught in the class-room how to cultivate Orchids, or Peaches, or Peas, has a poor chance against the man who has learnt this work in the garden. Such, at any rate, is the lesson that is taught by what one sees at Kew; at the same time, the man whose brains are trained as well as his hands, can learn his lesson the more quickly, and turn it to account when the mere practical man has, in this respect, no advantage over his forefathers.

ROYAL GARDENERS' ORPHAN FUND.—We have the pleasure to announce that CHARLES E. REYSER, Esq., has kindly promised to take the Chair at the Annual Festival Dinner of the Royal Gardeners' Orphan Fund, on Wednesday, the 20th of April next, at the Hôtel Métropole.

KEW PALACE.—A paragraph, sent us by a news agency, of which we made use last week, adding some comments of our own, contained some annoying blunders which escaped our notice at the time. "Princess" CHARLOTTE, of course, was never "Queen" CHARLOTTE. It was the Queen who died at Kew Palace; the Princess died after child-birth, at Claremont.

rendered good service to his native country on important occasions. The army also paid to M. Linden's memory that tribute to which his rank as Commander in the Order of Leopold entitled him. Detachments of various infantry regiments greeted with a volley the body of the departed at the exit from the mortuary chapel and at the entrance to the church; the King sent his private band of Guides, who played funeral marches from the Rue Belliard to the Church of St. Josse-ten-Noode. The scientific, horticultural, literary, and artistic world, and the magistrates were largely represented. A number of the horticultural societies of the country were associated for the occasion. A number of telegrams

botany and horticulture by M. Linden. M. Paul Hymans spoke as the representative of the old students of the Brussels University; and M. Em. Lebrun, in the name of the staff of L'Horticulture Internationale, bore testimony to the respect and admiration in which their late chief was held, and expressed sympathy with the surviving members of the family.

— We omitted to mention that the details of M. Linden's career that we published last week were reprinted from an earlier volume, and were originally derived from an article in the *Illustration Horticole*, by M. Rodigas. In an advance-sheet of the forthcoming number of the *Bulletins d'Arboriculture, &c.*,

FIG 21.—COOL FERNERY IN THE BELFAST BOTANICAL GARDENS. (SEE P. 50.)

FUNERAL OF M. JEAN LINDEN.—The respect shown to the memory of the late JEAN LINDEN on the occasion of his funeral bore testimony to the esteem in which the deceased was held. The KING, on receipt of the news of the death, caused his Maréchal de la Cour to express to the bereaved family his sympathy with their loss. The King was also officially represented at the funeral by one of his Generals. The Government of the Grand Duchy of Luxembourg sent a message of condolence to M. Lucien Linden, and instructed the Comte d'Ansembourg, the Chargé d'Affaires, to represent them at the funeral. Jean Linden had been Consul-General of Luxembourg, and in that capacity, when that district had no minister in Belgium, he

of condolence, wreaths and crosses of natural flowers were sent. The *chapelle ardente* was filled with fine Palms and with flowers, among which stood the bier. Among the Orchids, *Cattleya Trianae* and *Odontoglossum crispum* were conspicuous, being species particularly esteemed by M. Linden. There was also a branch of *Malpighia ilicifolia*, the first plant brought home from his voyages by M. Linden in 1838, and still in existence in the houses of L'Horticulture Internationale. At the grave-side, various orations were pronounced. M. Kegeljan, an old and valued friend, paid an eloquent tribute to the deceased; M. Em. Rodigas, in the name of the Ecole d'Horticulture and the Chambre syndicale des Horticulteurs Belges, spoke of the valuable services rendered to

with which we have been favoured, we find that in a speech delivered by M. Rodigas, on the occasion of the funeral, M. Linden is credited with having introduced no fewer than 230 Palms, and 650 new species of Orchids to our gardens! Two closely printed columns of the *Semaine Horticole* are devoted to a list of the names of the plants discovered or introduced by him. It is probable, however, that this list has been drawn up without opportunity for revision.

RETARDING FLOWERS OF ORCHIDS.—It is well known to gardeners, that the flowering period of the Lily of the Valley may be retarded by keeping the rhizomes in an ice-cellar for several months. In this

way, the lovely May-flower may be had in August and September. It is certainly the wish of many an Orchid-grower to induce his plants which flower in the dead season, to bloom at a later time, when their out-flowers are of higher value. That this is not impossible was shown, says our Berlin correspondent, Dr. DAMMER, at the December meeting of the Berlin Horticultural Society, by Mr. DE COENE at Französisch-Buchholz, near Berlin. *Odontoglossum grande* flowers here under normal conditions at the beginning of October. At this season the flowers are of little value, but they would fetch a much higher price if they could be had at Christmas, the New Year, or in January. With this aim, Mr. DE COENE cultivated his plants. He kept them dry until the beginning of June, and that the state of rest of the plants might be as perfect as possible, he took the plants with their roots out of the pots. In the month of June he allowed the plants to grow, and this they did so well, that the bulbs became quite strong and the flowers were partially open at Christmas. At the meeting on December 30, half a dozen strong plants in full flower were exhibited, whilst a good many other plants in the nursery were still in bud, and will open their flowers during January. If this mode of cultivation proves practicable with other species, and it is no doubt that they will be so, then a good many Orchids will be of higher value than hitherto. It would be interesting to learn whether this cultivation has been already applied to other Orchids.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, January 24, 1898, when a paper will be read by Mr. Mr. A. A. HUDSON (Associate), entitled "Surveyors as Arbitrators." The chair will be taken at 8 o'clock. The adjourned discussion on the paper read by Mr. F. PUNCHARD (Fellow), at the last meeting, entitled, "The Royal Commissioners' Suggested Amendments to the Agricultural Holdings Act, 1883," was resumed and concluded. Notice is given that the Annual Dinner of the Institution will take place at the Holborn Restaurant (King's Hall), on Wednesday, February 9, 1898, at half-past 6 o'clock precisely.

ROOFING FELTS.—Messrs. D. ANDERSON, of Belfast, have submitted to us specimens of their roofing felt, which is well adapted for roofing out-houses or sheds, or for lining slate-roofs or wooden structures. When exposed, the felt requires an occasional coating of tar to keep it in good condition. Their marginal hair fabric for covering exposed pipes will save many a "burst."

NORTH PECKHAM AMATEUR CHRYSANTHEMUM SOCIETY.—The annual dinner of this Society will take place on Thursday, January 27, at the Bridge House Hotel, London Bridge, with W. BEAN, Esq., President of the Society, in the chair. A numerous company is expected to attend the function, especially gentlemen connected with the publishing and printing trades.

A RED-FLOWERED MARÉCHAL NIEL ROSE.—Our Rose-gardens are to be enriched by a red Maréchal Niel, the flower of which, it is said, is very large, well-shaped, full, and in form of bud and flower like the yellow M. Niel. It is likewise very sweet-scented, and blooms abundantly on the one-year-old wood; grows strongly, but less so than its yellow namesake. The colour is carmine-red. It is a seedling from Pierre Notting and M. Niel.

THE ADVERTISER'S "A. B. C."—This useful directory, compiled and published by Mr. T. B. BROWNE, of 163, Queen Victoria Street, London, E.C., consisting of 1051 folio pages of letterpress and illustrations, is almost indispensable in the offices and counting-houses of merchants and tradesmen. The volume commences with an advertisement picture-gallery that includes many of the more striking pictorial advertisements of the day. This is followed by a directory in brief, and indices giving the names of all newspapers, magazines, and reviews published in the United Kingdom and Ireland; and succeeding it are lists of those published in the metropolis, and those of the provinces in extended order, with much information concerning each of

value to the intending advertiser or subscriber. Lastly, we have the colonial press directory, with scales of charges for advertisements appended to the notices of the various newspapers, and specimen front pages in the smallest type, filled with advertisements of most of the more important ones. The imports, or the aggregate trade of the various colonies for either the year 1897, or a series of years, form a part of information afforded.

TRIFACIAL ORANGE.—M. DELCHEVALERIE, in his account of the *Parc Public de l'Ezbekieh, Cairo* (Ghent), p. 11, already noticed in these columns, gives the following particulars regarding the trifacial Orange: "Citrus Bigaradia, has long, pointed, often woolly leaves; the petiole is in some cases winged, in others not so. The flowers are white, but tinged with violet outside. When this tree was raised at Florence it was proposed to graft it, but the stock having grown out beneath the graft, it was noticed that the tree bore two sorts of leaves. It was therefore left to fruit. It was at first supposed that two branches, one of the Citron, the other from the Orange, had been grafted simultaneously, and had become united, but, as has been said, the tree produced shoots beneath the graft. Whatever the reason, the foliage shows this peculiarity, that the branches were inter-mixed. At Paris, at HUWARD'S, there was formerly a specimen sixty years old bearing fruits partly Citron, and partly Orange. At Cairo, in the garden of V. R. de CHOUBEAH, formerly the residence of MEHEMET ALI, was one of these eccentric Orange trees from which we have gathered fruits of a three-fold form and nature, one third of each being Orange, one third Citron, and one third rough-skinned Citron."

BRITISH NURSERYMEN AND ENTERPRISE.—A week or two ago, in referring to the number of foreign seed and plant catalogues received at this office, and printed in English for circulation in Britain, we remarked that so far as we were then aware, few, if any, of our home nurserymen took the trouble to print the catalogues intended for circulation on the Continent in the language the recipients could best understand. We have now received two copies of Messrs. COOPER, TABER & Co.'s seed catalogue, one of which is printed in the German, and the other in the French language. We congratulate the firm, and shall be pleased to receive testimony that other houses are equally alive to the importance of being as up-to-date in their methods as are their competitors.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—This excellent Institution held its annual general meeting (H. J. VEITCH, Esq., in the Chair) at "Simpson's," Strand, London, on January 20. The business was of the usual routine description, consisting of the presentation of the committee's report, and the accounts of the Institution; the election of officers for 1898, and the election by ballot of candidates to become pensioners on the Fund. The various resolutions were passed with unanimity. The report stated that during 1897 eighteen pensioners had died, four of whom left widows, and three of these have been placed on the pension list, at £16 per annum, in succession to their late husbands. The names of two pensioners whose circumstances had changed during the year had been removed from the list. The total number of pensioners was 167. Owing to a legacy left by the late J. W. Thompson, at one time gardener to King George III., for the benefit of a widow or widows, it was resolved to put on the pension list the name of the widow who received the highest number of votes among the unsuccessful candidates. Including this widow there were thirty-five applicants over and above the number elected to the funds, which was fixed at nineteen. In consequence of John Battersby, of Carrington, Notts, aged 73, annual subscriber of £1 1s. for thirty-five years; John Berry, of Prestwich, Manchester, aged 74, annual subscriber of £1 1s. for fifteen years; Daniel Boreham, of Rydes Hill, Guildford, aged 71, annual subscriber of £1 1s. for seventeen years; George Daniells, of Alfreton, Derbyshire, aged 62, annual subscriber of £1 1s. for eighteen years

William Davidson, of Coleford, Gloucester, aged 72, annual subscriber of £1 1s. for thirty-two years; Thomas Ffoulkes, of Newcastle, Staffordshire, aged 70, annual subscriber of £1 1s. for fifteen years; John Mit-chinson, of Truro, aged 76, annual subscriber of £1 1s. for twenty-three years; John Perkins, of Thornham, Suffolk, aged 73, blind, life member for fifteen years, also contributed £50; John Rolfe, of Herne Hill, aged 69, annual subscriber of £1 1s. for thirty-six years; and Silas Warr, of Woolston, North Cadbury, aged 71, annual subscriber of £1 1s. for nineteen years—being in distress, and having in every way complied with the rules and regulations, the Committee recommended that these ten applicants be placed on the Pension List without the trouble or expense of an election, in accordance with Rule III. s. 5. The above ten candidates having been elected unanimously, a ballot took place for the remaining nine. The following are the names of the successful candidates, and the number of votes recorded for each:—

HENRY ELLIS	4249
THOS. BUNDAY	3900
ROBT. BEGBIE	3878
JAS. BAKER	3868
WM. WOOD	3790
DAVID CORNELL	3663
GEO. HEWITT	3651
EDWIN THOMAS	3550
LYDIA ROSE	3534
ELIZABETH McCULLOCH (J. W. Thompson bequest)	3031

The Annual Friendly Supper is being held, under the chairmanship of ARTHUR W. SUTTON, Esq., of Reading, as these pages are in the press.

PUBLICATIONS RECEIVED.—*Bulletin of the Botanical Department, Jamaica*, October to November, 1897, contains, among other articles, papers on Movements of Plants, and Elementary Notes on Jamaica Plants.—*Bulletin of Miscellaneous Information*, Royal Botanic Gardens, Trinidad, January, 1898; devoted to descriptions of the Ferns of the West Indies and Guiana (by G. S. Jenman), and dealing with Genus 1. Hymenophyllum and 2, Trichomanes.—*The Canadian Horticulturist* for December, 1897. This number includes a paper by F. W. BUEB on the Loganberry, a new fruit, of the trials of which satisfactory results are reported. It is said to resemble a red Blackberry, and to have the habit of the Dewberry.—*Journal of the Board of Agriculture*, December, 1897. Among other articles is one on an Orchid-bug, *Phytocoris militaris*, to which *Dendrobium Phalaenopsis* is particularly subject. The insect is imported with the plants, and spraying with quassia and soft-soap have proved more efficacious against it than has tobacco-powder.—J. DAVENPORT & SONS, brewers, Bath Row, Birmingham, *Pocket Diaries*, in cloth and leather binding, handy, durable, and provided with much useful information for every-day use.

THE GROWTH OF APPLE-TREES.

AN outcome of the frequently-recurring agitation on the subject of British fruit is, that method in pruning is claiming more attention, with the result that the old-fashioned rule-of-thumb practice of hard-pruning for fruit is giving way to a more sensible treatment of trees. Those who see clearest are being persuaded that the over-use of the knife has much to answer for in the matter of fruitless and unhealthy trees. Pruning is at its best but an artificial way of attaining certain objects, such as adapting the trees to a limited space, or reducing them to some unnatural form, but it has been indulged in so long, and so commonly, and the knife is such a fascinating instrument, that it has long been a part of the gardeners' creed to prune and prune, as if Dame Nature deserved no consideration.

From the time a scion becomes established on its stock till the tree is worn out, it is frequently pruned with severity, although it may show all the while by the thickets of Willow-like shoots that it is a practice resented by Nature. To curtail the spread of a tree, and to produce a symmetrical form of the crown, much labour must be expended in summer and in winter, and from a productive point of view this labour is worse than lost. I grant that fruit-trees

must occasionally be thinned, and that the reduction of length in a branch here and there may be necessary sometimes, but trees grown as nearly as possible according to Nature from the scion or seed have very little tendency to make redundancy of branches, consequently but little thinning of such trees is ever needed. Given a start of a sufficient number of branches to form the main arms of a tree, the less these are

some of the very best fruit-buds; and, worse than this, the buds lower down the shoots develop thereby into gross fruitless growths, instead of fruit-spurs. One plea for shortening branches must not be overlooked, and that is, that it is necessary for strengthening weak ones; but I hold that if one quarter of the time now spent with the knife in a harmful way were devoted to securing shoots that show abnormal weak-

and in a year or two the growth made annually becomes less and less, and is fruitful. I have devoted some care to the raising of seedling Apples, and am pleased so far with the result, in regard to shapeliness and promise in seedlings now six years of age. These have never been touched with the knife, and yet they bristle with fruit-buds and spurs. I can say with confidence that no more shapely or evenly balanced trees than the majority of these seedlings can be produced under any method of hard pruning. If this is so with seedlings, why not with grafted or budded trees? J. C. Tallack, *Livermere Park Gardens, Bury St. Edmunds.*

LÆLIA AMESIANA, CRAWSHAY'S VARIETY.

THE flower of Mr. Crawshay's variety of *L. Amesiana* (see fig. 22) differs from the original in possessing petals of greater breadth, and sepals that are whiter at the base, and of a brighter purple tint at the tips, as are also the tips of the petals. The side-lobes of the lip are marked with a dark claret-crimson colour like the front-lobe. It was shown by the owner at the meeting of the Royal Horticultural Society on January 11 this year (see report in *Gardeners' Chronicle* for January 16, p. 47).

HOME CORRESPONDENCE.

THE KAKI, LOTI, OR DATE-PLUMS (*DIOSPYROS KAKI* VARS.).—I am very glad to hear that the Kaki has fruited at Kew under glass for five years or so, and I am also very pleased indeed to hear that at Bitton, in "a Gloucestershire garden," Canon Ellacombe has succeeded in fruiting it in the open air. I wish that Canon Ellacombe would tell us what treatment his fruiting specimen has received, how long it has grown at Bitton, and also give us some notion as to the size and flavour of the fruits. There are now in cultivation in South Europe and America, as well as in Japan, a numerous series of varieties large and small, some of the kinds being seedless, while others produce from four to eight seeds, not unlike flat Date-stones; hence, no doubt, the popular name of Date-Plum. The United States Department of Agriculture (*Division of Pomology, Bulletin No. 6*) has recently published a catalogue of fruits recommended for cultivation in the various sections of the United States by the American Pomological Society, and on p. 33 of this catalogue an analytical list is given of eleven varieties of *Diospyros Kaki*, all except the variety *costata*, having Japanese names. So far these varieties are only recommended for the warmest southern states, such as Florida and the Gulf Coast of Alabama, Mississippi, Louisiana, and Texas below 100 feet elevation. In North Carolina, South Carolina, and Georgia, below 1000 feet elevation and in Alabama, Louisiana, and Mississippi, between 100 and 500 feet elevation, and in warm parts of other states such as Texas, S.E. Arkansas, S.E. Missouri, S. Illinois, W. Kentucky, and Tennessee, below 500 feet elevation; of the eleven varieties named only one reaches the highest number of ten points for quality, viz., "Tane Nashi." Varieties called "Okame," "Yedo-ichi," and "Kurokoma," are next highest with five to six points each, and then come *costata*, *Hachlya*, and "Taber 129," each with four to five points; the remaining varieties being "Hiyokume," "Tsuru," "Yemon," and "Zengi," which only scored three to four points each. The colours are given as being black, brown, carmine, dark orange red, and salmon, and in size these sorts vary from 1½ inch to nearly 5 inches in diameter. The common or wild Persimmon (*Diospyros virginica*) has long been one of the wild fruits of the United States edible only after the first frosts, and even then not liked by everyone who eats it; and by the same token there are very diverse opinions as to the edible qualities of the Japanese kinds. Writing from Nice lately, Mr. Woodall says, that there, *Diospyros Kaki* has become a popular fruit in the market, and that it is most effective on the dish, or as piled up in heaps, or in baskets on the stalls. He further adds, that, "when quite soft and transparent it is a delicious fruit, but that it is not given to everyone to be patient enough to wait for that happy moment; hence, foolish people call it rough and astringent, while to those who wait, it is like a huge Apricot, melting and delectable." As to hardness, there is no doubt but that the *Diospyros Kaki* will withstand our hardest winters on

FIG. 22.—LÆLIA AMESIANA, CRAWSHAY'S VARIETY.

shortened the sooner will fruit spurs develop, but accompanied by very few superfluous shoots. Any one may prove for himself what an effect the omission to prune has on production of fruit spurs by leaving the leading young growths intact for two years, as in the second year they become studded with spurs from the base to the tip, but, and this point should be noted, the largest and earliest spurs to mature into blossoming and fruitfulness are found near but not quite up to the tips of these shoots, so that even the so-called moderate shortening of branches cuts away

ness into place, both strength and fruit would come, and that two years before a tree, treated to an annual shortening of two-thirds its growth, would give a fruit. Many varieties of the Apple which are noted for not affording fruit whilst young, do not require half the time they usually take, if they are allowed to grow in size quickly. One thing which may deter some gardeners from allowing the development for which I plead, is the great length of the shoots made the first year after the shortening of shoots has been given up, but this excess of growth is soon moderated,

a wall; but it does not follow that it will ever prove a satisfactory fruit-tree as grown in the open air. Mr. G. F. Wilson, years ago, fruited it in an orchard-house, and as a fruit-tree it will, I believe, only be a success with us as grown under glass for at least part of the season. The fruits are so handsome, however, and as Mr. Woodall says, so "melting and delectable" when perfectly ripened, and they come in, moreover, at such a dull time of our year, that they are doubly welcome, and will I am sure soon recommend themselves wherever fruit-culture under glass is carried on. *F. W. Burbidge*. [We received some lately from Algiers; one caught at the right moment was delicious, the others formed an unsavory rotten mass. *Ed.*]

TREES AT MOTTISFONT ABBEY.—I observed the recent illustrations of noble trees at this fine old place with particular pleasure, having seen the original two or three times, some thirty years ago, when visiting the late Mr. Jones there, in the days when Lady Baskerville was alive. Huge as the great Plane-tree was then, it is certain to have increased in bulk and size of crown during the interval. No doubt the vigour of the tree is very much due to the fact that it has ample space, and that its roots have obtained access to the waters of the river Test, which flows somewhat sluggishly along the edge of the lawn, and near to the tree. With respect to the rooting of the lower branches, I think there are few more interesting trees so affected than is the huge Horse-Chestnut at Ruxley Lodge, Esher—a tree as handsome in culture as it is noble in dimensions. Several giant branches of this tree have become embedded in the mossy lawn, and it is evident they are deeply rooted in the soil. The interesting character thus presented is all the more noticeable in winter, when the tree is bare of leaves. It is, I fear, much too large a tree to get focussed into one picture. No doubt these rootings have been aided by the bark of the branches being abraded by friction with the ground, then, becoming buried, they have readily rooted. I should very much like to hear whether the ancient pollard Oak that thirty years ago stood on the river-bank some half mile above the Abbey at Mottisfont is still existing. It was then one of the patriarch trees of the kingdom, and I think its hollow trunk at 3 feet from the ground was 35 ft. in circumference; and all about the ground there was an exudation of bark-growth like to an eruption of lava. Such patriarchs of the forest merit all protection and preservation. *A. D.*

VIOLAS.—Your correspondent, Mr. William Sydenham, of Tamworth, ought to be an authority upon the subject of Viola cultivation, considering the vast number of plants whose culture he superintends so successfully. I am obliged to him for his observations regarding my recent contribution to the *Gardeners' Chronicle*. Any article upon such a theme must necessarily be incomplete for the number of new Violas (each, of course, infinitely superior to its immediate predecessor!) is such as to be utterly perplexing, if not absolutely distressing, to the most conscientious cultivator of Violas. I am glad to learn that Violas bloom for so long a period at Tamworth; it must indeed be very gratifying to Mr. Sydenham to have them flowering so late as January, and so early as March. I regret that, as I do not possess the special varieties to which he alludes (*Britannia*, &c.), I am not in a position to pronounce any opinion regarding their merits. Yet of this I feel assured, that many of the more venerable varieties which are still universally cultivated and admired, will not soon be superseded. "A thing of beauty is a joy for ever." I have finally to express my gratitude to Mr. Sydenham for his kind invitation to visit his garden, which must, I imagine, be very attractive when his 200,000 Violas are in bloom. *David R. Williamson*.

PRUNING APPLES AND PEARS.—Your correspondent, Mr. Kettle, still misconstrues my remarks on the pruning of maiden, standard, and bushes of Apples and Pears. If Mr. Kettle will be good enough to concentrate practical ideas into such a form as to indicate clearly to readers of the *Gardeners' Chronicle* wherein my practise is at fault regarding the "building up of large fruitful trees in as short a time as possible," and at the same time make clear a better or more practical method of doing this, he will be doing them and myself a great service which we shall all of us appreciate. But the running from one point to another of the subject, firing random shots by the way which fail to hit the mark,

does not commend itself to your readers, or tend to elicit sound information thereon, as I feel sure your correspondent is desirous of doing. Mr. Kettle says, in reference to the pinching of the summer growths resulting from the pruning of "misplaced" shoots back to 2 inches, "the said 2 inches would only have undeveloped buds, which in effect," he says, "are all wood-buds," adding, "whereas if they were left at greater length the buds would be more fully (?) developed, and only one (seldom more) would make wood, the buds behind such being fruit-buds." How does he arrive at this conclusion? Are not the buds on restricted growths more plump, more developed, than those on unrestricted growths? Mr. Kettle would allow the "misplaced" surplus shoots to remain at their full length, i.e., to become crowded, rather than sacrifice the terminal fruit-buds by the 2-inch pruning method." And he goes on to say, "If the 5 to 9-inch system be practised, it will be years before you get a dozen fruits, and many more before you gather a gross;" adding, "I prefer long growths and fruit—long spurs (!) and fruit, rather than trees dwarfed with 5 and 9-inch pruning." The words "5 and 9-inch and 2-inch pruning," appear to have had a magical effect on the mind of your correspondent, seeing that he has mixed them up, and repeats them so frequently irrespectively of the meaning which their application by me clearly conveyed. The remarks of mine on Pruning Apples and Pears, misinterpreted and criticised accordingly by your correspondent, apply solely to maidens, as stated at the time, which I practically recommended to be pruned once, with the result that stocks which were grafted in the spring, say of 1896, each scion being furnished with three wood-buds, and [these having pushed into free growth, were pruned back to from "5 to 9 inches" the winter following, each pruned-back shoot producing from three to five growths this year (1897), thus giving to each tree fifteen shoots from last year's (1896) cut-back maidens. I shall be much obliged to Mr. Kettle if he will kindly state, in these pages, a quicker and better method of establishing large fruitful trees. *H. W. Ward*.

A HALL FOR HORTICULTURE.—This discussion has drifted away to a side issue, owing to a remark of mine which Mr. Dean contested. His last contribution to the controversy shows plainly the helpless bondage of the N. C. S. to the Royal Aquarium Company—a most humiliating condition for a society that calls itself a "National" one. The title should, I think, be altered to the Royal Aquarium Chrysanthemum Society. Mr. Dean says I have no personal knowledge of the profits which the Aquarium Company derive from the N. C. S., and goes on to mention various items of cost to them that the shows occasion; but no figures are given by him whereby one may judge of the aggregate amount. Surely Mr. Dean, as an official of the N. C. S., has examined this matter and could give a more convincing answer than he has done on p. 45. Staging would only need paying for once, and deal-boards are cheap. Labour and assistance at shows figure largely in the balance-sheet of the N. C. S., so it is not all supplied by the Royal Aquarium Company; only a portion of the lighting can be specially called for by the N. C. S. But I need not go through the list. Mr. Dean has probably enumerated everything (but without any figures), and has advocated the cause of the Royal Aquarium more strongly than the N. C. S. But if the Aquarium Company is put to a heavy expense over these shows, the N. C. S. is also, as I find £839 for prizes, and £503 for other expenses, mainly connected with the shows and subscriptions in 1896, making a total of £1347 expended; for this magnificent expenditure (which is a credit to the N. C. S.) it is allowed by the Royal Aquarium Company the sum of £300; the rent of space amounts to £120; tickets sold, £51—a total of £471, which is given back to the N. C. S. If, as Mr. Dean contends, the Aquarium Company derives no profit from this arrangement, I can only add that it certainly ought to do so. Mr. Dean appears to entirely mistake my meaning in the sentence referring to the further encouragement of Chrysanthemum culture, and I assure him I did not make the statement, as he suggests, "without thinking about the matter." It is not always advisable to write all that one thinks, but my contention was this:—"If the N. C. S. had all the profits arising from its shows, it would be able to do far more work than it has done hitherto. I willingly admit that it has done much valuable work in the past, and those members who have assisted so conspicuously and gratuitously deserve the thanks of all—more especially as regards the valuable catalogue. But I would

ask, Does nothing more remain to be done? and would not the Society be able to do much more if it had a good reserve-fund, and reaped all the benefit derived from its shows? Mr. Dean mentions £55 being added to the reserve-fund in 1896; if the profits of the four days' show in November had gone into the funds of the Society, this sum would probably have been hundreds of pounds. The total reserve and balance of the National Chrysanthemum Society at the commencement of 1897 was £115 8s. 10d. I could mention a small Chrysanthemum Society in a country town of about 10,000 inhabitants, which has just completed its fifth year, and has already nearly half as much balance as the National Chrysanthemum Society. *W. H. Divers*.

—I have read the correspondence that has appeared on the subject of a hall for horticulture in the *Gardeners' Chronicle*. I should like to see one erected, but to have such as one we have at Peckham, and to make it pay its way is another matter. I have carefully read the correspondence, and I am of the opinion of Mr. R. Dean—that is, there must be some extra attractions of some kind or another, or the visitors, after having examined the flowers, will not know what to do to beguile the time. None but enthusiasts will linger over the blooms. I can assure you, as an assistant-secretary of the North Peckham Amateur Chrysanthemum Society, and the hon. secretary will bear me out, that at our exhibition, after the public have examined the blooms, they at once adjourn to the concert-room, or go down to the ball-room, which is crowded. These facts will, I think, bear out Mr. R. Dean's statements, that the visitors like variety for their money; and for London the most suitable show place is the Royal Aquarium, Westminster. I feel sure that if we had nothing beyond flowers as an attraction, our endeavours to hold a flower show would have ended in failure. We had more than 4000 visitors in the four days the exhibition lasted, and now we require a larger hall in Camberwell. *William Nichols*.

—Mr. Dean has attempted to prove that the Aquarium Company is put to an enormous expense in connection with the exhibition, &c. of the National Chrysanthemum Society, and he quotes printing, advertising, posting, and "many other ways." These items are to be found in the balance-sheet of last year, where it will be seen that about £700 was swallowed up by expenses, and paid for by the National Chrysanthemum Society, this amount being quite independent of the prizes awarded. Will Mr. Dean kindly inform us why the National Chrysanthemum Society requires such an enormous expenditure, that is far in excess, by comparison, with the sums spent by many of the most important Provincial Societies. In the balance-sheet we have Luncheons £30, Annual Dinner £18 (by whom are the invitations sent out?), banquet £93, stationary £28, stamps, &c. £37, special Jubilee ditto £30, show expenses £51 (are not nearly all show expenses?), clerical assistance £75, ditto 7 commissions (to whom?) £11, sundries £11; allowance for extra labour, gas, firing, &c., Jubilee show £25, and Royal Aquarium charge for tickets and commission on subscriptions £53. Bearing in mind that Mr. Dean has informed us that there are 1,500 free passes issued, and the Royal Aquarium Company finds gas and light, are not these items to the total of £75 rather peculiar? Mr. Dean recommends Mr. Divers to try a show in some place in London, depending upon the gate-money to reimburse the outlay. No sane person would attempt such a scheme; but to some extent, such show should depend upon subscriptions, which in the case of the National Chrysanthemum Society amounted to about £300, to say nothing about the handsome profit made from the affiliated Societies. *A. M. N. C. S.*

EUONYMUS IN THE ISLE OF WIGHT.—I herewith send for your inspection a few sprays of *Euonymus*. During upwards of forty years that I have been here, I think I have never seen the bushes flower and fruit so freely as they have done this present season. The bushes from which the enclosed were taken are growing within a few yards of the sea-shore. *David Smith, Gardener, Isle of Wight College, Ryde, I.O.W., January 17.*

FRUIT-TREE LABELS.—Mr. Ward's remarks upon such labels in the Hardy Fruit Calendar for December 25 lead me to mention that ordinary roofing or guttering lead is very suitable material where they can be nailed or wired on. It should be cut into pieces as long and as deep as is necessary to take the name required, and two small holes should be punched, through which to pass the nails or wire. Iron

letter-punches are necessary, and each punch should have 3 inches of spare iron attached, so that it can be held by the hand while the imprint is being struck in the lead. Each letter is then painted white. Such labels last almost a lifetime. The first cost may be considerable, but I think they are most economical in the end. I enclose a sample label, but I do not suggest the contrivance is a new one, for it has been in use here a number of years. *J. Mayne, Bicton.* [The label enclosed, which bears in unmistakable distinctness the words "Keswick Codlin," is similar to those we have seen in use in many gardens for naming trees against walls, the labels being nailed to the wall. It is an excellent and simple device, and Mr. Mayne does well to call attention to such an imperishable type. It is one which has been in use from time immemorial. Ed.]

STATE OF VEGETATION IN SOUTHERN WALES.—I have recently commenced taking my spring rounds in the counties of Carmarthen and Pembroke, and have been surprised at the very forward state of vegetation, especially in Pembrokeshire. The wild Primroses varying in colour from pure white to dark rose and yellow adorn the hedgerows, giving them quite an April appearance; one could gather basketfuls in a few yards. I have gathered Snowdrops daily since Christmas Day, and carried home last Monday a bouquet of wild flowers consisting of yellow Nipplewort, Wild Strawberry, Herb Robert, and the *Chrysanthemum leucanthemum*. On Tuesday, I picked two blooms of the Tenby Daffodil, just opened from a shady lane in Pembrokeshire, and in the same spot many Daffodils are just ready to burst open. The flower most common, however, just now is the Heliotrope scented *Tussilago fragrans*, and patches of the plant several yards in extent can be seen all about Pembrokeshire, filling the air with fragrance. *J. H. Mason, Carmarthen.*

VIOLETS IN FRAMES DAMPING OFF.—I notice in your "Answers to Correspondents" that you attribute insufficient ventilation as the cause, but it is not necessarily so. Our Violets used to suffer very much from damp, although I never had the frames closed in fine weather, and on a very fine day would have the lights pulled quite off the plants. We are near the sea, lie very low, and have a lake a mile and half long, so that our situation is naturally a damp one, and sometimes, during dull and foggy weather, everything is saturated for two or three days together. I find the best preventive against damp, with careful ventilation, is to have the plants well established in their winter quarters early. If possible, plant them where in spring, but failing this, plant early and carefully with a good ball, and keep the crowns well up. I have always found late and deeply-planted plants suffer most. Last April I planted runners in a frame rather closely, kept them close, moist, and shaded for a few days until growth commenced; then gradually hardened off, planted them in frames for winter early in August, and kept shaded and syringed for a few days. The results will lead me to do it again. During the summer I kept them well watered and syringed occasionally with clear soot-water. *T. Down, Wassand, Seaton, Hull.*

FRUIT JUDGING.—In criticising my notes on the above, "H. W. W." (p. 30) ignores the fact that I especially alluded to the Royal Horticultural Society's great autumn fruit shows, my reason for selecting which was, that the varieties to be exhibited in the single-dish classes at these shows are arbitrarily set down in the schedule, and include both Apples and Pears that should cover the season from the date of the show until the following May or June—the latest varieties, in fact, that are grown being among those selected, and rightly so. If my critic's dictum as to ripeness out of season being a merit is to stand good in such classes, it means nothing short of having a lot of good fruits spoiled; and I should like to know where the line is to be drawn. Possibly "H. W. W." would like to see such Pears as Bergamot d'Esperen, Easter Beurré, Josephine de Malines, Winter Nelis, and the like, shown in a ripe state in September; also that the same thing should follow in the case of late Apples. If so, I certainly disagree with him, and I doubt very much if any gardener who has to supply ripe fruit through the season could be found to agree. All that is wanted is to show fine fruits of the particular variety selected; and if it is one not yet in season, ripeness should be considered no merit. For instance, let us take Josephine de Malines Pear. It is well known that this may be had in a ripe state in November, but then what about the dishes for the dessert in February? In assuming that the fruits shown "of the same variety" are

"equal, or nearly so, in size or shape," "H. W. W." assumes too much; for in the cases which I ventured to criticise it was not so, the fruits selected for prizes being decidedly small. I remember a case in point last year, where the judges were apparently undecided in their action. The 1st prize went to a dish of small and ripe fruit; the 2nd to much larger, equally shapely, but green fruits; and the 3rd again to a dish of ripe fruits. The dish here selected for 2nd prize was absolutely faultless, and nothing but the attractive ripeness of those placed 1st gained them their position. Again, taking exhibits of collections of Apples or Pears, I should like to ask your correspondent which would be of most value to the private gardener, a dozen dishes of Pears which would cover, say, six months' supply, or as many dishes all ripe at the same time? The best collection of fruit is the one which covers the longest season, provided the quality is of the best throughout, and the sooner judges cease to be sensible to the glamour of mere ripeness, the better and less artificial will be the methods of exhibitors. I am sorry that my use of the words "dead ripe" needs explaining to "H. W. W.;" I thought that term was well known to convey the meaning of full ripeness, and not the rottenness he suggests—that, at least, was my meaning, and I must apologise for having led him astray. *Cornubian.*

NURSERY NOTES.

A "NEW YEAR'S SHOW" AT READING.

(Continued from p. 4.)

THE GIANT PRIMULAS.—After all, these are the most handsome strains, and will repay any extra attention they may require. They are later-flowered than the others, and were not in full bloom when we saw them. Messrs. Suttons' Giant White is procurable with plain or with fern-leaved foliage. The plain-leaved one has flowers quite 2½ inches across, and they have a pretty orange centre; the flowers of the fern-leaved variety are less flat, and more fimbriated. Both are excellent Primulas in any respect. Giant Pink is an extra good strain, blooms early, and for a long time continuously, the colour being full and pleasing, and the habit vigorous. One of the latest to flower perfectly is Giant Crimson, rich in colour when at its best, having a dark eye, and borne on stout stems, well above the foliage.

Our attention was also attracted by varieties of Primulas that must be termed—

NOVELTIES,

there [being insufficient seed obtainable from them to catalogue such at present. Some of them are sent out in the "mixture" packets, with others not regarded as fixed, and termed "hybrids," the word being used in this instance to describe varieties only. The darkest coloured double or single flowered Primula at Reading is known in each case as Black Prince. The double variety may only be seen at present with plain leaves of moderate size and very dark purple in colour, but the single flowered appeared with plain and fern-leaved foliage in different batches. The flowers are bright velvety crimson-maroon, and have a purple ring around the disc that appears to cast a halo over the flower. Such dark-flowered Primulas will be certain to become popular very speedily, as they are so distinct, and the tint so rich. A few plants there were of another strain also, with plain leaves, and a flatter, better flower than the preceding, but were just as intensely coloured, and will probably be known by the same name. A novelty exists, too, in the only bluish-flowered variety, possessing light-coloured stems—almost white; it has plain foliage, and with its very pretty lavender-tinted flowers the plant has a decidedly fascinating and delicate appearance.

But we shall only stay to mention two others of the newer ones, and the first is Giant Scarlet, a variety that will be sure to please, as it produces large, beautiful flowers, that vary in tint according to their age and the amount of sunlight, but are always bright. Giant Lavender is the other pretty novelty. We have yet to mention the—

STARRY PRIMULAS,

that made such a beautiful display at Reading;

one need not enquire why such a type is being received with favour. One good-sized span-roofed house was filled with plants just coming into full flower. As decorative-plants they are more effective than any other Primula, and the abundant flowers of star-like form (by which we mean that the petals do not overlap or meet each other) are exceedingly pretty. Some are white, with yellow eye, others are lavender tinted; and, again, there are rose or pink flowers, in which a coppery hue may be detected. They are upright in growth, both flowers and foliage have deep purple stems, and the flowers grow tier after tier until a perfect and graceful pyramid is formed.

Primula obconica was represented by some very healthy looking plants in a frame, but we believe the species has still refused to cross with others, and the variations that exist are from its own seed only, or from cultivation.

In several other houses we hastened to admire the beautiful display made by the—

VARIOUSLY COLOURED CYCLAMENS,

for capital strains of which Messrs. Sutton & Sons have long since acquired a merited reputation. It may be doubted which is best known, White Butterfly or Giant White; but each is equally good. The former has a dwarfer habit, the pure white flowers are more spreading, and the foliage is elegantly marked. Giant White has a handsome, bold appearance, upright in growth, larger leaved, and the flowers, which are 3½ inches across, and of great substance, of pure florists' form, are produced higher above the foliage. Other strains in every respect praiseworthy, include flowers of crimson, purple, salmon, pink, rose, cherry-red, crimson-and-white, &c. The crimson-and-white flowers are extra fine, and clearly and brightly coloured. The most noteworthy "fixed" novelty was Salmon Queen, a strain that attracts attention at once by its lovely and distinct salmon-pink flowers; the foliage, too, is handsomely marbled, and moderate in size. Vulcan is strikingly effective by reason of the extra dark ruby-red colour of its flowers, it being the deepest-coloured one in the collection. A curiously tinted one named Purple Queen is noteworthy as showing a shade of colour similar to one almost peculiar to Sweet Peas. The Cyclamen plants of all strains are but a year or so old, have small foliage, sometimes very prettily marbled, and the flowers are of erect growth that require no supports—at any rate, when cultivated as they are at Reading. The colours also being bright and distinct, the strains would be superior ones for market growers.

We saw other plants at Reading: Herbaceous Calceolarias, and Cinerarias in frames; all of them well grown, stocky plants that are certain to flower well. A visit during the next week or two will be sure to amply repay in interest and knowledge those who may make it, and every plant seen will present a perfect picture of cleanliness, skilful cultivation, and uncommon finish.

SCOTLAND.

OSWALD HOUSE, EDINBURGH.

A VISIT to the gardens of this establishment, the town-house of J. Buchanan, Esq., is always of interest, the houses at all seasons of the year being bright and attractive with flowering plants, while among the Orchids some novelties are sure to be found. Chrysanthemums were almost finished, yet some good blooms were still in evidence at the time of my visit of the best varieties. Mr. G. Wood, the gardener here, was the winner of the 1st prize for the group of Chrysanthemums at the last exhibition at Edinburgh. Leaving the fruit-houses, which were receiving their annual cleaning, we come to the Orchid and flowering-houses, where Primulas obconica and sinensis are in force; the variety Sutton's Star being a favourite one for cutting, on account of its lightness and durability when cut. Zonal Pelargoniums, Heaths, and Hyacinths combine to make quite a gay appearance. In the house containing

these plants are the celebrated specimens of Epidendrum (Nanodes) Meduse, grown so well here, and which are being increased as fast as they will grow. Of other Orchids, to the growth of which four houses of a span-shape are set apart, those in flower comprised *Sophranitis grandiflora*, *Masdevallia tovarensis*, *C. Massangeana* in large baskets, with very strong spikes; *Laelia anceps rubra*, a good dark variety. In one house some good examples of *Angraecum sesquipedale* are grown, in a temperature which Mr. Wood informs me sometimes falls to 50° during the winter, and is seldom above 60°. In this house a specimen of *D. speciosum Hilli* was pushing up a large number of spikes; *Brassia maculata*, and a batch of *Aërides* and *Vandas* in excellent health. Some pretty plants of *D. Cassiope* bore a large crop of flowers, forming one of the most useful of winter-flowering Orchids.

Stove plants look in a vigorous condition, and the foliage generally well coloured. Some good plants of *Eucharis amazonica* are among the most showy; *Crotons* in numerous varieties are grown in quantity, while *Palms* of large and small size are in favour here; *Ferns*, including *Davallias*, 4 and 5 feet in diameter; *Dracenas* and other plants necessary where indoor decoration is carried out, were noted; and throughout an air of cleanliness and good arrangement is observable. H.

LADY BELHAVEN'S RESIDENTIAL SEAT IN LANARKSHIRE.

Some of the finest pieces of tree-clad demesnes are situated in and around Hamilton, and have been vastly improved since Sir John Watson, Bart., acquired his extensive holding. Tree and shrub-planting has been the order of the day. Remodelling the foreground has taken place with great judgment, and the emerald lawns form a fine foil for the designs of arboreal subjects dotted down, and for the wavy furniture of evergreen and deciduous tree and shrub life. The principal trees are Oak, Beech, and Sycamore, which will girth 3 feet from the ground over 3 feet, and all show a vigour that is telling among the subsidiary and lesser subjects of evergreen-tree life. The ground-work is covered with the finest named *Rhododendrons*, and they are going along with a vigour that is pleasing to the eye, and are studded with flowering buds that give promise of a wealth of bloom in the return of the flowering season. These, along with *Azaleas*, and many other now leafless shrubs, will cover with floral beauty, and give a charming tone to the various shades of greenery which spring revives. The fine drives which have been put down are lined with grand groups and specimens of variegated *Hollies*, and the whole dress-grounds fronting the mansion are so furnished as to please the critical eye of the best landscape gardener.

The kitchen garden reminds one of the one at Wishaw House, the original property of Belhaven and Stenton. A new range of glass-houses is in course of erection, covering 400 feet; the chief lean-to houses are to be planted with *Peaches*, *Nectarines*, and *Vines*; and the span-roofed houses are to be filled with plants for furnishing flowers for general decoration. There are various specimens introduced, and the houses are all commodious, such as will provide both an abundant supply of fruit and flowers for the needs of the family.

The new trees introduced are largely of the coniferous tribe. I was glad to see the *Douglas Fir* in fine order, and covering considerable breadths, as also the *Crimean Silver Fir* (*Abies Nordmanniana*), as also *Abies nobilis*, which is growing freely among other associates. Altogether it is a charming spot, and will prove a welcome auxiliary to Sir John Watson's estate of Earnock, which lies into and round about it.

EARNOCK HALL, HAMILTON.

This estate was acquired by Sir John Watson, who has turned it to the greatest advantage. 1. By opening up the mineral wealth, putting down such shafts, and lighting-up passages and areas so as to enable the workmen to work the mineral out with ease and economy. In this way the great industry of Lanarkshire, Ayrshire, Dumbartonshire, and other con-

tiguous counties have been fed, and the needs of the people supplied at reasonable prices. The pits in operation have increased, and the turn-out keeps the railways very busy for 100 miles round. His success in this way won him the title of Sir John Watson, Bart., of Earnock, which was a very popular title in this neighbourhood.

Earnock House has been added to, considerable wings have been constructed and finished in the most approved style, and the house is fit for any nobleman or country gentleman that aspires to take the lead in the locality where he fixes his abode. The residential portion is situated on the banks of the river Cadzow, and is a land for the poets to discourse upon; the scenery is more than delightful, and flocks of the people take advantage of the free access to the charmed spaces. Its owner is a poet of the people. He has retained the idiom of the Scotch dialect, and it is a treat to hear him toss off some of Robbie Burns' famed pieces, such as "The Snadrop," "The Cottar's Saturday Night," and other pieces which tell best in Burns' Scots' pure rendering. He has reached the borders of the eighth decade, and long may he be spared to preside at his hospitable table and gather round him a lot of experts, such as he had at the dinner-table on December 11. J. A.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JANUARY 11.—Present: Mr. Michael (in the chair); Dr. Müller, Dr. Russell, Rev. W. Wilks, and the Rev. Prof. Henslow (Hon. Sec.).

Fungus on Beech.—A box of fungi was received from Lady Cave, Cleve Hall, Downend, near Bristol. They were forwarded to Kew, whence it was reported that they were *Pleurotus ostreatus*, Jacq., "one of the best and safest of edible fungi." The specimens were taken from a very old Beech in the gardens of Cleve Hall. They were growing on the wood about 12 feet from the ground.

Report of the Council for the Year 1897-98.

THE year 1897 will long be remembered as the Diamond Jubilee year of Her Most Gracious Majesty, Patron of our Society—remembered, too, for the innumerable projects set on foot in celebration of the event.

In the Report for 1896 the Council announced that they had no intention of adding to the number of projects by starting any ambitious horticultural celebration, which would lay any strain upon the resources of individual Fellows. They stated that they proposed to establish a Medal of Honour in Horticulture, and that they had obtained the sanction of Her Majesty to call it the Victoria Medal.

This proposal has been duly carried out; the Medal has been prepared, and conferred on sixty recipients distinguished in various ways in our Art and Science; and it is believed to be the only Medal associated with Her Majesty's Diamond Jubilee, with the exception of the one founded by herself. It is, moreover, the only horticultural distinction in this country that is conferred for personal merit only, and is entirely unconnected with prize-winning.

By their action in this matter the Council consider that they have commemorated Her Gracious Majesty's Jubilee in a becoming and enduring manner; in a manner absolutely distinct from all other celebrations; in a manner that lays no tax upon the Fellows of the Society; in a manner distinctly to the advantage and encouragement of horticultural skill and effort; and lastly, in a manner which will carry down to all future generations of horticulturists the memory of Queen Victoria's long and happy reign.

Under the head of ordinary expenditure at Chiswick, £1850 has been spent on the general work and maintenance of the gardens. Amongst other work, House No. 11 has been partially, and No. 10 entirely, rebuilt; whilst No. 5, devoted to *Peaches*, has been raised in height, and a new roof put on. All this work has been done by the Society's own staff of men. The receipts by sale of surplus produce amount to £357, making the net ordinary cost of the gardens £1493.

At Westminster, twenty fruit and floral meetings have been held in the Drill Hall, James Street, Victoria Street, and fifteen committee meetings have been held at Chiswick, besides the larger shows in the Temple Gardens on May 26, 27, and 28; and at the Crystal Palace on September 30, October 1 and 2. Lectures have been delivered at seventeen of the meetings, exclusive of those given at the Crystal Palace. The number of Awards granted by the Council, on the recommendation of the various committees, has been as

follows:—At provincial shows, 36; affiliated societies, 30; Fruit Committee, 119; Floral Committee, 502; Orchid Committee, 251; Nardissus Committee, 20; total, 1008.

The Council must again express their opinion that there still appears to be a tendency to multiply unduly the awards recommended, and they earnestly request the several committees to consider seriously whether there is not a real danger of impairing the value of these distinctions by such increase of their number; and whether it would not be possible, as well as politic, to be somewhat less generous in the recommendation of awards during the ensuing year. This is a question which the Council cannot but regard with solicitude, and they hope that every member of the committees will consider that he has a real individual responsibility for the welfare of the Society in this matter.

On Wednesday, July 14, the Council invited all the members of the several committees to lunch with them at Chiswick, and to examine the gardens. After the luncheon an address was delivered by Dr. Maxwell Masters, F.R.S., on the possibilities of an extended usefulness of the gardens. A full account of the proceedings will be found in the *Journal*, vol. xxi., p. 160.

The Council desire to draw the attention of all Fellows of the Society to the more extended use which the Scientific Committee might be to them if they availed themselves more freely of their privileges in submitting instances of diseases of, or injuries to plants, caused by insects or otherwise. The Scientific Committee is composed of gentlemen qualified to give the best advice on all such subjects, either in respect to the prevention or cure of disease. The committee is also glad to receive specimens of any subjects of horticultural or botanical interest.

The Council wish to express their thanks to the Director of the Royal Gardens, Kew, for allowing them to consult Mr. Massee, F.L.S., on the fungoid diseases, &c., brought before the Scientific Committee, and to that gentleman for his readiness in giving them the advantage of his knowledge and advice.

That Fellows, whether near or at a distance, may derive as much benefit as possible from their connection with the Society, the Council have recently appointed Dr. J. Augustus Voelcker, M.A., Consulting Chemist to the Society, and have entered into an arrangement with him whereby all Fellows who are amateurs or *bond fide* gardeners, may obtain, at a very small cost, analyses of manures, soils, &c., or advice as to what description of chemical manure will be most suitable and profitable for application to any particular soil. The Council wish to draw particular attention to two points, viz.:—

(i.) That Fellows desiring an analysis must follow explicitly and exactly the directions laid down in the book of arrangements, 1898, and

(ii.) That Fellows who are in any way commercially interested in any artificial manure trade or horticultural business cannot claim Dr. Voelcker's assistance as Fellows, but if they wish to consult him must do so in the ordinary way of business.

The Society's Great Show, held (by the continued kindness of the Treasurer and Benchers) in the Inner Temple Gardens, was as successful as ever, and it is a matter of satisfaction to the Council to find that this meeting is now universally acknowledged to be the leading horticultural exhibition of this country. The best thanks of the Society are due to all who kindly brought their plants for exhibition, or otherwise contributed to the success of this show.

The exhibition of British-grown fruit held by the Society at the Crystal Palace on September 30, October 1 and 2, was, considering the season, eminently satisfactory.

A certain amount of dissatisfaction has arisen from the fact that whereas classes have been provided specially for amateurs and gentlemen's gardeners, and also for nurserymen, there have been no classes in which growers for market could properly exhibit. This will in future be avoided by the addition of a division for growers for market only.

As an object-lesson in British fruit cultivation, this annual show stands unrivalled, and is of national importance. The Council invite Fellows and their friends to support it, for it cannot be too widely known that the continuance of the show is absolutely dependent on at least £100 being raised by subscription each year towards the prize fund. The show involves the Society in a very large expenditure without the possibility of any return. The Council have, therefore, established the rule that they will not continue it unless sufficient interest in it is taken by Fellows and their friends to raise £100 towards the prize fund. Subscriptions for this purpose should be sent at once to the Secretary, 117, Victoria Street, Westminster; and if the list prove satisfactory, the schedule will be issued in April, and the show held on September 29, 30, and October 1, 1898.

A deputation was sent by the Council, at the invitation of the local authorities, to attend the great horticultural gathering at Shrewsbury in August. The Council gladly embrace this opportunity of congratulating Shrewsbury on the magnificent display of horticultural skill and enterprise made at their show, and of recording the very great pleasure which this visit gave them, and their appreciation of the great courtesy and hospitality with which they were received.

An invitation has been received and accepted for a similar deputation to visit a show, to be held at Newcastle-on-Tyne on July 13, 14, and 15, 1898, by the Botanical and Horticultural Society of Northumberland, Durham, and Newcastle-on-Tyne.

The *Journal* of the Society has been continued, so as to

ble Fellows at a distance to enter more fully into, and the benefits of the study and work of those actively engaged at head-quarters.

An examination in the principles and practice of horticulture was held on April 6, concurrently in different parts of the United Kingdom, a centre being established wherever a magistrate, clergyman, schoolmaster, or other responsible person accustomed to examinations would consent to superintend one on the Society's behalf, and in accordance with the rules laid down for its conduct. No limit as to the position, or previous training of the candidates was imposed, and the examination was open to both sexes. One hundred and eighty-one candidates presented themselves for examination.

It is proposed to hold a similar examination in 1898, on Tuesday, April 5. Candidates wishing to sit for the examination should make application during February to the Secretary, R.H.S. Office, 117, Victoria Street, Westminster.

The Council have heard with much pleasure that G. W. Harrows, Esq., a Member of the Court of the Worshipful Company of Gardeners, has most kindly offered, in connection with the Society's 1898 examination, a scholarship of £5 a year for two years; full particulars of which will be found in the Society's arrangements for 1898, lately issued to the Fellows. Another similar scholarship has been promised for 1899, by the Right. Hon. the Lord Amherst of Hackney, through the same Worshipful Company.

Acting in conjunction with the Lindley Trustees, the Council have devoted considerable attention to the Library. Serial publications have been kept up to date, a large number of valuable volumes have been bound.

The hearty thanks of the Society are due to all the members of the Standing Committees—viz., the Scientific, the Fruit and Vegetable, the Floral, the Orchid, and the Narcissus Committees, for the kind and patient attention which they have severally given to their departments.

A special and very hearty record of thanks is also due to N. Sherwood, Esq., and to C. J. Grahame, Esq. The former gentleman has intimated to the Council his intention of placing a 10-guinea Silver Cup at their disposal annually, and the latter has enabled the Council to very largely increase the prizes offered for Roses on June 28.

The best thanks of the Society are also due to all those who, either at home or abroad, have so kindly presented books to the Library, or plants or seeds to the gardens.

The Council wish to express, in their own name and in that of the Fellows of the Society, their great indebtedness to all who have so kindly contributed, either by the exhibition of plants, fruits, flowers, or vegetables, or by the reading of papers, to the success of the fortnightly meetings in the Drill Hall. They are glad to find by the increased and increasing number of visitors that the Society's fortnightly meetings are becoming better appreciated by the Fellows and public in general. In their judgment, these shows, which take place at short intervals throughout the year, furnish horticultural displays and teach horticultural lessons which cannot be obtained elsewhere in the kingdom.

The Council are glad to be able to announce that they have appointed the Rev. George Henslow, M.A., V.M.H., F.L.S., &c., to be Professor of Botany to the Society, and Professor Henslow has kindly undertaken to give addresses at a number of the 1898 meetings, drawing attention to interesting points connected with some of the plants, &c., exhibited. The Council are confident that these "demonstrations" will be greatly appreciated by the Fellows.

The Council have the sad duty of recording the death of fifty-three Fellows during the year, and among them they regret to find the names of Dr. Robert Hogg, one of the most staunch and energetic supporters of the Society, and the leading authority in fruit nomenclature; James Bateman, the pioneer of Orchid culture in this country, and author of the *Orchidaceae of Mexico and Guatemala*; Col. Trevor-Clarke, William Head, Robert Owen, and James Cocker, &c.

The numerical increase of Fellows after deductions is 325.

A scheme for the affiliation of local horticultural societies was put forward in 1890, and ninety-one local societies have availed themselves of it. The Council express the hope that the Fellows will promote the affiliation of local horticultural and cottage garden societies in their own immediate neighbourhood.

At the request of some of the Fellows, the Council have arranged to send a reminder of every show (in the week preceding it) to any Fellow who will send to the R. H. S. Office, 117, Victoria Street, Westminster, 22 halfpenny postcards, fully addressed to himself, or to whomsoever he wishes the reminder sent.

The Council recommend that the salaries of the principal officers of the Society—the Secretary, the Cashier, the Superintendent, and the Assistant-Superintendent, should continue as heretofore.

The balance-sheet shows a credit balance of £322 7s. 4d. The expenditure on Chiswick was £1851 6s. 1d.

SWANSEA HORTICULTURAL.

JANUARY 7.—The second annual dinner of the above Society was held in the Shaftesbury Hall, Swansea, on the above date. The president of the society, Sir JOHN LLEWELYN, M.P., in the chair; the Mayor of Swansea sitting on his right. The company present, numbering between seventy and eighty, included most of the leading gardeners in the district. The president in proposing the toast of the evening—"Prosperity to horticulture and the Swansea Association," said

he could not do himself justice without congratulating the society upon having such an able and energetic Hon. Sec. as Mr. A. K. Drummond. He, Sir John, was most anxious that the Society should go on and prosper, and be the means of doing a great deal of good in Swansea and the surrounding district, for he felt sure that they had in the society the nucleus of a very important movement.

CARDIFF GARDENERS'.

JANUARY 11.—A meeting of the above Society was held on January 11, when the President, ALFRED THOMAS, M.P., occupied the chair, and an interesting lecture was given by Mr. F. W. E. Shrivell, F.L.S., to an audience of upwards of fifty members. His discourse was based on the results of four years' experiments in the culture of vegetables, with and without chemical manures. The lecturer gave the quantities used for different kinds of vegetables, and exhibited illustrations showing good results from the chemicals. Mr. Shrivell stated that he had no connection with any manure agency.

ANCIENT SOCIETY OF YORK FLORISTS.

JANUARY 11.—The members of this society held their annual meeting in the Agricultural Club Chambers, Pavement, York, on the above date. Mr. Councillor J. E. Wilkinson presided, and there was a good attendance.

The Secretary (Mr. J. Lazenby) read the yearly report, which stated that during the past twelve months the work of the society had been satisfactory. Financially, it was satisfactory to note that at the close of the year's working there was a balance in hand of £180 11s. 11d. as against £177 17s. 1d. twelve months ago. On the motion of Mr. F. W. Halliwell, seconded by Mr. J. C. Milburn, the Report, and also the balance-sheet, which was taken as read, were unanimously adopted.

SOCIÉTÉ FRANÇAISE D'HORTICULTURE DE LONDRES.

JANUARY 15.—On Saturday evening last the ninth annual dinner of this Society was held at the Imperial Restaurant, Strand. Mr. HERBERT CUTBUSH occupied the chair, being supported by a goodly number of gentlemen representing English horticulture, among whom we noticed Mr. J. Weathers, Mr. W. Cutbush, Mr. Harry Laing, Mr. H. J. Jones, Mr. Harman Payne, &c.

The dinner being over, Mr. Geo. Schneider formally introduced the chairman to the assembled company, remarking that the position he occupied in the horticultural world and the interest he took in the work of the Society eminently qualified him for the post of honour which he had kindly consented to fill. In reply, the Chairman complimented the Society on its continued prosperity, which was due in a large measure to the admirable manner in which it was managed by its president, Mr. Schneider, and the other officers. Founded in 1838, the Society has gradually increased in numbers and in its financial resources. Its members are now distributed all over Europe, and there are some occupying important positions in America, Algeria, the Congo, and other distant places, and from these valuable information can often be obtained when occasion arises. He was pleased to find that the balance in hand was much larger than at the beginning of last year, and the library which forms one of the principal features of the Society had received many additions. He therefore proposed the continued success and prosperity of the society, coupling with the toast the name of Mr. Schneider.

That gentleman replied in suitable terms, thanking the members for the excellent spirit of comradeship that existed amongst the members, and the good feeling of their English friends who were always ready to find places for those young foreigners desiring to perfect their knowledge of English and horticulture by a residence in this country, and concluded by proposing the toast of the visitors. Mr. Harman Payne replied. At this juncture Mr. Gachlin made a presentation on behalf of the new members to Mr. Schneider for his kind services to them during the past year, which was duly acknowledged.

The toast of the officers was responded to by Mr. Friedrich. Music both vocal and instrumental filled up the remainder of the evening; "God Save the Queen," and the "Marseillaise" bringing the meeting to a close. A vote of thanks was accorded to Messrs. Cutbush, of Highgate, for the floral decorations.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JANUARY 13.—The January meeting of the above Society was held in the Coal Exchange, Manchester, on the above date. Members of the committee present were Messrs. W. Thompson (chairman), G. S. Ball (vice-chairman), S. Gratrix, A. Warburton, J. Leemann, J. Backhouse, E. Sidebotham, H. Bolton, W. Stevens, R. Johnson, W. A. Gent (Hon. Sec.), H. Greenwood, G. W. Law Schofield, J. Cypher, P. Weathers.

Each meeting of the Society brings forth quite a wealth of plants of great beauty and rarity.

On this occasion Mr. G. S. BALL (gr., Mr. Hay), displayed a superb lot of choice Cypripediums, the best of which was undoubtedly C. × triumphans, a handsome hybrid, showing a dorsal sepal of unrivalled colouring, and remarkable size (First-class Certificate). A good form of C. bellatulum album, with large snowy-white flowers, was also awarded a First-

class Certificate. C. venustum Measuresianum, a lovely little gem—too rarely seen—and which may be described as the albino of C. venustum received an Award of Merit. A well-grown plant of C. Leeanum giganteum, with four flowers expanded, received an Award of Merit. C. Swinburnei magnificum is a plant well worthy of its name, and when seen in such a good form as that shown by Mr. Ball, it cannot fail to find admirers (Award of Merit). C. nitens magnificum also proved to be of the very finest type, and it is doubtful whether such a superb form as that shown exists elsewhere. The committee were certainly too careful in only voting this plant an Award of Merit. Dendrobium Johnsoniæ, or Macfarlanei, from the same exhibitor, showed a spike of nine well-developed flowers, which speaks well for the successful cultivation of this not too easy species (Award of Merit).

Mr. JOHN LEEMANN (gr., Mr. Edge), exhibited a specimen plant of Lycaste Skinneri alba, from which, however, some of the flowers had been removed. Six good bold flowers were displayed. Odontoglossum crispum var., a good form of the Pachy type, received an Award of Merit.

Mr. A. WARBURTON (gr., Mr. Lofthouse), exhibited C. insigne Sandersæ, which showed a slight variation in the tiny spots peculiar to this variety on the dorsal sepal (Award of Merit); also C. × Mrs. Geo. Truffaut, a peculiar production, having for its parents C. Stonei × C. Morganii. It therefore has traces of C. Stonei in it twice, and resembles C. Morganii in shape and markings, except that it has more "nigger" blood in it.

Mr. W. THOMPSON (gr., Mr. Stevens) staged a few good plants, among which were Odontoglossum, odoratum var., deltoglossum Stevensii (Rolfe), a charming variety with a ground colour of creamy white, and bordered for about an eighth of an inch in depth with a sulphur-yellow, the sepals being spotted with chocolate (Award of Merit). C. × Calypso, Winn's var., came from the same owner, and is remarkable for the profuse claret-colouring in the dorsal sepals, making it a very striking variety (Award of Merit). Cypripedium Sallieri also gained an Award of Merit.

Mr. THOMAS STATTER (gr., Mr. Johnson) exhibited a good form of Cypripedium × Niobe, with a good bold dorsal petal well-marked (Award of Merit).

Mr. S. GRATRIX (gr., Mr. McLeod) exhibited a fine hybrid Cypripedium, named "F. S. Roberts," the parentage not recorded, but evidently C. niveum had been used in its production. The colour of the flower was white and densely covered with tiny purplish markings (A First-class Certificate was awarded). From the same collection came a plant of Lycaste Skinneri alba, showing evidence of good culture, and bearing fine flowers. As in Mr. Leemann's case, no award was made.

Mr. O. O. WRIGLEY exhibited C. insigne var. exquisitum, for which he obtained an Award of Merit; the marking of the dorsal sepal was distinct, the spots being peculiarly placed, and, what is seldom seen, violet markings were apparent around the white margin of the dorsal sepal. C. Argus from the same collection received an Award of Merit.

Mr. D. LORD received an Award of Merit for C. Lathamianum giganteum, but which was not particularly gigantic. Mr. H. GREENWOOD exhibited Dendrobium × "Harold" (Findlay-anum × Linawianum), only one flowering being open on the plant; it is a pretty hybrid, and when seen in a more advanced stage should be very attractive. Mr. FRANK HARDY exhibited the C. insigne Sandersæ about which there has been such a great deal said. It is a fine form, and quite equal to anything else bearing the same name. Mr. JOHN ROBSON obtained an Award of Merit for the reverse cross of C. × Pollettianum, which does not differ greatly from the original; and a Cultural Certificate for a large well-flowered piece of C. Boxalli. P. W.

SHIRLEY AND SURROUNDING DISTRICTS GARDENERS' AND AMATEURS' MUTUAL IMPROVEMENT ASSOCIATION.

JANUARY 15.—A meeting of the above society was held at the Parish Room, Shirley, Southampton, on the above date. The president, W. F. G. Spranger, presiding over a fair attendance of members.

The Lecture "Fungi, their mode of life and reproduction," was given by Mr. E. T. Mellor, B.Sc. London, Lecturer in Biology at the Hartley College. A large number of lantern slides were used to illustrate the subject, and added much to the value of the lecture. The method of reproduction was very fully illustrated, and the immense numbers each plant was capable of producing shows how necessary it is to know how to deal with them to stop their ravages.

A hearty vote of thanks to the lecturer and to the president closed the business of the meeting. The subject of Fungi will be continued next meeting, and "Injurious and Beneficial Fungi" is the title of the lecture.

ISLE OF WIGHT CHRYSANTHEMUM.

JANUARY 15.—The annual meeting of this Society was held at Newport on the above date, Dr. GROVES in the chair. The report and balance-sheet were adopted on the motion of the chairman. The balance in hand is over £18, which is about £4 less than last year. Previous to the election of officers a long discussion took place on the desirability of forming an Isle of Wight Championship Prize, which was afterwards entrusted to a sub-committee to discuss and report to the Society. Sir Charles Sooly was re-elected President, Dr. Groves, B.A., J.P., chairman, and Mr. C. H. Cave, Hon. Secretary.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending January 15, is furnished from the Meteorological Office:—

"The weather during this period differed considerably in the various parts of the kingdom. In all the eastern and southern districts it was very dry, but gloomy, and frequently foggy or misty; in most of the western districts it was very fair generally, although slight falls of rain were occasionally experienced; in the extreme north-west it was rainy and unsettled.

"The temperature was above the mean, the excess ranging from 1° in the Channel Islands, to 3° over eastern, central, southern, and south-western England, and to as much as 6° in 'Ireland, N.,' and over Scotland. The highest of the maxima occurred during the middle of the week, and ranged from 56° in 'Scotland, E.,' to 50° in 'England, E.' The lowest of the minima were registered, as a whole, during the earlier half of the period, and ranged from 25° in 'England, S.W.,' and 27° in 'England, E.,' to 32° in 'Scotland, N. and W.,' and the 'Channel Islands.'

"The rainfall just equalled the mean in 'Scotland, N.,' but was much less elsewhere. In all the eastern and central parts of Great Britain the fall was scarcely appreciable.

"The bright sunshine was deficient in most parts of the kingdom, but exceeded the mean in some of the western districts, as well as in 'Scotland, N.,' on the one hand, and the 'Channel Islands' on the other. The percentage of the possible duration ranged from 34 in the 'Channel Islands,' and from 22 in 'Ireland, S.,' to 7 in 'England, N.W.,' 6 in 'Scotland, E. and W.,' and 4 in 'England, N.E.' The amount recorded at Jersey on Thursday was as large as 7.7, which is equal to 90 per cent. of the possible duration for that day, and that for the same day at Scilly was not much less."

ENQUIRY.

"He that questioneth much shall learn much."—BACON.

BRONZE OR METAL STATUES. Will any reader kindly furnish A. G. with the names and addresses of makers of bronze or other metal statues suitable for flower garden decoration?

NOTICES TO CORRESPONDENTS.

BOOKS: *E. B. S.* London gardening has no special features, and we know of no book dealing with it. There is a little work published at the Garden office, Southampton Street, entitled *The London Market Gardens: Flowers, Fruits, and Vegetables, as Grown for Market*, by C. H. Shaw.

CARNATIONS: *Malmaison*. Probably, eel-worms in the leaves; but we have not examined them with the microscope. We advise you to burn all the affected plants.

CARNIVOROUS AND HERBIVOROUS SLUGS AND SNAILS: Our correspondent, Mr. M. Webb, desires to supplement our remarks in our last issue with the information, that he received the micro-photographs, from which the figures were prepared, from Mr. F. Taylor, 38, Landseer Street, Oldham. For *Auloporna* read *Aulopoma*.

CELERY: *J. A. P.* The seed having been sown in March, no plant under proper conditions of cultivation would have "bolted." It had, as you suggested, suffered frequently from lack of moisture at the root, hence the crooked and small heads. Earthing-up was performed at, probably, an early part of the autumn; and Celery that has been blanched for so long a period of time is very liable to decay. Covering the heart-leaves in the act of moulding-up is a more rapid way of setting-up decay.

CHRYSANTHEMUM-RUST: *W. W.* There are various methods of dealing with this, but we think your employer is wise in recommending you to burn all the affected plants.

CLIMBING FERN: *W. H. Tillet*. The plant is probably *Lygodium scandens*. Can you send a frond for identification?

CROWN AND TERMINAL BUDS IN CHRYSANTHEMUMS: *Wilhelm Müller*. Your supposition is quite justified; the figure marked 49 should have been 59.

GARDENING PERIODICALS: *La Semaine Horticole*, published by M. L. Linden, in Brussels, is to be preferred to the one suggested.

GLASSHOUSE HEATING: *J. A.* Steam-heating is not injurious to plants, if no more be employed than will raise the temperature to the desired degree of warmth. The drying effects which the super-heated pipes have upon the air is readily obviated by damping the floors more or less. You might supplement the hot-water pipes by running a flow and return steam-pipe alongside of them, not through them. Care should be taken to employ either malleable iron tubing, or very strong cast-iron pipes with flange joints, well packed with vulcanised rubber, and run in with hot lead. One expansion piece of accurately-turned and polished pipe should be inserted in some part of the system, or in the case of cast-iron pipes, a rupture might occur.

GRAFTING VINES: *Vine*. You might place Foster's Seedling, or even Black Hamburgh, on Mrs. Pearson Vine and Alnwick Seedling, or Black Alicante on the White Tokay Vine. You may graft by approach, using the old wood, or young green wood on green shoots.

MARGUERITES: *G. F.* If by "maggots," the leaf-mining grubs are intended to be understood, there is no remedy that equals pinching them with the thumb-nail when observed. The plants should be closely watched so that the grubs do not spoil a lot of the leaves before they are killed. Sprinkling with quassia-water deters the fly from laying its eggs on the leaves.

MICROSCOPE: *H. H.* We do not know your qualifications. If you have not already had some instruction in the use of the microscope, or are not likely to obtain it, then it would be unwise to spend much money on an instrument you could not use. Your teacher would be able to advise you; meanwhile, any good optician in Edinburgh would furnish you with a student's microscope for £5 or £6. Less expensive instruments are of no use.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—*H. T. W.* 1, *Acacia Riceana*; 2, *A. dealbata*; 3, *Sequoia sempervirens*.—*Subscriber*. *Chlorophytum Sternbergianum*.—*C. P.*, *Arbroath*. 1, *Adiantum excisum*; 2, *Adiantum excisum multifidum*; 3,

Adiantum decorum; 4, *Grevillea* (next week); 5, *Cymbidium sinense*; 6, *Selaginella Mertensii*.—*J. R.* The plant is *Tainia latifolia*; the flowers of *Odontoglossum* are synanthic, united together.—*J. C.*, *Chesters*. *Dendrobium Dalhousieanum* flowering at an unusual time, and lighter in colour in consequence.—*Nosey*. *Solanum capsicastrum* of the variety which bears oval ascending berries, by the appearance of the damaged specimen received.—*W. T.*, *Cardiff*. So far as we can judge without seeing flowers, your plant is *Jasminum humile*, figured in *Bot. Reg.*, t. 350.—*J. C.* *Epidendrum ciliare*.—*J. T. L.*, *Belfast*. The single flower is *Epidendrum cochleatum*; the small spray, *Catasetum barbatum*.—*H. J. R.* We thank you for the letter containing remarks about *Stauroopsis*, and for promise of photographs of the two in question. The *Cypripedium* you send is certainly *C. praestans*. The hybrid much resembles *C. × Harrisianum roseum*, a variety obtained by crossing *C. barbatum* Warneri with *C. villosum*.—*C. B.* 1, *Adiantum capillus-veneris*; 2, cannot be determined without seeing a mature fertile frond; 3, *Cyrtomium Fortunei*; 4, *Veronica Andersoni variegata*. The other is *Juniperus sinensis*.

ORCHIDS, TIME OF FLOWERING: *Veritas*. *Epidendrum Godseffianum*, early summer; *Oncidium Gravesianum*, summer; *Zygopetalum Mackayi*, during the winter; *Laelia glauca* (*Brassavola*), February and March; *Vanda* (*Esmeralda*) *Sanderiana*, September and October; *Laelia majalis*, spring months; *Oncidium unguiculatum* is autumn-flowering. These plants may flower at other times, according to the treatment afforded.

RABBITS BARKING LARCH: *E. M.* We should certainly use the same composition as a safeguard, as was recommended in our issue for January 8 last for fruit trees.

SITUATIONS VACANT, &c.: *G. B.* We must adhere to our rule not to insert articles from unknown correspondents when sent under initials only. Kindly send full name and address, not necessarily for publication, but to establish your *bona fides*.

STOVE CONTAINING CROTONS, DRACENAS, EUCHARIS, CALADIUMS, AND USED ALSO FOR FORCING LILY-OF-THE-VALLEY, &c.: *W. E. L.* The temperatures given are too high in the winter months by 5° for the stove plants, although they might answer for forcing Tulips, Lily-of-the-Valley, Azaleas, and other subjects desired in bloom out of season. A temperature of 60°—65° at night, the lower reading in very cold or windy weather; and 70°—75° by day, the higher degree of warmth when the sun shines, would be more suitable for these and most other subjects used in conservatories. Lily-of-the-Valley will stand 85°—90° till the flower-stems are 2 to 3 inches high, when the crowns and clumps should be taken from the darkness in which they have been grown, and gradually inured to the light, and to a warmth of 70°, and eventually to 60°—55° or less when the bells are fully open.

VINES AND HOT-WATER-PIPES: *A. P.* No injury will be done to either.

WATER (SHOWER?) BOUQUET: *W. P.* We know of no work in the English language which affords instructions in bouquet-making, nor of any illustrations of a shower-bouquet, excepting one found in our columns, p. 339, September 21, 1895.

DIED.—On the 16th inst., at Tottenham, GEORGE BECKWITH, of the Tottenham Nurseries, aged 77.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,

MORE THAN DOUBLED, and that it continues to increase weekly. Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

(For Markets see p. xii.)

THE Gardeners' Chronicle.

SATURDAY, JANUARY 29, 1898.

HIMALAYAN RHODODENDRONS.*

HIMALAYAN Rhododendron culture in Great Britain may be said to have had birth concurrently with the publication of Sir J. D. Hooker's *Journals*. Until this intrepid explorer returned from his memorable travels in Sikkim, Rhododendrons were the exception rather than the rule in our conservatories, and few persons seemed to have thought that this beautiful class of plant was adapted to outdoor work.

The peculiar climatic advantages which the south-western counties offered for the cultivation of a tender vegetation were either not understood in those days, or, if understood, did not inspire sufficient confidence to induce horticulturists to introduce into their grounds many subjects which are now almost universally cultivated. Only within recent years has the barest justice been done to the favoured conditions under which gardening can be carried out; and it must be confessed that, in spite of what has been done during the past quarter of a century, much has yet to be accomplished before we can claim to be fully in league with Nature, or to have appropriated a tithe of the opportunities which our insular position and climate offer.

To say that the introduction of many of the tenderer forms of Rhododendrons instituted a new era in outdoor operations, is to assert what every student of the subject knows to be a fact. After a few of these noble plants had passed through half-a-dozen of our winters with but little or no injury, the scales fell from the eyes of the profession, and in an amazingly short time not only were most parks and gardens stocked with Rhododendrons, but the startling manner in which they evidenced the mildness of our winters led our gentry to carry the experiment to still more astonishing issues. Side by side now with the forests of Rhododendrons which are grown on many a south country estate, may be seen a sub-tropical flora embracing such children of a sunnier clime, as *Cobaea scandens*, *Daturas*, *Lapagerias*, *Cassias*, *Nicotianas*, the Citron, the Orange, the Banana, and a host of others which the gardeners of fifty years ago regarded as the aristocracy of the glasshouses.

To be frank, it must be confessed that it is only in the southern counties of England and Wales that such sub-tropical work can be carried on with anything like satisfaction, and that Rhododendrons find those requisites of

soil and climate which are so essential to their healthy growth. Nor is this surprising, when it is known that meteorological observations go to prove that the two westernmost counties have a climate in many respects superior to that enjoyed by the Riviera, and that plants which have been known to be killed off in severe winters in South France, pass through our own almost unscathed. In developing Falmouth as a winter resort, much importance has been attached to meteorological statistics. While admitting their value, it does seem to the writer that the evidence of the vegetation should carry a greater weight. Shy as the public ever are of figures, they cannot get away from the testimony of the flora; and of Nature's several ways of showing the geniality and equality of a climate, this is, by all the difference, the most reliable. To walk through some of our Cornish gardens from January to April, when our sweeps of Rhododendrons are tricked off in the most gorgeous of colours, is, for the time, to forget that one is in a small country where scarcely a winter passes without from 12° to 20° of frost being registered in some of the northern counties. Anything more beautiful than such collections of Rhododendrons as can be seen at Tremough, Tregothnan, Scorrier, Carelew, and Killiow, in Cornwall, can scarcely be conceived. Whether regarded from the standpoint of landscape gardening, valued for the length of their blooming season, or considered for the beauty of form and variety of colour of the individual flowers, we are obliged to confess, after a close acquaintance with these plants in Cornwall and South Wales, that they more than repay the time and money lavished upon them. The pity of it is, that in many places which might be named as admirably suitable for their cultivation they are relegated to a very subordinate position.

It is often urged as an objection against the culture of Himalayan Rhododendrons, that the earlier blooms are liable to be destroyed by the sharp frosts which are all too prevalent during the early spring. While granting the risk, it does seem like bolstering up a case with sham evidence to exclude the Rhododendron on such a pretext. If a few blooms are destroyed by frost, surely the display which follows later is a sufficient recompense for the labour; while the fact that, even in the severest weather, our Rhododendron walks are rarely without bloom from the middle of January onwards, is an ample set-off against the few buds that fall victims to the frost.

As far as Devon, Cornwall, and South Wales are concerned, it is, I think, quite probable that, in addition to the mildness of the climate, the humidity of the atmosphere greatly favours the Rhododendron. To the majority of them an over-dry atmosphere seems almost as fatal as a parched soil. This observation, which has been growing on me for years, finds plenty of evidence in its support in Sir J. D. Hooker's Himalayan journals.

Experience has taught me the wisdom of selecting a site fairly elevated but sheltered from high and cutting winds. In any case, low-lying and damp situations must be sedulously avoided, as they invariably spell ruin to the early flowers by their susceptibility to frosts. Northern aspects, where they enjoy a minimum of sunshine, and the shelter of a wall with a north exposure, have given us good results at Tremough.

While it is somewhat of a fallacy to say Rhododendrons will only flourish in a peaty soil, the fact remains, as anyone who has had

much to do with them can aver, that they are great lovers of peat in some form or other. If this is liberally administered to the soil when planting, the plants make a vigorous start at once. Granite sand in the proportion of one-third may be added to the peat with beneficial results. What they do not like is a limey or chalky soil, or a stiff water-logged clay. In our well-drained, gravelly loam at Tremough they root freely and luxuriantly, but I have known them grow almost as well on a properly-drained clay bottom. Being surface-rooting plants, it is obvious they will not stand prolonged droughts, so that in a very dry season the hose must be freely used in the shrubbery. Equally important is it to prevent the accumulation of superfluous and stagnant water around the roots. By way of protection against drought, the natural habit of Rhododendrons must be encouraged. Their lowest branches have a predilection for bending down so as to cover the roots; and if these branches be carefully preserved, and are encouraged, by the shade they offer, they will keep the soil around the roots comparatively moist in the driest season. Plants which fall the easiest victims to a dry summer are almost invariably those which have lost their lowermost branches, and whose roots are exposed to the full play of the sun.

PROPAGATION.

When we come to propagation, we touch a much-discussed problem, and here, again, I shall only speak from experience. While budding may commend itself to some, grafting to others, and layering to a third class, the raising of plants from seed, although confessedly a work requiring patience, has always been my own favourite method. In addition to the general interest connected with this process of stocking the garden, species raised from seed have the twofold advantage of being true to their kind, and of possessing robust constitution. Tremough may be cited in evidence thereof, the majority of the older plants there being raised from seed sent to my late employer, William Shilson, Esq., by Sir William Hooker. Of course, hard-and-fast lines cannot be laid down. Oftentimes one has to comply with temporary exigencies, when, if he is an advocate of raising seedlings, he will be obliged to have recourse to budding, grafting, or layering, and *vice versa*.

PLANTING.

The mode of planting-out which I have followed for nearly thirty years is to place the shrubs in specially-prepared pits, and to surround the ball of roots with a lining of peat and sand, to which I frequently add one-third of decayed leaf-mould. A surface-dressing is given as occasion may require. A good mulch of decaying leaves—Nature's own method of manuring—is a wonderful help to keeping the roots cool, but in kept beds and borders this cannot at all times be carried out, because of the untidy appearance it gives. In such cases, peat or fully-decayed leaves must be resorted to as a surface-dressing. In a paper read before the Royal Horticultural Society on June 6, 1893, Sir John T. D. Llewelyn, Bart., stated that a good top-dressing was to be found "in the dead last season's bracken Fern, which, if dry and well forked in, will be found very beneficial to the roots, and the stiffer the soil the more advantageous will it be, for it acts mechanically, as it were. Each stick or stem of Fern is a little hollow pipe forming a miniature subterranean tunnel, in which the delicate

* A paper read at the Devon and Exeter Gardeners' Association, Jan. 12, by Richard Gill, Tremough, Penryn, Cornwall.

Rhododendron rootlets can travel, and which afterwards, rotting down, affords nutriment to the growing root." Sir John may be correct when speaking for stiff soils, but, while admitting certain manurial virtues in the bracken, I should be driven to direct extremities before using it on ordinary free soils, fearing the results of this increased porosity in a dry season. In the application of top-dressing and in cleaning operations, the hoe and spade must be used with extreme caution. The best roots of the Rhododendron are near the surface, and to injure these is to damage the plant, in some cases irretrievably.

(To be continued.)

CRASSULA COLUMNARIS.

THIS is one of four species of *Crassula* which comprise the section *Pyramidella*. Plants of it were first sent to Kew in 1885 by Mr. C. J. Dunn, of Claremont, Cape Town, the discoverer of *Streptocarpus Dunni*. The photograph, of which an enlarged reproduction is given (fig. 23), was sent to Kew by Mr. A. J. Fuller, of Cape Town, who writes that the plant came from Matjesfontein, in the Karroo District. The entire plant does not exceed 3 inches in height. The stem is erect, and the fleshy orbicular obtuse imbricating leaves give it a quaint appearance, the whole plant resembling one of the *Balanophoræ*. The flowers are borne in dense capitate cymes, and are pure white.

Another closely-allied species is *C. pyramidalis*, a figure of which was published in the *Gardeners' Chronicle* in 1885, when there were plants of it in flower in the Cape-house at Kew, also received from Mr. Dunn. This species has closely imbricating leaves arranged in a four-angled prism of nearly equal diameter throughout. The longest stems are about 9 inches, but usually they do not exceed half that length. The flowers, which are dull orange-red, are borne in terminal heads, and on strong stems; they are also produced laterally. These two species deserve a place in collections of quaintly-attractive succulent plants. They require greenhouse treatment.

METHODS OF PROPAGATION.

(Continued from p. 427, vol. xii.)

BERRY-BEARING PLANTS.—The *Aucuba*, *Cornus* (Dogwood), *Cotoneaster*, *Pyracantha*, the *Date-Plum* (*Diospyros*), the *Privet*, and the handsome-leaved *Filaria*, are all raised from seed, either rubbed clean, pitted, or directly from the shrub when dead-ripe, or gathered and stored till the early spring, and then sown in boxes or pans, or even in beds in a cold pit, kept uniformly moist, the lights being closed at night, but open during the day. When the seedlings are large enough to handle, they may be either potted singly in small 60's, or five to ten in a 48, grown-on one season in shelter, and then lined up in the nursery beds.

The *Laurel Tribe*, being all Cherries, should have the pulp and skin cleared off the stones, or if time is no object, they may be pitted, and sown when the enveloping Cherry has decayed and left the stone clean. It must not be forgotten, however, that the finer varieties, as *Bertini*, *rotundifolia*, *caucasica*, &c., and some other broad-leaved hybrid forms, cannot be depended on to reproduce themselves true from seed, especially when the berries have been collected from a mixed shrubbery, as being hybrids, their tendency is to revert to the original type, therefore it is safer to layer or raise these from cuttings. This same caution also applies to the useful *Aucuba*, the varieties of which now number more than twenty distinct and useful sorts.

Leguminous plants, among which we find some very handsome shrubs, are easily increased by their small bean-like seeds, gathered just as ripe, and sown in the open border, or if in only small quantity, in boxes, pans, or pots. Many of these, however, have a trick of suddenly bursting their pods, and scatter-

ing the seed widely. Who has not stood on a Gorse-covered common on a still warm day in autumn, and heard the pods of the useful covert shrub bursting on all sides like the crack of fairy-rifles? The Brooms, Gorse, Carragana, *Amorpha*, *Bladder-senna* (*Colutea*) and other well-known Pea-flowering shrubs, are propagated from their seeds sown in boxes, pits, or the open border; these, like all the genus, quickly germinate, and being pricked out in the borders, soon make useful plants, but in all cases the tap-root should be taken out, leaving only the fibrous lateral rootlets, which renders the final transplanting both easy and safe.

Shrub seeds are catalogued and sold by most seedsmen, but it must be admitted that the sale, being limited and uncertain, fresh seed is rarely obtainable, and this mars success; therefore save your own, and sow as fresh as you can manage. This caution applies more cogently to the next class of subjects, namely, the beautiful Heath tribe (*Ericæ*), em-

The *Buddleas* can both be raised from seed in the same way, as also the *Carolina Allspice* (*Calycanthus*), the fragrant *Chimonanthus*, the European *Celtis*, and all the elegant-leaved *Sumachs* (*Rhus*).

The Japanese *Quinces* (*Cydonia*) are best increased by allowing the fruit to decay, and then taking out the pips and sowing them in pans, allowing the plant to grow from 6 to 9 inches high, and then cutting off the tap-root, potting singly, or quartering out in the nursery.

There are many more evergreen shrubs I have not specially mentioned, but all of them may be treated in one or the other ways I have endeavoured to indicate.

One final caution: never allow the soil covering any of these shrub-seeds to get dry, or just as the little radicle and plumule begin to push, they will perish, and your labour will be all in vain. *Experience*.

(To be continued.)

DO ORCHIDS DEGENERATE?

(Continued from p. 49.)

THE province of Malabar being well within the influence of the south-west monsoon, the rainfall, in consequence is very heavy, and the seasons are very distinctively marked. From March till June a few showers fall; about the 15th of the latter month the monsoon begins, continuing till about the 15th of September, and from the latter date till March comes round again the sky is clear and cloudless. In addition to the burning sun, a withering east wind prevails during the day from December to March, scorching all vegetation on the grassy hills and in the deciduous forests, which culminates in their being swept by fires before the advent of the first spring shower. The middle, or deciduous Orchid zone, being fully exposed to these trying climatic conditions, the *Dendrobiums* are seen hanging from the leafless trees on the hill-sides like dead things, and to the uninitiated it requires some exercise of imagination to believe that any effort of Nature could ever coax them into life again. The upper and lower, or evergreen Orchid zones, are no better off in the way of rainfall than the middle zone; but a wonderful compensating power prevails in Nature in the shape of heavy nightly mists or fogs during the hot months, yielding the necessary moisture, which is doubtless the cause of these plants choosing this zone as their natural home, where they can have the required amount of rest without any "drying off." It is curious to see in the same district *Saccolabium guttatum* clinging to the branch of an evergreen tree with leaves succulent and fresh, and then view the contrast at a very little distance and higher elevation of the pseudo-bulbs of the *Dendrobium album* withered and dangling in the hot east wind with relaxing root-hold, and in seeming danger of tumbling to the ground.

The fog, or watery vapour alluded to above, which is so much in evidence during the dry months of the year in the upper and lower belts, is a very beautiful sight when seen at day-break morning after morning from an elevated point clear of its influence. The country from the foot of the Western Ghats, extending to the Neilgherry mountains and across the Mysore frontier as far as the eye can reach, is covered with a mantle of fleecy clouds of the purest white, with the dark Bamboo-crowned tops of numerous cone-shaped little hills or elevations, peering out like so many fairy islands in a fairy sea. It is a sight, once seen, never to be forgotten. Underneath this fleecy pall flourish the evergreen Orchids, nightly receiving throughout the hot season at Nature's hands that gentle spray which speaks of showers to come, and

FIG. 23.—*CRASSULA COLUMNARIA* (SOUTH AFRICA).
(Above Natural Size.)

bracing the *Azalea*, *Rhododendron*, *Kalmia*, *Menziesia*, as well as the *Heaths* proper.

These are best raised in pans or boxes, with just enough crocks at the bottom to ensure proper drainage, covered first with a layer of fibrous peat, and filled up within an inch of the top with a fine sifted mixture of peat, loam, and sand. This should be pressed firmly down and well watered, then sow your seed evenly over the surface, covering over with fine sand, and cover over with a small square of glass, resting on the rim of the pan or box. Allow plenty of time for the seed to germinate, keeping a sharp look-out for any intrusion of insects, or what is more insidious, mossy or fungoid growths. Prick off the seedlings when they have made three leaves or more.

The brilliant *Azalea mollis* is an easy plant to increase thus, and gives us extraordinary variation in colour from seed, the *Rhododendron* in all its handsome varieties the same, but the other members of the genus are more constant from seed.

which refreshes them without disturbing their rest, which, in fact, supplies the necessary moisture they require to prevent a "drying-out." These fogs are wonderfully defined. They hang along the base of the middle-zone in a beautifully distinct line, leaving the middle-zone clear; whilst higher up may be seen clouds of the same fleecy nature rolling up the ravines and gorges of the mountains, and disappearing gradually as the sun gains power. Now, supposing for a moment that a col-

lector entering such a district similar to that I have been attempting to describe, and forwarding to England a consignment of Orchids gathered indiscriminately, with a statement in general terms that the plants were procured from a certain district possessing a certain climate characterised by so many months of dry weather and the other months of the year showery and wet, with no other information whatever regarding the less noticeable climatic peculiarities, which probably are as numerous and various all over the world as the districts from which Orchids are drawn. In such a case the probabilities are

that the recipient of such a consignment, in the absence of information of such vital importance, would make cultural mistakes resulting, perhaps, in the death of a large percentage of the plants. It would seem therefore, that a great responsibility rests with the collectors, and it might be well for the future of Orchid culture in England, and contribute to the checking of that deplorable annual mortality which undoubtedly takes place among imported Orchids, were employers to insist upon collectors

FIG. 24.—A BUNCH OF COOPER'S BLACK GRAPES, GRAFTED ON GROS COLMAN.
(SEE P. 71.)

lector entering such a district similar to that I have been attempting to describe, and forwarding to England a consignment of Orchids gathered indiscriminately, with a statement in general terms that the plants were procured from a certain district possessing a certain climate characterised by so many months of dry weather and the other months of the year showery and wet, with no other information whatever regarding the less noticeable climatic peculiarities, which probably are as numerous and various all over the world as the districts from which Orchids are drawn. In such a case the probabilities are

sending with each consignment the fullest particulars regarding the climatic conditions under which the plants were found growing in a state of nature. Collectors are men of undoubted intelligence, so that there would be no difficulty in the way of their affording such information.

That cultural mistakes are made at the present day even with Orchids and other plants that have been in England for a great number of years, is a fact that should not escape comment. *J. Lowrie.*

(To be continued.)

THE DEGENERATION OR DEATH OF ORCHIDS.

HAVING of late been consulting old records in reference to hybrid Orchids, it occurred to me that many names seemed to be now only names, the plants that bore them have gone; at any rate we rarely if ever hear of many whose names I append. I have therefore made a list of some that are not seen either in the notices in the horticultural Press, neither do we see them at the Royal Horticultural Society. It may be that many are yet alive in quiet collections where Orchids are grown like other plants, because they have beautiful blooms that are used as cut-flowers only. If this communication does unearth some of them it will have attained its end. *Cattleya Aclandi* × *Loddigesii*, *C.* × *Brabantia*, *C.* × *Dominyana* alba, *C.* × *D. lutea*, *C.* × *hybrida* (*C. guttata* × *C. Loddigesii*), *C.* × *picta* (*C. guttata* × *C. intermedia*), *C.* × *picturata* (*C. guttata* × *C. intermedia*), *C.* × *flaveola* (*C. guttata* × *C. intermedia*), *C. labiata* leucophæa, *C. Mendeli* Lendyana, *C. Mossiæ* Marianæ, *C. M. McMorlandi*, *C. labiata* Pitcheri, *C. Trianaei* Cleopatra, *C. T. Io*, *C. T. Juno*, *C. T. Venus*, *C. T. splendidissima*, *C. Lindeni*, *C.* × *Lowryana*, *C.* × *Manglesii*, *C.* × *Mitcheli*, *C.* × *quinquecolor*, *Lælia albida* Stobartiana, *L. a. sulphurea*, *L. anceps* Percivalliana, *L. a. Calvertiana*, *L. a. obscura*, *L. a. leucosticta*, *L. a. radians*, *L. a. Leeana*, *L. a. Veitchiana*, *L. a. holochila*, *L. flammea*, *L. purpurea*, *L. purpurata* nobilis, *L.* × *Pilcheriana*, *L.* × *Pilcheriana* alba, *L.* × *Sedeni*, *Lælio-Cattleya* × *Devoniensis*, *Odontoglossum aureo-purpureum*, *O. crispum* apiculatum, *O. c. aureum*, *O. c. a. magnificum*, *O. c. Bowmanianum*, *O. c. pendulum*, *O. c. Perrini*, *O. c. Mrs. C. Dorman*, *O. c. Regina*, *O. c. Rothschildianum*, *O. blepharicanthum*, *O. cinnamomeum*, *O. Dennisoniæ*, *O. eugenes*, *O. flavescens*, *O. hystrix* Denisoniæ, *O. intermedium*, *O. Lowryanum*, *O. macrospilum*, *O. luteo-purpureum* illustre, *O. mulus* Bockett's var., *O. maculosum* superbum, *O. Pescatorei* Jackson's var., *O. P. melanocentrum*, *O. P. Mrs. G. W. Palmer*, *O. P. Tilgate* var., *O. Rossii* F. L. Ames, *O. Scottii*, *O. triumphans* Marshallii, *O. t. nigrescens*, *O. t. Wilsonii*, *O. Roeblingianum*, *O. Wilckeanum* Cooksonianum, *O. Wendlandianum*, *O. rigidum*, *O. retusum*.

I have only taken three genera, and were the list amplified by specialists in *Cypripedium*, *Dendrobium*, and other genera, it would be far larger. In addition to these, there were a great many plants named by Reichenbach that one never hears of now. Where are they? All these originals had their day and made their stir, each at its time, now the majority are but a name.

Does such a list suggest the broad fact that Orchids passed from hand to hand die owing to various cultivators treating them in different ways, going from place to place, and having to exist under vastly different conditions? Plants grown for many years in one place and always cultivated by the same hands can be found all over the country, in some cases going back for twenty-six years. *de B. Crawshaw.*

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Peaches and Nectarines.—The pruning of these fruits, now that the buds are swelling, should be commenced, for if the weather continues mild, the trees will soon be in flower. The fruit being borne on wood of last season's growth, the fan-system of training is the best, much of the growth not required for extension being removed before it has got large enough for extensive wounds being caused by its removal, which rarely heal. The young shoots should always start from the upper side of the old branches, it is then an easy matter to fill up gaps when these occur, as the other branches can be pulled downwards, and shoots encouraged in the centre. This arrangement depends very much on the sort of summer-pruning pursued; but if the young shoots have been laid-in on the under-side of the branches these shoots should be removed where they can be spared, and thus, in two or three seasons, the faulty system of laying-in on the under or both sides can be

corrected. Any unripe shoots should be shortened back to ripe wood, always letting triple buds terminate the shoots. Well-ripened shoots may be trained in at full length if there is space, especially at the extremities of the branches if further extension is allowable. Bearing wood should be laid-in at not less than 4 inches apart.

Cleaning.—Before the trees are nailed or tied, let them be thoroughly syringed with a solution of soft-soap, at the rate of four ounces to a gallon of rain-water, dissolved in boiling water and diluted to the above strength. Every part of a tree and the surface of the wall must be wetted with the soap-suds and allowed to dry on. If brown scale should exist, let it be removed by means of a thin strip of wood from the older branches, and with a sponge from the tender rind of the young wood, the latter requiring great care, the scale insects being small and not easily seen, and the buds are easily rubbed off. The syringing of the trees with soap-suds may only be carried out during mild weather.

Training.—When nailing or tying, leave space for the younger branches to swell, for most of them will be double their present size by next autumn; and look carefully after the old ties and shreds that they are not so tight as to cut into the rind. Tying is perhaps more dangerous in this way than nails and shreds; moreover, the latter, by securing the trees closer to the wall, enables them to obtain more protection from the wall, and is therefore better suited for gardens in the Midlands and the North.

Protection.—The remarks on the Apricot (p. 55) apply also to the Peach and Nectarine, and need not be repeated here.

The Fruit-room.—Such late varieties of Pears as Beurré Rance, Olivier de Serres, Bergamot d'Esperen, and Ne Plus Meuris, are much improved in quality if placed in a temperature of 55° for a few days before consuming them, putting them in boxes with a little wood-wool or paper shavings beneath and between them. Apples, on the contrary, should be kept as cool as possible this mild weather, being careful to remove every decaying fruit as soon as observed, and to guard against a sudden rise of the temperature, which would cause moisture to be deposited on the fruit, and in that way hasten decay.

THE ORCHID HOUSES.

By W. H. WHITE Orchid Grower, Burford, Dorset.

Angræcums and Zygopetalums.—Plants of *Angræcum sesquipedale* that have done blooming should now be repotted or top-dressed, as previously advised for the *Aërides*. *Angræcum eburneum*, now in flower, may be similarly treated after the spikes are cut. *A. pellucidum*, now producing its long drooping flower-spikes, that have a tendency to push themselves down into the compost, should be examined daily, it being sometimes necessary to assist the spikes over the surface by placing a piece of tile or crock under them. This plant should always be protected from sunshine, or the foliage quickly changes colour; keep the plant well supplied with water until its flowers have opened. The rare terete-leaved *A. Scottianum*, being of semi-scandent growth, succeeds best when trained to upright rafts or cylinders, the stems tied firmly to the rods, so that the small roots may have something substantial to cling to. Whilst in active growth, the plant should be syringed once or twice daily. *A. Leonis*, now sending up its flower-spikes, should be watered moderately only. Instead of dipping the plant in the usual manner, it is better to use a fine-rose watering-can and to lightly sprinkle the surface of the moss and around the side of the basket occasionally. Plants of *Zygopetalum Mackayi* and its variety *crinitum*, that have recently passed out of flower, may be repotted or top-dressed should they require it. A mixture of fibrous loam, chopped moss, and plenty of broken crocks well mixed together is a suitable compost. Place the plants on the shady side of the warm-house, and take the usual care not to over-water newly-potted plants. *Z. maxillare* extends its creeping rhizome several inches annually, so that it is useless to try to subject it to pot-culture; it grows naturally upon the stems of Tree-Ferns, and it is usually imported so. In the case of plants which have overgrown these stems, a fresh piece of Tree-Fern should be wired on to the original, and the plant will soon take hold of the added portion; this should be attended to at once, as the plant will be starting into growth. Water must be freely given at all times. *Z. maxillare* should be grown in a moist, shady corner of the *Odontoglossum*-house; when grown in a warmer temperature it is generally injured by insect-pests.

Cypripediums.—Any plant of the following, *C. purpuratum*, *C. Schlimii*, *C. Leeannum* ×, *C. Arthuri-anum* ×, *C. venustum*, *C. Mastersianum*, *C. Williamsii* ×, *C. Amesianum* ×, *C. Crossianum* ×, *C. Sallieri-Hyeannum* ×, *C. insigne* and its varieties, that have become pot-bound, should be repotted as they pass out of flower. Strong, healthy specimens may be shifted into pots at least two sizes larger than they are in at present. The pots should be one-third filled with drainage, secured by a layer of sphagnum. Lumpy peat and sphagnum-moss in equal parts, and pieces of crock or broken limestone mixed with it, will grow to perfection any of the above varieties. All of them thrive luxuriantly in a shady part of the intermediate-house. When the new roots are in full activity, abundance of water must be afforded. *C. Schlimii* is a plant that does not appreciate strong light, under which its foliage turns to a sickly hue, but a piece of tissue-paper spread over the leaves will protect them from harm. Plants of *C. Boxalli* and *C. villosum* are producing their flower-spikes, which should be guided through the foliage, or they may be distorted through the opposition of the heavy leaves. Both species require the temperature of the intermediate-house.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Bougainvillea glabra and Varieties.—After a period of rest in a cool-house, any which are now shedding their foliage may be somewhat severely pruned back, removing all weak shoots, and very strong ones if these be not required for furnishing the plants. The strong shoots needed for building up the plants should also have the unripened wood removed from them. Keep the plants dry at the roots till they start into growth, taking care the wood does not shrivel from over-dryness of the soil.

Clerodendron Balfourianum.—Plants which have been rested may now be started in a brisk heat, applying slight bottom-heat if possible. If the plants are grown in large pots, it will suffice for several years if the surface-soil be replaced with a rich compost, making it firm. If repotting be necessary, the plants should first be started into growth. Care must be taken of the fibrous roots, and as a potting-soil use fibrous loam two-thirds, leaf-mould and coarse sand one-third, and well-rotted manure one-seventh. The plants should be kept rather on the dry side before and for some time after repotting, syringing them till root-action commences, when a little more water will be required, increasing the quantity as time progresses. Plants at rest must not be placed in a house having a lower temperature than 55°, or they may fail to start.

Plumbago capensis.—These are plants secured to pillars and walls in the conservatory or greenhouse; the annual shoots may be pruned back to two or three buds from the base, and where space can be afforded for extension, a less severe cutting back and shortening of the stronger growths will suffice. Plants growing in pots may be cut back, and then placed in heat to yield cuttings for next year's stock. If the plants are infested with thrips, let them be cleansed with an insecticide before growth begins.

Azalea indica.—The early forced plants of *Deutsche Perle* which have gone out of flower should be placed in an early vinery or Peach-house, and syringed freely to encourage growth. Any that require repotting may have immediate attention. Later flowering plants require to be kept cool, and to be thoroughly syringed when the weather will allow, fumigating the house if thrip be present on the plants. Water must be afforded with great care, and only when it is really wanted; on the other hand, dryness at the root is fatal to these fine hair-rooted plants.

Carnation Miss Joliffe.—If there is a deficiency of this variety, than which few are more useful in the winter, cuttings may be inserted forthwith, taking young growing shoots from plants grown in a cool-house, which must be cut close to a joint with a very sharp knife, and inserted round the side of a small pot to the number of two or three, using sandy soil, affording a thorough application of water, and placing the pots under a hand-light or bell-glass, giving them bottom-heat of 75° to 80°, and top-heat of 65°. Other varieties may be treated in a similar manner. Last autumn layers that were placed in small pots will now be well rooted, and they may be potted into small 60's, and stood in a cool-house or frame, protecting them from frost.

Gardenias.—Those plants which are showing flower-buds should have the shoots which are pushing

out near the base of the flower-bud removed. The plants delight in abundance of heat and moisture, and the syringe should be freely employed till the flower-buds commence to open, when atmospheric moisture should be considerably reduced. If mealy-bug infect the plants, petroleum emulsion or methylated spirits-of-wine should be applied, the latter with a small brush.

Cannas.—Those plants that are required for decorative work and have had a thorough rest may be divided, and the bits placed in pots according to their size, when, if plunged in a fairly brisk bottom-heat, they will soon begin to grow, and in about a month may be removed into cooler quarters. If a good number be cultivated, they should be divided into batches, to form a succession. It is not a safe practice to prolong the drying-off period over three months.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

Leeks.—In order to obtain large well-blanching, and mild flavoured stems, a sowing of *The Lyon*, *Sutton's Prizetaker*, and *Dobbie's Champion*, should now be made in boxes or seed-pans, filled with rich, light soil, scattering the seeds thinly, and covering them with $\frac{1}{2}$ -inch layer of fine soil; and afford a temperature of about 50°. When plants appear, keep the boxes, &c., near the glass till pricked off; meanwhile the boxes for this purpose should be got in readiness by filling them with a compost consisting of equal parts loam, leaf-mould, and spent Mushroom-dung, also adding sharp sand, pressing the compost firmly, and placing the boxes where the soil may get warm. When the plants show two leaves is the time to transplant them at 2 inches apart. Do not admit much air to them before they have begun to grow, and afterwards the same kind of treatment as that advised for the raising of big-bulbed Onions will suit the plant in its early stages.

Winter Spinach.—Let the ground be stirred with the hoe between the rows, choosing a day when the soil is dry for doing the work. Seeds of round or of the prickly-seeded Spinaches may now be sown on a south border, affording the plants protection during frosty and cold weather by means of spare frame lights, dry bracken, or litter. For early sowings the drills may be drawn flat and shallow at 15 inches apart, and the plants singled out to 4 inches from each other, a greater distance being unnecessary with so short-lived a plant.

Parsnips.—A piece of deep, rich land, which should have been trenched in the autumn, and no dressing of manure afforded, may now be got in readiness when the land is in a comparatively dry state. After forking it over a few inches deep, and scuffling it so as to obtain a fine tilth, and raking and levelling it, divide it into beds 5 feet wide, sowing the seed in drills 1 inch deep, and 1½ foot apart for big sorts, and 1¼ foot for smaller ones. As Parsnips require a long season of growth, the seed should be got into the ground in February. *The Hollow Crown*, *Student*, and *Dobbie's Champion* are the best, the first two for exhibition.

Peas.—The early sowings of Peas and Broad Beans, when the tops are above the ground, should have small live pieces of Spruce Fir or other evergreens stuck into the soil close up to the rows, and traps should be set for mice, which are in some gardens destructive to early Peas and Beans. As a further protective, damp all seeds of Peas and Beans before sowing, and coat them with dry red lead, or scatter Furze-tops passed through a chaff-cutter along the drills before closing them.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

New Borders.—Continuing my remarks on Figs in last week's issue, I now give some brief directions on making indoor borders. If it be the intention to plant Fig-trees in the spring, the border may now be prepared for their reception; and as the Fig is more fruitful in borders of limited size than in large ones, a border 5 feet wide, with 1 ft. of drainage materials, and a depth of soil of 1½ ft., is sufficiently large to enable good size trees to flourish. The bottom should be concreted, making it fall to a point, where a drain may take away the water that percolates through the soil. The front or the back-wall of the house may form one side of the border, and a wall of brickwork or concrete 2½ ft. high the other side built at the edge of the concrete bottom. A suitable

APPOINTMENTS FOR FEBRUARY.

THURSDAY,	FEB. 3	—Linnean Society.
TUESDAY,	FEB. 8	{ Royal Horticultural Society's Committees.
SATURDAY,	FEB. 12	{ Royal Botanic Society's General Meeting.
THURSDAY,	FEB. 17	—Linnean Society's Meeting.
FRIDAY,	FEB. 18	{ Annual General Meeting of Royal Gardeners' Orphan Fund.
THURSDAY,	FEB. 24	{ Annual Meeting of Kew Guild at 8 P.M.
SATURDAY,	FEB. 26	{ Royal Botanic Society's General Meeting.

SALES FOR THE ENSUING WEEK.

		Lilies, Azaleas, Roses, Greenhouse Ferns, &c., at Protheroe & Morris' Rooms.
		Clearance Sale of Plants, Garden Tools, &c., at The Priory, Wim- bledon Common, by order of R. S. Dean, Esq., by Protheroe & Morris.
TUESDAY,	FEB. 1	Great Clearance Sale of well-grown Fruit Trees, at Lee's Nursery, High Road, Ealing Dean, by order of Messrs. Chas. Lee & Sons, by Protheroe & Morris (three days).
		Japanese Lilies, Continental Plants, Spiræas, Gladioli, Roses, Ane- mones, &c., at Protheroe & Morris' Rooms.
		Clearance Sale of Nursery Stock, Carts, Tools, &c., at the St. Martin's Nursery, Canterbury, by order of the Executors of the late Mr. J. Kennet, by Protheroe & Morris (two days).
WEDNESDAY,	FEB. 2	Rose and Fruit Trees, Shrubs, Plants, Palms, Bulbs, &c., at Mr. Stevens' Rooms.
		Miscellaneous Bulbs, Carnations, Lilies of the Valley, Roses, &c., at Protheroe & Morris' Rooms.
THURSDAY,	FEB. 3	Liliums, Border Plants, &c., at Mr. Stevens' Rooms.
FRIDAY,	FEB. 4	Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from
Observations of Forty-three years, at Chiswick.—39° 2°.

ACTUAL TEMPERATURES:—

LONDON.—January 26 (6 P.M.): Max., 48°; Min., 44°.
PROVINCES.—January 26 (6 P.M.): Max., 51°, south-
west Ireland; Min., 48°, north-east Scotland.
Weather dull, mild, and foggy.

The annual meeting of this Institution was in progress as we went to press last week; nevertheless, we were enabled to lay before our readers the substance of the report, and the results of the ballot. Briefly it was stated that the "Diamond Jubilee" year had proved the most successful on record. The total number of pensioners up to the end of last year was 167, and the amount of money bestowed is, in round numbers, £3000 yearly; but withal, there were as many as twenty-nine unsuccessful candidates at the preceding election, and on the present occasion thirty-four.

Success and practical experience may be held to justify the existing methods of procedure with regard to the distribution of votes, the more so as measures have been lately devised in the interests of those candidates who do not happen to have influential friends, and consequently have less opportunity of accumulating votes than their more fortunate, but probably not more deserving, competitors.

A legacy left by the late W. J. THOMSON, a well-known gardener, formerly of Kew, and lately a nurseryman, was also devised on the same lines, and came into operation on this occasion for the first time. Mr. THOMSON, it appears left a sum of money to be so applied, that the widow who obtained the highest number of votes among the unsuccessful candidates at any election shall be admitted to the benefits of the Society. We could wish now that some legator would now provide means for the election of the lowest on the list.

The allotment by the committee in certain cases of a number of votes, and the establishment of the Victorian Era Fund show that the Committee is alive to the evils of the present

system, and is desirous to mitigate them as far as possible.

In favour of the plan now practised, with all the expense and trouble it entails on the candidates or their friends, and the unfair preference shown to non-subscribers, it is alleged that the subscribers set store upon the privilege of voting, and would think themselves deprived of their rights if some other plan were introduced. Two circumstances tell against this view, one, that the accidental income, if we may so call that derived from, or in consequence of the annual dinner is greater than that derived from the gardeners for whose benefit the Society exists! This is a most lamentable and discreditable state of things, and we venture to say no society can be in a satisfactory state so long as it exists.

The second indication is shown in the fact announced by the scrutineers, that more than 1100 votes were spoiled because the voters cared so little about the matter that they did not sign their names to the voting papers, or omitted to comply with some other formality.

We are thankful to say that the invested sums amount to no less than £30,000, a sum which the Treasurer spoke of in somewhat deprecatory terms, as if it were too large; but so long as there is this disquieting disproportion between the amount contributed by annual subscribers—gardeners, and that raised by other precarious means, so long is a large reserve fund absolutely necessary to meet contingencies which may arise, however much we may desire that they may not do so.

There are considerably more than six thousand head-gardeners in the British Isles. Let us suppose that these six thousand contributed ten shillings each, the amount so obtained would about pay the amount now annually distributed; and the donations of the friends of the Society, and the contributions of younger gardeners according to their means, would allow of a considerable reduction in the number of unsuccessful candidates each year.

As we have said, some further arrangements are needed to secure the most equitable distribution of votes. The Society has staunch friends, and an able committee imbued with but one thought—the benefit of the disabled gardener or his widow. Already they take great responsibility—a little more would not add materially to their trouble. Let the Committee, who know so much more than any one else of the necessities of each case, select each year the names of candidates they suggest for election, and submit them for approval or rejection to the general meeting. Personal canvassing and circulation of cards should be discouraged as much as possible; but each subscriber would have the right to object to all or any of the names selected by the Committee, and to substitute other names from the list of approved candidates according to the amount of his donations or subscriptions as at present.

DATURA SUAVEOLENS.—The fine-looking specimen represented in our illustration (fig. 26), is a species that has long been an inhabitant of our gardens, and one that requires but simple treatment. The plant was photographed in September, as it stood in the centre of the conservatory at Thelwall Heys, the residence of W. LONG, Esq., near Warrington. Mr. POULTON, the gardener, sent along with the photograph the following particulars in regard to the plant: The Ferns and Palms were arranged around it in order to hide the tub in which it was growing. The height of plant from the top of the tub was 5 feet, and the number of blooms open at the time was 300. For the space of about a fortnight it was a very fine sight, especially of an

evening, when its pure white flowers were full expanded, and gave off a delicious fragrance, which was strong enough to be perceptible at some distance away from the conservatory. This species of *Datura* does well if afforded one good shift each year, and an occasional top-dressing of rich compost, and it should never be allowed to suffer from lack of water during the growing season. After blooming, it is pruned severely, stored away in a Peach-house, keeping cool and dry till growth re-commences in the spring.

LINNEAN SOCIETY.—On the occasion of the evening meeting, to be held on Thursday, February 1898, at 8 P.M., the following papers will be read, viz., 1, "On the Muscular Attachment of the Animal to its Shell in some Fossil Cephalopods (Ammonoidea)," by Mr. G. C. CRICK, F.G.S., F.Z.S., 2, "The Comparative Anatomy of certain genera of Cycadaceæ," by Mr. W. C. WORSDELL, F.L.S.

VEITCH MEMORIAL TRUST.—At a meeting of the trustees, held on January 19, Dr. MAXWELL MASTERS in the chair, it was unanimously resolved that medals for objects to be hereafter determined should be allotted for the present year, at exhibition to be held at Bristol, Leicester, and Cardiff respectively. A sum of £20 was voted to the trustees of the Lindley Library towards the preparation of the catalogue now in progress. Medals were also allotted to M. MARLIAC, in recognition of his success as a hybridiser; to M. ED. ANDRÉ, of Paris; and to M. le Comte DE KERCHOVE, of Ghent, President of the Royal Agricultural and Botanical Society of Ghent for their respective services to horticulture.

ROYAL BOTANIC SOCIETY.—A meeting of the Fellows of the Royal Botanic Society was held on Saturday afternoon in the museum at the Society's gardens, Regent's Park. Mr. C. E. LAYTON presided and there was an unusually large attendance. Four new Fellows were elected, including Dr. COLLINS, Chairman of the London County Council, and nine were nominated for election at the next meeting. Professor HENSLOW read a paper on "Plant Variations," which he illustrated by means of a large number of photographs reflected upon a screen. He described the various monstrosities, or departures from the normal structure, of different plants, and traced in many cases the gradual transition from the original to the "sport," showing how the character of the latter had become fixed or hereditary and was now looked upon as quite the normal form.

BORSODORF REINETTE OF DOBERAN.—Under this name, says Dr. Dammer, a new variety of the well-known Borsdorf Reinette was shown by Gartenbau-director MATHIEU the doyen of German pomology at the last meeting of the Berlin Horticultural Society. The plant was raised from seeds of the common Borsdorf Reinette by Count FINK at Doberan in Mecklenburg. It resembles the mother plant perfectly as regards the fruit, taste and flavour, which, as well as size, are quite the same, but there is more red colour upon its surface. The genuine form of the Borsdorf Reinette has one fault: it begins to fruit very late; the trees at 20-25 years old before they begin to flower. But what fruit-grower can wait so long a time in our epoch of steam and electricity? Gartenbau-director MATHIEU has proved the new variety, and upon his authority, it may be said, that it is an early-fruiting one. That it is a very fine acquisition for our orchards as the Borsdorf Reinette is esteemed as the best apple of all.

BRITISH SEEDS ABROAD.—Messrs. JAMES CARTER & Co., of 237, High Holborn, write on the subject as follows:—"On p. 58 you invite testimony as to the work of British seed houses abroad. We may state that we have published catalogues of French for over forty years [with metrical weights &c.], and on various occasions have issued special lists in German, Russian, Swedish, and Spanish. Our own travellers go regularly to every part of the world where seeds are in demand. In respect to seeds going to outlandish places, we may state that we have lately sent a quantity to the Island of Tristan d'Acunha, a lonely spot in the South Pacific Ocean; and we also send at regular intervals to Pitcairn Island, where both vegetable

FIG. 26.—*DATURA SUAVEOLENS* IN THE GARDEN OF W. LONG, ESQ., THELWALL HEYS, WARRINGTON: FLOWERS WHITE, FRAGRANT. (SEE P. 70.)

and flowers are greatly appreciated by the descendants of the mutineers of the *Bounty*. Only last week we were commissioned by the officer commanding the military expedition now in Uganda (Central Africa), to prepare a large assortment of seeds for growth at the headwaters of the Nile, when they reach there. A box of our seeds for cultivation in the Virgin Islands formed one of seventeen parcels received by the Post-office during the last twelve months. On another occasion recently we were required to forward some seeds to a country not included in the Postal Guide, and had several formalities to go through before the Post-office would take charge of the package. From these items it may safely be said that our seeds go to the uttermost parts of the earth as pioneers of civilisation. We believe we are the only seed house that issues a work on gardening giving world-wide information, the second edition of which has just been issued, all available copies of the first print having been bought up by a Colonial Government."

— Messrs. HURST & SON, of 152, Houndsditch, E., remark:—"Referring to your note on British seed catalogues for foreign circulation, permit us to say that we have for the last twenty-five years not only issued catalogues in foreign languages, but have sent out a representative, who has travelled regularly between Norway and Sweden and the extreme south, even to Algiers. Latterly the French Government have done their utmost to destroy this trade by imposing a heavy duty, and by refusing to accept any evidence of the English origin of such seeds as Peas, even declaring that no Peas are grown in England, despite sworn testimony to the contrary. Other countries—Norway, Sweden, and Denmark—demand a heavy license-fee from foreign commercial travellers, endeavouring by that means to prevent competition."

DR. HULIN, who acted as president of the party of Belgian horticulturists when they favoured us with a visit in 1883, has recently died at Ghent at the ripe age of 86. Belgian papers speak of him as the friend of the poor and of the labourer.

NEW YORK BOTANICAL GARDEN.—One of the last events of the old year was the beginning of actual construction-work upon the New York Botanical Garden, an event which cannot but be fraught with importance, and we hope productive of incalculable good. On December 31, 1897, President McMILLAN of the Department of Parks, on being presented with a new pick and shovel by Messrs. PARKER & PARSHLEY, of the JOHN H. PARKER Company, contractors, formally started the first work on the museum building. There were also present Dr. N. L. BRITTON, Director-in-Chief of the New York Botanical Garden; Mr. JOHN I. KANE, of the Board of Managers; Dr. JOHN K. SMALL, of Columbia University; Mr. LEONARD BARRON, Editor of *American Gardening*; Professor A. H. DUNDON, of the Normal College; Mr. SAMUEL HENSHAW and Mr. GEO. V. NASH, of the staff of the New York Botanical Garden; and others. The pick and shovel used on this occasion will in due course be deposited in the museum building.

GARDENING IN EGYPT.—Mr. WALTER DRAPER is about to publish a book devoted to gardening in Lower Egypt, and treating of the climate, soil, laying-out of the garden, suitable trees, shrubs, climbers, Roses, Palms, succulents, vegetables, &c.

A EUROPEAN FORSYTHIA. — Dr. ANTONIO BALDACCIO has discovered in Albania a shrub differing but little from the Chinese *F. suspensa*, save in the shorter petioles. We shall hope shortly to see living specimens at Kew; for however interesting may be the fact from the point of view of botanical geography, it is still more so to witness the "bird in the hand" at Kew.

NEWSVENDORS BENEVOLENT AND PROVIDENT INSTITUTION. — The fifty-ninth annual general meeting will be held at the Memorial Hall on Tuesday, February 15. President, the Right Hon. Lord GLENESK, will take the chair at 7 o'clock precisely. The annual festival dinner will be held at the Hotel

Cecil on Wednesday, May 11. Mr. CECIL B. HARMSWORTH will preside, and his brothers, the Messrs. ALFRED and HAROLD HARMSWORTH, with many other friends of the Institution, have promised to attend this gathering.

NEWCASTLE-ON-TYNE FLOWER SHOWS.—We have received a copy of the schedule of the above. The spring show will be held in the Olympia on Wednesday and Thursday, April 20 and 21, 1898. The summer show will be held in the Recreation Ground, in conjunction with the Northumberland Agricultural Show, on Wednesday, Thursday, and Friday, July 13, 14, and 15, 1898. The Royal Horticultural Society's Council, as has already been noticed in these pages, have accepted an invitation to be present, and will send a deputation with full powers to make awards. The attendance at the last joint show in the year 1893 was enormous, and the financial result was a very successful one. Copies of the schedule may be had from the Secretary, 54, Westgate Road.

THE LONDON WHOLESALE FRUIT AND POTATO TRADES' AND GROWERS' BENEVOLENT SOCIETY.—The annual meeting of the Society will be held at the Tavistock Hotel, Covent Garden, on Tuesday, February 1, 1898, at 6 P.M. The Society is still in its infancy, but has a balance in hand of £231, investments to the amount of £2492 11s. 1d., and distributes in pensions £138 10s.

FRUIT FROM THE CAPE.—The authorities at African House, Bishopsgate, E.C., inform us that fruit from the Cape, per Union line of steamers, are now on their way here, and may be expected to arrive in about a week's time. It is to be hoped that an improvement may this season be shown in the samples submitted to auction.

PEOPLE'S PALACE HORTICULTURAL SOCIETY.—Another of the series of popular lectures on gardening was delivered at the People's Palace, Mile End, on Saturday Evening, the 22th inst., by Mr. RICHARD DEAN, V.M.H., on "The Life History of a Flower," illustrated by the florist's Tulip. There was as usual a large attendance of members, coloured diagrams being employed, while all the technical terms were plainly written on a black-board and explained. After a brief history of the flower, and a passing allusion to the Tulipomania, a diagram of a flower was shown with its seminal organs, and the process of fertilisation explained; a diagram of a seed was shown, the method and time of sowing given, with illustrations of that singular characteristic of the seedling Tulip, the production of "droppers." Coloured illustrations of the breeder stage were shown, then the flamed and feathered characters, with other characteristics of the flower, the lecturer winding up with an account of the procedure of a Tulip-show in Cheshire. Details of culture were supplied, and an effort was made to interest the audience in a flower which was at one time grown for exhibition in several parts of the east of London. A hearty vote of thanks was passed to the lecturer. The first of four flower-shows during the year will take place on March 31.

"THE CULTURE OF VÉGÉTABLES AND FLOWERS FROM SEEDS AND ROOTS:" SUTTON & SONS, READING. (SIMPKIN, MARSHALL, HAMILTON, KENT & Co., London.) The seventh edition of an eminently practical hand-book, wherein, in reasonable compass, are directions for the culture of vegetables and flowers in the garden, with instructions for the year's work therein. There are also chapters on the chemistry of garden crops, on lawn and tennis-grounds from seeds, on the pests of garden-plants, fungus-pests of garden-plants, and those of certain flowers. The principal parts of the book are alphabetically arranged, and the addition of an index renders the desired information still more easy to find. Of the reliability of the cultural and other directions it is scarcely necessary to speak.

VIOLA MRS. ASTOR.—The managers of the Hood Gardens, Totnes, enclose a few blooms of Mrs. J. J. Astor, a new American Violet. The colour, a

reddish-lilac, is novel and pretty, being darker than Madame Millet, and the plants are, we are told, more vigorous than that variety. It is very free-flowering, and seems to be an early bloomer. We cannot say much in favour of the perfume.

ROBERT BEGBIE returns his heartfelt thanks to those subscribers to whom he is indebted for having placed him by their votes on the pension-list of the Gardeners' Royal Benevolent Institution on the 20th inst.

WILLIAMS' MEMORIAL MEDAL.—At a recent meeting of the Williams' Memorial Trustees, Dr. Masters in the chair, it was decided to offer two Silver Memorial Medals at the summer show of the Royal Botanic Society to be held in May next, and two Silver Memorial Medals at the York Gala to be held this year.

PUBLICATIONS RECEIVED.—*Report upon the Essex Field Experiments during 1896-97.* These trials were undertaken at the instance of the Essex County Council, and the results are here carefully tabulated: 1, Manurial trials on Beans followed by Wheat; 2, Manurial trials on permanent pasture; 3, Experiments on laying down land to grass; 4, Manurial trials on Oats followed by Mangolds.—*Twenty-first Annual Report for 1897 of the National Auricula and Primula Society* (Southern Section). This leaflet announces the gratifying fact that the past season has been the most successful for many years, owing to a large accession of new members and a consequently improved financial position.—*The West Australian Settler's Guide and Farmer's Handbook*, Parts II. and III. Issued by direction of the Bureau of Agriculture. Valuable for intending or established colonists. Part II. is devoted to the Settler's Outfit, Clearing, Ringbarking, Cultivating, Farm Book-keeping, &c.; Part III. to Native Grasses and Fodder-Bushes and Plants, Special Products of the Farm, Tobacco, Sugar-Beet, Rape, Potatoes; laying down land to grass, noxious weeds, and native poison plants.—*Report of the Botanist L. R. Jones, from the tenth Annual Report of the Vermont Experiment Station* (1896-97). The more important subjects under discussion were: Potato diseases and remedies, Orchard diseases and remedies, Observations upon Oat Smut, the Onion-mildew, and the Orange Hawkweed or "Paint Brush."—*Unique Journal Horticole Japonais* (Journal of the Japanese Horticultural Society), April and November, 1897.—*Dictionnaire Pratique d'Horticulture*, 66th Livraison. This publication is advanced as far as the word *Spigelia*.—*Liste des Graines recoltées par le Jardin alpin d'acclimatation, Genève*. H. Correvon, Janvier, 1898.—*Index seminum in horti Musei Parisiensis anno 1897 collectorum*. From M. le Directeur du Muséum d'histoire naturelle, Paris.—*Katalog der Bibliothek des Vereins zur Beförderung des Gartenbaues* (Berlin, 1897).—*Illustrierte Flora* (Jänner, 1898).—*Illustrierte Nützliche Blätter* (Jänner, 1898).

THE PITCULLEN VINERIES.

THE fair city of Perth and its environs are celebrated for picturesque beauty and smiling plenty. Years ago, this town was famed for its luscious Jargonelle Pears, some of the finest of which were grown within the city's boundaries. Others were found

on the Bridgend and Belwood side of the Tay. These ancient trees of Jargonelle almost certainly whetted the appetite for horticulture that so greatly enriches the Tay bank opposite the North Inch to-day. On this charming site the merchants of Perth have built their palatial homes, and planted their miniature parks and their gardens. The scene must be actually seen for its beauty to be duly appreciated. Probably, it is not excelled in these islands or elsewhere. Others beside bumptious Scotchmen have compared the beauty of the Tay at Perth with that of the Tiber at Rome. In three points, the verdure of the grass, the stateliness and extent of its timber, and the charming environment of the surrounding mountains, the Tay may match the Tiber.

I am still conscious that we are in the land of the mountain and the flood; the land of brown Heath and shaggy fell; yet here we have a fullness and softness of picturesque beauty by no means common to Scottish scenery. It is, therefore, no matter for wonder that we find many fine estates in the near neighbourhood, to wit, Dupplin, Moncrieffe, Methven, Drummond Castle, Scone, Athole. And the majority of the gardens that adorn the banks of the Tay are mellowed with age, as well as enriched with a great variety of new plants and trees. Broadly stated, the gardens at Pitcullen, the residence of A. Coates, Esq., are bounded with timber trees, that afford shelter and shadow, enabling the pedestrian to find pleasant walks in the grounds in all kinds of weather. By carrying the walks round under the trees, introducing shrubs, Ferns, and flowers at different points, freshness, interest, and variety are provided. Still further, variety is gained by planting groups of Roses, beds of flowering plants, extensive stretches of lawn, and fine solitary trees, and groups of them.

Neither do the fruit trees and flowers, nor the vegetables in the kitchen garden, seem to suffer from the proximity of the big trees. The larger part of the garden lies on falling ground; the crops out-of-doors and the fruits under glass are pictures of good health and fertility. The land on which Pitcullen Gardens stand culminates, about three miles off, at the Hill of Kinnoul; from which the Carse of Gowrie is seen, with the Tay meandering to the sea. The higher parts of the grounds command charming views of the landscape to a point beyond Scone Palace. Although Scone is my native place, I had never seen so much of the beauty of the district as can be seen from Kinnoul Hill.

THE VINERIES.

Those who visit Pitcullen at once recognise in Mr. Leslie, Mr. Coates' gardener, an able, all-round cultivator, and most gardeners will often have heard of Leslie, of Pitcullen, and many have observed his exhibits of first-rate Grapes. May I linger on the threshold of a very unique range of vineries to say that Mr. Leslie has three houses filled with Peach-trees; also Melon and Tomato-houses, stove and greenhouse, fernery, &c., in all of which the inmates were in excellent trim. His Grapes have in recent years been observed at most of the best shows in Scotland, winning for him the highest prizes at Edinburgh, Glasgow, Dundee, and other towns. The Vines showed at the time of my visit clusters of Grapes perfect in every point. To walk through vineries filled with Vines carrying fine foliage and bunches of perfect finish is alone an instructive treat. The first glance of the five Pitcullen vineries is rather disappointing. The massive character of their construction is lessened a little by the peculiarity of the site, which obliged the builder to erect them on different levels; and being less than half-spans, they look too lofty, but not top-heavy. The fact is, the five vineries, ranging from 30 to 47 feet in length, are erected on a sloping brae of considerable height, and each is 18 inches higher than the one lower down the slope. When the eye gets used to the effect, it is as pleasing as unique. Entering from the lowest level, the clusters of Grapes seem to grow in size, and in density of colour and bloom.

These vineries are 17 feet high, and 14 feet wide.

The glass-sashes in the front are 4 feet high; the front rafters have a run of more than 17 feet, and those at the back of 7½ feet. There can be no question that this form of vinery affords the Vines much light, and facilitates ventilation, as is testified by the vigour of the Vines, and the size and finish of the bunches.

The vineries are of the same dimensions as regards width and height throughout, and differ only in length. The Muscat-vinery is 47 feet long; and in bunch, berry, leaf, wood the Vines are all that could be desired. The next house is 30 feet long, and is furnished with Black Alicante and Gros Maroc

more than twelve years, for young Vines are substituted for aged ones as occasion requires, well as new vineries built.

The depth of the Vine borders is about 33 inches. The width of the outside borders 7 feet, and 9 feet that of the inside border. The total width inside the vineries is 14 feet, disposed of as follows:—Nine feet for border, against the front wall, the Vines being planted within 7 inches of the wall; the distance between the Muscat Vines being 5 feet, and between other varieties 4 feet. The path occupies 2½ feet in width, and under this the hot-water pipe-mains are carried, branches going off wherever

FIG. 27.—A BUNCH OF BLACK ALICANTE GRAPES. (SEE P. 71.)

varieties, these Grapes looking all the blacker for their proximity to the Muscat of Alexandria in the next vinery. The other three vineries forming the half-span range are also 30 feet long in each case; the third vinery contains Gros Colmar Vines with big berries with a bloom on them like that seen on Plums; the fourth is a Black Alicante vinery, and the fifth or earliest is furnished with Black Hamburgs and Madresfield Court varieties, which were doing as well as the thicker-skinned hardier kinds.

Besides this range, there is also another narrower early vinery that is 30 feet long and 10 feet wide, furnished with Black Hamburgs, and yet another 50 feet long and 13 feet wide, that was planted with Gros Colmar in 1896. There is no sign of decadence in the older Vines, most of which have been planted

they are wanted. The remaining space of 2½ feet forms a border for Vines on the back wall. No doubt the conditions of this border in regard to drainage, composition of the soil, provision of root-food, &c., are all that skill can suggest or money provide, yet Mr. Leslie rejoices in the fact that many of his Vine-roots have been found straying away into the kitchen-garden quarters, a distance of 18 yards from the borders; and no attempt seems to have been made to limit the Vine-roots to the borders either outside or inside. As to Vine-manures, for many years the only artificial stimulant has been Cross's Vine-manure, which has given complete satisfaction.

One thing was soon noted, viz., the tops, as well as the roots, have more freedom than in most cases.

Mr. Leslie's canon of pruning may be put into a nutshell: cut back to the most promising bud on the lateral rather than to the bud that is closest to the main rod; and this especially in the case of Black Alicante and Muscat of Alexandria. The Vines in return for this freedom yield bunches and berries of wood of abnormally fine quality.

The figs. 24, 25, and 27, are given as mere samples of the Grapes grown at Pitcullen, as may be seen by noting fig. 27, that of a bunch of Alicante, weighing 13 lb. 6 oz., grown there last year; also a bunch of Cooper's Black or Gros Maroc of about 3 lb. in weight (fig. 25). Both of these show perfect finish, although neither illustrates the average size of those fine varieties.

The two figures of bunches of Gros Maroc or Cooper's Black (figs. 24 and 25) confirm the opinion held by Mr. Leslie and other growers, that they are one and the same thing. In this case, the photograph of Cooper's Black was obtained from a gardener who declared it to be quite distinct from Gros Maroc, and the bunch to have grown on a scion that was grafted on a Vine of Gros Colman. The Gros Maroc at Pitcullen has been grown on its own roots for fourteen years. Mr. Leslie's verdict is that the two varieties are identical, or at any rate the foliage, bark, length of stalk, character, form, size of bunch, are so much alike that no difference can be detected, and the flavour is identical. Hence, possibly horticultural societies at future shows will refuse to admit Cooper's Black and Gros Maroc as distinct varieties; and this popular market Grape will in future be known as Gros Maroc. Mr. Leslie was good enough to give his emphatic testimony in favour of Mr. Kirk's Vine Border Tester.

This article does not tell one half of the story of these famous graperies and their skilful management. D. T. Fish, 12, Fettes Row, Edinburgh.

A GARDEN TOOL.

THE implement represented in fig. 28 is a very useful one in gardens, and more particularly on soils that are light or gravelly, as an alternative for the hoe, stirring the soil to a greater depth, being also equally expeditious; it should find a place in every garden. I am informed it is made in three sizes (the figure shows the smaller size). It is the invention of a fellow member of the craft in New Zealand, where it is evidently appreciated if one may judge by the testimonials to hand. It will be gathered from the picture that the tines rotate at an equal rate, hence it is continuous in its action. The patentee is Mr. A. Hosking, Manawatu Foundry, Palmerston, North, N.Z. J. Hudson.

HOME CORRESPONDENCE.

ORNITHOGALUM LACTEUM.—I have on my table a bloom of a pretty but not common flower, which I brought from the Cape, and which was cut on November 28. It is still quite fresh and sweet. It is *Ornithogalum lacteum*, known by the Kaffirs as "Chittering Chee," and is well known in the colony for its wonderful vitality, lasting in bloom until its smallest bud is fully developed. I quite expect it to last for another week, making nine weeks in all since it was gathered. *Francis Fox, F.R.H.S.* [We have had blooms of this species in water for three months. They were also cut in S. Africa. See *Gard. Chron.*, Dec. 23, 1893, p. 780. Ed.]

WORM-EATING SLUGS.—I am indebted to Mr. Henry Lavers, of Colchester, for the following reply to my enquiry, how slugs ejected from *Testacellæ* are observed to be partly cut asunder at distances of about an inch apart: "I think the lingual teeth of all *Testacellæ* are suitable for cutting; they are a series of sharp points, each of which must when drawn across the worm, cut a furrow which would very quickly sever the worm. I know that if you hold one in your fingers it will quickly turn and bite your skin, and draw blood very soon, and a very nasty sensation it is too." *W. Thomson, Bishops Teignton, South Devon.*

THE GARDENERS' BENEVOLENT ELECTION.—I cannot of course tell what may be the general opinion

of subscribers to this fund in respect of the recent election of pensioners, but to me it is exceedingly disappointing. It has become a stereotyped sermon or aspiration with all who refer to the fund, and advocate its claims, that gardeners ought universally to become subscribers that they may thus have prior claim on the fund's benefits, and provide themselves in their old age with a pension. That is a splendid doctrine, admirably calculated to encourage thrift and self-dependence. What is the outcome of it? I turn to the result of the recent election as reported in your pages last week, and find that out of the nine pensioners elected by the ballot, no fewer than five never have been subscribers at all! Is not that at once putting a premium on thriftlessness, and disregarding common care for the future in sickness or old age? What a different and nobler doctrine the United Horticultural Provident and Benefit Society practises! Being most desirous that my few votes should not be wasted, I gave them to a candidate who had already to his account nearly 2,300 votes, was 76 years of age, and had been a life member for seven years! Naturally I expected that such an old and worthy candidate must be elected. Judge of my surprise on finding not only that he was not, but that two others, both 66 years of age, or eight years younger than the other, and one starting with but 400 votes and the other with 751, were elected. I may be told it is all the chance of the ballot, but that won't do for me.

FIG. 28.—A REVOLVING CULTIVATOR.

Admittedly both these latter were two out of the four subscribers elected, but why favour men only 68 years old over one 76 years of age, and having such an envious start in votes? In a previous letter to the *Gardeners' Chronicle*, I pointed out that out of the 44 candidates 23 were subscribers or the widows of such, leaving 21 non-subscribers. The result is to give distinct encouragement to non-subscribers, by electing five out of the lesser or non-subscribing lot, and four only out of the greater or subscribing lot. That is practising what chairmen at banquets and dinners are being constantly coached to preach, with a vengeance. Of the candidates, I have personal knowledge of one only. Most of them elicit one's deepest sympathy, having been subscribers several years. Such candidates as Nos. 4, 6, 15, 20, 32, 34, 40, 41, 43, if none be dead before next year's election should all be made pensioners, and doubtless would be did every subscriber fill and sign his voting-paper himself, according to his unbiassed judgment as to the merits of each case. One other fact is worthy of mention: out of the six highest on the poll, only one was a subscriber, and that only for five years, commencing at the age of 70. Is it, indeed, not time that only subscribers of at least five

years should be eligible to become candidates? I should have added, that whilst the man who had nearly 2,300 votes had been a candidate five years, the one starting with 400 had not previously been, and the 757 candidate once only. *A. D.*

MARKET REPORTS AGAIN.—I notice in the market reports that Marguerites have been quoted all the summer, and are so now, at 2s. to 4s. per dozen bunches. I only obtained 5d. per dozen for the same flowers in early autumn. *W.*

A HALL FOR HORTICULTURE.—In the discussion of this subject, one of your correspondents writes: "Mr. Dean recommends Mr. Divers to try a show in London depending upon the gate-money to reimburse the outlay. No sane person would attempt such a scheme, but to some extent such show would depend on subscriptions."—Why should such a show not succeed in London? In other places success has been emphatic and permanent. In connection with the Chrysanthemum shows of the Scottish Horticultural Association, there are practically no subscriptions or donations; the members' annual subscriptions of 2s. 6d. are applied to other purposes, and with the exception of £20 generously voted as a special prize by the Magistrates and Town Council of Edinburgh, and a few donations as special prizes by various tradesmen, amounting to about £50 (inclusive of the City donation), the whole prizes and expenses of every description are paid from the gate-money and a small sum received as rents of sale stalls, and for the right to publish the show catalogue. As everybody knows, the prizes offered are on the most liberal scale, and the amount spent on decorations, music, hospitality, &c., are by no means parsimonious. We believe in the best of music, but do not descend to a concert-room or ballroom as mentioned by your correspondent H. Nichols. The results have been of the most gratifying description. A sum of about £500 having been given in charities during the eight years the shows have been carried on in the Waverley Market, from the surplus funds, and the Association have a balance in hand as a reserve fund of nearly £700. Surely what has been done in Edinburgh could be done in London. We look to the metropolis for light and leading on most subjects, and it is difficult for an outsider to understand why an exhibition got up on popular lines, and carried through with spirit, should be impossible there. Of course, the Waverley Market in Edinburgh is peculiarly suited for such exhibitions, standing in the very centre of the city, and having ample space for a public promenade. It may be, too, that entertainments of every description are so numerous in London that a flower-show by itself may seem tame, and yet it would seem that, to many of its teeming multitudes, such a show would be a welcome relief. Mr. Dean, as representing the Committee of the National Chrysanthemum Society, probably knows difficulties not apparent to outsiders, as, doubtless, the subject has received careful discussion; or, is it that the National Chrysanthemum Society, like a child commencing to walk, is so afraid to trust its own legs, that it clings to something it imagines stronger than itself for support? *M. Todd, Edinburgh.*

WATER-BOUQUET.—In "Notices to Correspondents" in to-day's *Gardeners' Chronicle*, I see an answer to an enquiry about a "water-bouquet," which shows that the question has not been understood. May I therefore say that a water-bouquet is made in the following manner:—Take a stone of as rough a surface as possible, tie on to it the flowers and foliage of your bouquet, such as scarlet Pelargoniums and Maidenhair or Asparagus. Lower the stone carefully on to a dish, which you have placed in a bathful of water; then place a glass-shade, such as are used for wax-flowers, &c., over the flowers on the dish, being careful to put it down sideways, so that it is completely filled with water, excluding all air, and then gently bring the dish up with the bouquet under the glass-shade upon it. The flowers will last thus for weeks. *A. G. B.*

TREES AT MOTTISFONT ABBEY.—In answer to "A. D.," in last week's issue, respecting the ancient Oak-tree, I may say it is still existing, and doing fairly well. This grand old pollard Oak measures 35 feet in circumference at 3 feet from the ground, and at 6 feet is 33½ feet. There is still an entrance to the interior, the hollow of which is 19 feet in circumference, but the entrance is gradually getting smaller. With respect to the large Plane-tree which stands on the lawn, near the bank of the river, the roots are like net-work in the bed of the river, which, no doubt, is

the secret of the tree's success. There are several other fine Planes growing here, measuring over 20 feet in circumference. *H. G. Reed, Mottisfont Abbey Gardens.*

VIOLAS.—I am not disposed to take much notice of this controversy between the Rev. Dr. Williamson and Mr. W. Sydenham, but I think it worth pointing out that Mr. Williamson's article almost in its entirety is based, so far as the merits of varieties for bedding purposes are concerned, upon the Report of the Viola Conference, Royal Botanic Gardens, August 7, 1896, whereas Mr. Sydenham's opinions are his own. Not one of the varieties Mr. Sydenham names is included by the conference committee in their lists. I enclose a selection which may be of service to intending buyers, in view of the approach of the planting and purchasing season:—

Report as to the Inspection of the Viola Trial, at the Royal Botanic Society's Gardens, August 7, 1896.

The committee next proceeded to make selections of the best varieties of different types and colours, dividing them into two main sections:—Firstly, dwarf-growing, having close, compact, tufted habit; and secondly, those of a taller and more spreading growth, well adapted for association with other plants which would afford them a certain amount of support:—

<i>Dwarf.</i>		<i>WHITE.</i>	<i>Tall.</i>
Niphetos, syn. Marchioness	Countess of Hopetoun	Countess of Wharcliffe	Gigantea
Pencatland	Snowflake		
<i>CREAM.</i>		Abington	Nellie
Sylvia	Lemon Queen		
<i>PRIMROSE, OR SULPHUR.</i>		Sulphurca	
Ardwell Gem	Luteola		
<i>DEEP YELLOW.</i>		Mary Gilbert	A. J. Rowberry
Princess Louise	Lord Elcho		
Bullion			
<i>DARK BLUE, OR VIOLET.</i>		Archie Grant	Max Kolb
True Blue	Mrs. C. Turner		
<i>BLUE.</i>		Ivanhoe	
Roland Graeme			
<i>LIGHT BLUE.</i>		Favourite	
Diana	Blue Gown		
<i>LAVENDER, OR LILAC.</i>		Duchess of Sutherland	Bridegroom
Rosea pallida	Lottie McNeil	Mabel	
<i>PURPLE.</i>		J. B. Riding	Dorothy Tennant
Acme	Mrs. Gordon		
<i>ROSE.</i>		William Niel	Rosine
Princess Ida	Rose Queen	Magie	
<i>BLUSH.</i>		Charm	Norah May
<i>EDGED, OR BORDERED.</i>		Cissy Thornley	Colleen Bawn
Duchess of Fife	Border Witch		
Blue Cloud			
<i>FANCY.—COUNTES OF KINTORE TYPE.</i>		Countess of Kintore	Isabel Spencer
The Mearns	Bethune	Princess Beatrice	Lady Amory
Cissy Mellows	Columba	Mr. H. Bellamy	
<i>STRIPED.</i>		Lilly Langtry	H. W. Stewart

The Committee responsible for the selection was: Messrs. A. J. Rowberry (Chairman), J. F. McLeod, Wm. Cuthbertson, C. Jordan, J. W. Moorman, George Gordon, and Richard Dean (Secretary). Surely a strong and representative lot of gentlemen. *Anglo-Scot.*

THE PRUNING OF APPLE AND PEAR TREES.—

Permit me to reply to Mr. Hott's queries. Apple and Pear trees, all things being favourable, raised from buds or grafts, even if they make 7 feet of growth, will emit shoots, in garden parlance "break" regularly, and these take an outward direction, and a fruiting specimen is soon found. Headed-down trees have a more or less upward tendency in their branches, which they keep till the weight of fruit bends them to the semi-horizontal position; and the Blenheim Orange Pippin, by not fruiting so early as, for example, Devonshire Quarrenden, grows more rigidly upright for a much longer period than the latter, until ultimately it has also to bow its branches as the more fruitful period sets in. Permit me also to say "J. K." does not presume to teach "old hands," for he is himself still a student of Nature, and, unlike many growers of to-day, whose early life was spent under glass, he has closely studied hardy fruits, and paid much attention to what has appeared on the subject in the pages of the *Gardeners' Chronicle*. I find that pruning to a certain given number of

inches will not always work; soils, kinds of stocks, and localities, have varying effects on growth. For instance, Pitmaston Duchess on the Pear stock, side by side with another on the Quince stock that are five years old, had 8 feet of growth, whilst the other had only 3 feet, yet both bear fruit, and one does not make much growth. In another soil the one might not fruit at all, and the other bear heavily. My objection to the pruning of young trees is, that it tends to multiply the branches close home, which may look very well then; but as the tree ages, they will mainly have to be taken off, for the chances of getting any fruit on them will then be very remote. *J. K., Wimborne.*

BELGIUM.

PLANTS AT L'HORTICULTURE INTERNATIONALE.

I NOTED here a fine specimen of *Saccolabium giganteum* album, with a raceme of very pretty pure white flowers; it is probably the only example of this remarkable variety to be found in Belgium. Very handsome also was *Cypripedium Arthurianum*, with twenty-eight blooms.

A very interesting introduction is that of twelve thousand specimens of *Cattleya labiata* excelsior, which will be valued because they flower in November, December, and January. This introduction followed that of *C. Warocqueana* (*C. labiata autumnalis*), from a district hitherto unexplored. I was interested also in some hybrids between *Cypripedium spectabile* and *C. villosum*, which is probably the first cross obtained between an open-air and a greenhouse variety. *Ch. De B.*

MARKET GARDENING.

A PIONEER "GROWER."

THE decease of Mr. Geo. Beckwith, which was briefly announced in our last issue, has removed from us one of the most energetic of the pioneers in market garden cultivation under glass. It is forty years or more since Geo. Beckwith, Philip Ladds, Rochford (father of the present generation of Rochfords), and others first engaged in the work, and the trade was then in its infancy. Sanguine indeed would have been any man to have guessed at that time the enormous extension of the system that has since taken place.

The following particulars of the life of the deceased, courteously given by his surviving son to a representative of the *Gardeners' Chronicle*, may be of interest.

Early in the forties, deceased, at the age of 22, was employed by the firm of Howard, manufacturing chemist at Stratford, and at this place he did a good deal of plumbing and mending of leaden tanks. For five years he practised this work, and at the expiration of that time Mr. Beckwith, who was specially good at mechanics, commenced business for himself as a hot-water engineer. He remained at this business for nearly ten years, during which time he provided and fixed hot-water apparatuses in plant-houses, and made iron-work used by the horticultural builder. Eventually he was forced to leave the premises, owing to the authorities building a sewer through the site, and forty years ago he took the "White Hart" at Tottenham. His energy was by no means exhausted in the management of a public-house, and he soon began to consider how best to utilize an area of four acres of land at the rear of the premises. Partly from his previous experience, and it may be also the advice of an old neighbouring florist, he built a plant house, and having made it pay, he raised another and another. Tricoloured Pelargoniums were the sensation in the horticulture of those days, and no one admired them more than Mr. Beckwith—they were his hobby. He grew Pelargoniums almost exclusively for the first few years, including Tom Thumb, and other varieties. Then for several years he was so engaged with the tricoloured sorts that each of the houses was given up to them. The propagation and sale of the plants

brought excellent returns, and much money was made. A new van being built at the time, its exterior was decorated by representations of the famous foliage. "Shortly before this period," said Mr. Beckwith, "I was just about to complete my apprenticeship to the smith's trade, and my father wrote to me, saying that if I was agreeable to take to market gardening, he would build other houses and make a business of it." This was done, and father and son then worked late and early to establish a business, and both of them being skilled mechanics, house after house was erected in a large measure by their own hands, boilers invented to suit their special needs, and success won. But Tottenham to-day is not the Tottenham of thirty years ago, but the effect that increasing smoke would have upon the cultivation of plants was foreseen many years ago. In 1885 about ten acres of land was acquired at Hoddesdon, near Broxbourne, and the late Mr. Beckwith's energy again applied to the building of first-rate houses, in better fashion than those at Tottenham. During the thirteen years there have been fifty built, and the last was only added in 1897. We cannot stop to describe them at any length now (though possibly we may refer to them again). In several respects they are unique. There are no brick walls, but the iron rafters which form the span are bent in three places: at the summit, and on either side, which consequently provide straight sides, and they are then embedded into walls of concrete. Concrete, iron, and glass, constitute the buildings, and few market nurseries have been built in a style approaching this for durability. It may be added that each house is 300 feet long by 20 feet wide. The building was done exactly after the ideas of the late Mr. Beckwith, and only four years ago, at the age of seventy-three, he sustained a fall of some 20 feet from a scaffold, when superintending some of the work. Little has been done of late to renovate the Tottenham houses, and the land, together with the "White Hart," will probably be disposed of in the near future, and the firm's business transferred entirely to Hoddesdon.

During the forty years deceased was engaged in market gardening he witnessed many and marvellous changes in the

PLANTS CULTIVATED,

in the prices obtained for produce, and in Covent Garden itself. But our note having already become longer than we intended, it must suffice to refer very briefly to a few of fashion's effects upon the industry. Though the remarkable decline in hard-wooded plants affected the late grower less than many others, as he never made a specialty of Ericas, it forced him to give up the cultivation of several plants popular at the same time as were Ericas. Camellias were once profitable, and realised 6s. a dozen blooms, but they have been thrown out long since. Cinerarias and Chinese Primulas in a large measure have shared a similar fate. Gardenias no longer give the returns they did, and Eucharis cultivation has been perforce abandoned, because the 10,000 plants that were once a paying item, gradually but surely dwindled away.

In the cut-flower trade, a serious fall in the price of Hyacinths, Tulips, and other bulbous flowers, has almost ruined this branch of the business, and, excepting Narcissus, Lily of the Valley, and Japanese Lilies, the forcing of bulbs has been nearly dropped. But market-gardening still pays handsomely if the best means be adopted to cultivate the varieties of plants or flowers the public most demand. The whole of the houses at Hoddesdon are devoted to the growth of flowers for cutting, the principal plants being Roses in pots (some 200,000), Lilies of the Valley; Raspail Improved, and other zonal-leaved Pelargoniums, also the so-called decorative Pelargoniums, Pancratiums (which pay capitally), and Chrysanthemums. In respect of Lily of the Valley, Mr. Beckwith paid £3000 for crowns for forcing this season. Tomatoes are grown largely as a late crop when the Roses have been placed out-of-doors in the summer, and bedding-plants are grown in large numbers. More than 100 workmen are employed in the two nurseries. Such is the business that the late Mr. Beckwith and his

have established, and it is worthy of remark that its success has followed the efforts of two men, neither of whom had any knowledge whatever of the cultivation of plants until they had embarked in the business. "But," said deceased's son, "father was an extraordinary enthusiast, a most ingenious man, and as good a mechanic as I have ever met."

After suffering the greater part of last year, Mr. [Name] succumbed somewhat suddenly on the 16th inst., to "Bright's disease," at the age of 77.

SOCIETIES.

READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

JANUARY 17.—Under the auspices of this successful horticultural Association, a tea and smoking-concert was held in the Abbey Hall (by the kind permission of Messrs. Sutton & Sons) on Monday evening. Nearly one hundred members sat down to tea, which was presided over by the President, Mr. C. B. STEVENS. The tables were decorated with plants, &c., from the gardens of East Thorpe (Mr. Woolford, gr.), &c., among the company present were Mr. Leonard G. Sutton, Mr. M. H. F. Sutton, Messrs. T. Turton and J. [Name], Chairman and Vice-chairman respectively of the Association for the season 1898; Messrs. J. Pound, Junr., J. Martin, Woolford, Smith, Dockerill, Chamberlain, Jones, Wright, F. G. Cox, Spencer, Parsons, Neve (Sindlesham), Townsend (Wellington College), Barfoot, Thatcher, Castle [Name], Rigg, Pound Senr., Farey, Fixter, Hobbs (Caversham), Dearlove (Burghfield), Lacey, Wagstaff (Bearwood), W. H. Cox (Calcot), &c.

"Strawberries from Seed, or the Cultivation of the Alpine Strawberry," was the subject of a paper read by Mr. JAMES HUDSON, of Gunnersbury House Gardens, before the members on the 24th inst.

In the discussion which followed the reading of the paper, the members taking part had to plead ignorance of the cultivation of the alpine Strawberry, but hearing what the lecturer said in its favour, and the fact that a dish of Strawberries during September and October would be a great addition to the dessert, they will no doubt give the plant a trial. Mr. Hudson said: the culture is of the simplest, and even weight for weight upon the same space of ground, the alpine will not be one whit behind that of the average crop of other Strawberries. The French grow their stock from seed, and it is only within the last few years that English firms have catalogued the seed, although the plants from runners are, as a rule, offered in most of our Strawberry lists in a similar way to the large-fruited varieties. This plan of offering the runners instead of the seed tended against any extended culture. After dealing fully with the system of cultivation carried out at Gunnersbury, the speaker gave much valuable advice as to soils and their adaptability for growing alpine Strawberries, also the position most suitable. The two varieties best for general cultivation are Royal Amelioré and Sutton's Large Red Alpine, the former producing fruits 2 inches long, whilst the latter, although not quite so large, is equal to it in every other respect, and with some it would be preferred because of its more handsome shape. Other varieties worth growing are Belle de [Name], colour of the deepest red, and flavour first-rate; Berger Improved, a variety very highly thought of by French growers; and Large White Alpine, which on account of its colour makes a pleasing change for the dessert. A box containing some 120 to 140 spikes of well-grown Lily-of-the-Valley, many of the spikes having fourteen and fifteen bells each, was shown by Messrs. Rigg & Fixter, The Nurseries, Caversham.

ROYAL METEOROLOGICAL.

JANUARY 19.—The annual general meeting of the Royal Meteorological Society was held on the above date, at the Institution of Civil Engineers, Great George Street, Westminster. The chair was taken by Mr. E. MAWLEY, President of the Society.

At the conclusion of the routine business, the President delivered an address on "Weather influences on farm and garden crops." He emphasised the close connection existing between meteorology and agriculture, observing that it had been found at the experimental farms at Rothamsted that the difference between a good and bad season in regard to weather might mean double the amount of produce. So intimate was the connection that, given the detailed weather records for any year, it would be almost possible to trace the effect of different seasons on different kinds of products. Great Britain was remarkably free from extreme changes of weather, which mainly accounted for the fact that such a large number of plants could be grown with success, and that the British Isles contained probably a larger number of indigenous species than any other country of the same extent. The effect of temperature on the growth of plants was very marked. Each kind of plant had its own requirements with regard to temperature both by day and night.

That fact should induce farmers in this country to grow only those crops which had been found to be best suited to the climate and temperature. The influence of rainfall on vegetation was second only to that of temperature. The fall of rain in these islands was more than sufficient for the wants of cereals, but it was very often too little, and seldom too much, for root-crops. Percolation and evaporation were also to be taken into consideration. The fertility of land was lowered when the drainage was excessive, owing to the loss of nitrogen. A deep fall of snow in the winter months should be welcomed by the farmer. It kept the ground comparatively steady in temperature, and afforded a protection against severe frost. The British Isles were undoubtedly better for grazing cattle than for raising wheat, which required for complete success a greater mean summer temperature than was here afforded. Pasture-grass was the crop which could be grown with the greatest success. In concluding, the President referred in terms of high praise to the work which had been done for many years past on the experimental farms at Rothamsted, observing that the only thing wanted there was the establishment of a thoroughly equipped meteorological station.

ULSTER HORTICULTURAL.

JANUARY 13.—The Lord Mayor presided at the annual general meeting of the Ulster Horticultural Society, the efficient organisation under whose auspices the "Chrysanthemum show," as it is called, has rapidly grown to be a Belfast institution.

The hon. secretary had the gratifying report to submit that, in spite of the severe weather, last year's show was better attended at all times of both days than on any previous occasion. This was to be accounted for not only by the increasing popularity of the show, but on account of the extra interest evoked by the Victoria Jubilee Championship. The receipts from all sources amounted to £659 17s. 2d., and the expenditure reached £642 14s. 2d., leaving a balance of £17 3s., which, added to the balance brought forward shows a total of £72 1s. 5d., out of which the committee unanimously resolved to devote £30 to the Royal Victoria Hospital.

CHISWICK GARDENERS' MUTUAL IMPROVEMENT.

JANUARY 20.—The fortnightly meeting of the above Society was held in the Council Chamber at the Royal Horticultural Society's Gardens on the above date, when Mr. S. T. WRIGHT gave an address, choosing as his subject "Commercial Fruit Culture."

He commenced by dealing with the subjects of soil, situation, the best varieties of fruit to plant, packing, and marketing in general. Mr. Wright touched lightly upon fruit grown under glass, taking in their order Grapes, Peaches, Nectarines, Figs, with cultural notes on each.

A lengthy discussion followed the lecturer's most excellent address.

NATIONAL CHRYSANTHEMUM.

JANUARY 24.—A meeting of the General Committee was held on the above date at Anderton's Hotel, Fleet Street, Mr. T. W. SANDERS in the chair. A letter was read from Sir E. SAUNDERS, the President of the Society, promising to give the sum of twenty pounds as a President's special first prize for twelve vases of Specimen blooms of Japanese Chrysanthemums—a communication which was received with great satisfaction. The competition in this class will take place at the November show, and the committee have added other prizes of £15, £10, and £5.

The Secretary brought up a report from the Rules Revision Sub-committee, who had dealt thoroughly with the rules, bringing them more into harmony with the action and requirements of the Society; and they were passed with a few alterations. The Secretary submitted a rough financial statement showing that the income of the Society for the year had reached the sum of nearly one thousand pounds; with a probable accession to the income of over one hundred pounds more before the close of the financial year. It was resolved that a meeting of the Special Classification Committee should be held on the 31st inst., and the annual general meeting on February 28; also that a smoking concert was being arranged for the benefit of the Reserve Fund to take place at Anderton's Hotel, on February 14. Three candidates for membership were elected, and the Dalkey (Ireland), and the Lowestoft Chrysanthemum Societies were admitted to affiliation. The usual vote of thanks was passed to the chairman for presiding.

CATALOGUES RECEIVED

HOOPER & Co., Central Avenue, Covent Garden, London, W.C.—Seeds.
FRED. SMITH & Co., Church Street, Woodbridge, Suffolk—Seeds, &c.

The districts indicated by number in the first column are the following:—

0, Scotland, N. *Principal Wheat-producing Districts*—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. *Principal Grazing, &c., Districts*—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

THE following summary record of the weather throughout the British Islands for the week ending January 22, is furnished from the Meteorological Office:—

"The weather during this period was again unsettled in the extreme north and north-west, where frequent rains occurred, but elsewhere, although slight rain was experienced at times, it was mainly dry, with, however, a good deal of fog or mist. On the night of Friday considerable quantities of wet snow and cold rain fell in the north and east of Scotland.

"The temperature was much above the mean, the excess varying from 5° in 'Scotland, N.' to 7° or 8° in all other districts. The absolute maxima were very high for the time of year, especially in the extreme north, and were recorded during the middle of the week. They varied from 60° in 'Scotland, N.' (at Wick), and 59° in 'Scotland, E.' and the 'Midland Counties,' to 55° in 'England, E., S., S.W., and N.W.' The lowest of the minima were registered during the earlier part of the week, and varied from 25° in 'Scotland, E.' and 26° in 'England, S.W.' to 32° in 'Scotland, W.,' 34° in 'Ireland, N.,' and 37° in 'Ireland, S.,' and the 'Channel Islands.'

"The Rainfall was generally in excess of the mean in 'Scotland, N.,' and just equal to it in 'Scotland, E.,' but in all other districts there was a deficit. Over the eastern, central, and southern parts of England and the Channel Islands the fall was extremely slight.

"The Bright Sunshine was considerably less than the mean in all districts excepting the Channel Islands, where there was a large excess. The percentage of the possible duration ranged from 30 in the Channel Islands, 12 in 'England, S.' and 'Ireland, S.,' and 11 in 'England, S.W.,' to 5 in 'Scotland, N.,' and to 2 in 'England, E.' "

NOTICES TO CORRESPONDENTS.

ADVANTAGE OF SHALLOW FRAMES: *W. T.* Before bees can commence work in supers, the temperature must be raised therein to about that prevailing in the brood-chamber; if, therefore, we give a big skep or a set of standard-sized frames, the bees may be unable to produce the desired temperature, in which case they remain crowded below, and swarm in due course. If instead of a big, and possibly badly-protected super, we give to skeps one of 6 inches in depth, or to movable comb-hives a set of shallow frames, and cover them well, the desired warmth is more likely to be quickly raised; and then the bees would undoubtedly enter with the object of building comb and storing honey. Then, again, shallow supers when full are not cumbersome to move about, or raise when putting the super-clearer in position; and, lastly, the greatest advantage of all, in my opinion, comes when the work of extracting commences, for the cappings are not only easily removed, but the honey is thrown out with less liability to damage the combs. *Expert.*

"ARUM LILIES MANURE:" *A. Reader.* Put into a 40-gallon cask or cistern 2 bushels of fresh horse-dung, stir it well about, and leave it to clear; and in about a week add 1 peck of fresh soot enclosed in a canvas bag, squeezing this a little every third day, so as to make its contents exude. Let the mixture get clear, and then use, say, 1 quart to 3 gallons of rain or soft water. This is a good manure for all kinds of soft-wooded plants. It may be made stronger for applying to Cannas, Brugmansias, and coarse-growing plants generally, by adding chicken's or pigeon's dung, at the rate of half a peck to the above quantities. If in summer-time bubbles generate on the surface, it is a symptom of fermentation, and the latter should be stayed by the addition of a small quantity of white vitriol. Of course, after the cask has been filled up twice, the contents should be turned out and a fresh lot made up. Instead of clear water, soap-suds may be used in filling up the cask. If an artificial manure is preferred, you should consult our advertising columns.

BEGONIAS GLOIRE DE LORRAINE AND GLOIRE DE SCEAUX: *Amateur.* When the flowering is past, afford the plants a few weeks' rest by keeping them moderately dry. Cut off the stems to within three or four joints (nodes) from the base, and gradually increase the moisture till the young growths from the nodes are fairly developed, then repot in a compost of loam, leaf-mould, and sand. Cuttings should be taken from the new growths only, and placed in a warm case. When these have rooted and been potted off, the temperature of a warm greenhouse is sufficient, or they should be placed in the warmest part of an ordinary greenhouse. These Begonias do not thrive out-of-doors here, but do well on the continent. *J. V. & Sons.*

BOOKS: *Enquirer.* Donald's *Dictionary of Gardening*, containing all the modern improvements, &c., was published in 1807. It is a quarto, in two volumes, with twenty-four plates. It is not in the Lindley Library. We do not know the value, but should assess it low.—*T. R.* *Cucumber Culture for Amateurs*, by W. G. May; *The Tomato: Its Culture and Uses*, by W. Iggulden; both obtainable at the Bazaar office, 171, Strand, W.C. We know of no manual on the cultivation of Aspidistra, and no gardener of even moderate experience should need one.—*A. M. D.* *Scott's Structural Botany*, 2 vols. (A. & C. Black); *F. Darwin's Elements of Botany* (Clay); *Hardy Ornamental Flowering Trees and Shrubs*, by A. D. Webster, published at the Gardening World Office, 1, Clement's Inn, W.C.

BRONZE OR METAL STATUES: "*A. G.*" may possibly obtain these of Messrs. Singer & Sons, Frome, Somerset, who are workers in all this class of goods. *H. J. W.*

CLUBBING: *A. G. B.* Afford the land complete rest for two or three years from every kind of crop of the Brassica order, and afford it a dressing or two of gas-lime; and you will, by that means, starve out the slime fungus that is the cause of clubbing.

CONTINUOUS COVERED-WAY ESPALIERS: *H. H. R.* In theory, perhaps, you ought to be right, but in practice there is no reason why fruit-trees grown on arches should not produce as fine fruits, and in as great abundance, as free-standing espaliers, provided the trees have proper attention at root and top. Of course, only such varieties of Pears

and Plums should be grown as do not require the warmth afforded by a wall.

CORRECTION.—The Kniphofia described under "Kew Notes" last week is *K. primulina*.

CUCUMBERS ON NEW YEAR'S DAY: *X.* The first record we find is one to the effect that Mr. Fowler, gardener to Sir N. Gould at Stoke Newington, was the first to raise Cucumbers in autumn for fruiting about Christmas. He presented King George I. with a brace of full-grown ones on New Year's Day, 1721. See Johnson's *History of English Gardening* (1829), p. 153.

INDUCING EARLY SWARMS: *W. T.* Take the supers off the skeps if they are still on, and examine the combs of the stocks by inverting the hives and driving the bees down with smoke to see how the supply of food is lasting, as the weight of the hive now is not a reliable test when the combs contain so much brood and generally so little honey. Scrape the floor-boards, and then, having made the hives snug and clean, place over the feed-hole either a three or four-pound cake of soft candy, or give a pint of warm syrup once a week, until the flowers begin to bloom in quantity, but be sure not to give too much syrup, or you will retard instead of accelerate swarming. The candy would probably be ample, but to make sure give a pint of warm syrup at once, and then the cake of candy, with warm wraps in the shape of bags or pieces of carpet under the milk-pan. Leave the hive thus, and await the issue of swarms, which you may expect about the middle of May. *Expert.*

MINERAL INGREDIENTS OF SOILS: *B. G. S.* These vary very considerably. An ideal soil for farm purposes would consist of sand, 50 to 70 per cent.; clay, 20 to 30 per cent.; pulverised limestone, 5 to 10 per cent.; and humus, 5 to 10 per cent. Soils vary according to their origin, and the rocks of which they form the disintegrated remains; and silica, lime, alumina, iron, magnesia, and potash form the chemical composition of most of them, these substances being found in various proportions, in accordance with the basis of the soil.

NAMES OF FRUITS: *H. H.* 1, Cox's Pomona; 2, not known.—*Pear.* Black Worcester or Achan.—*E. S.* *Physalis Alkekengi*.—*B. G.* *Pear Winter Nelis*.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*C. P.* *Arbroath*. 4, *Grevillea alpina*, var.—*C. A. G.* *Dendrobium æmulum*, a native of New South Wales. *C. P.* 1, *Polypodium peltideum* (phymatodes); 2, *Adiantum Cunninghami*; 3, *Doodia media*; 4, appears to be *Pteris esculenta*, an ally of our common Bracken, but we fail to find spores on the withered specimens received; 5, *Adiantum capillus-veneris*; 6, *Lastrea decomposita*; 7, *Lastrea denticulata*; 8, *Polystichum vestitum*; 9, *Davallia canariensis*; 10, *Lastrea filix-mas polydactyla*; 11, *Platylopha falcatum*; 12, *Cyrtomium falcatum*. We have given the popular names so far as we can judge, some being merely immature barren fronds.—*S. L.* It is difficult to name Conifers from their shoots only. 1, Probably the Deodar; 2, *Pseudotsuga Douglasii*; 3, *Thuja dolabrata*; 4, *Cupressus Lawsoniana*, probably the form called *erecta viridis*; 5, *Thuja japonica* alias *Standishi*; 7, *Cryptomeria japonica elegans*; 8, *Cupressus* (*Retinospora* of gardens) *pisifera squarrosa*; 9, *Cupressus* (*Retinospora*) *plumosa*.—*H. H.* *Sedum carneum variegatum*.—*Alt. Lyddiard.* *Lonicera fragrantissima*.—*G. R. B.* 1, *Maranta picta*; 2, *Peperomia ariifolia*; 3, *Hibiscus Cooperi*; 4, *Begonia argyrostigma*; 5, *Glechoma hederacea variegata* (variegated Ground Ivy).—*W. H. Divers.* 1, *Cytisus proliferus*; 2, *Iris unguicularis*; 3, *Crocus ancyrensis*.—*Zest.* The Fern is *Platylopha flexuosum*; the purple-leaved yellow-flowered plant, *Gynura aurantiaca* of gardens. *Fred. F. Baillache.* The silk-cotton is that of *Ochroma lagopus*, a soft-wooded Malvaceous tree, about 40 feet high, native of the West Indies and Central America. The silk-cotton or floss is of little or no commercial value, but is sometimes used for stuffing cushions. It cannot compete with "Kapok," from *Eriodendron anfractuosum*. *J. R. J.*—*Hamming.* *Garrya elliptica*.—*H. H.* *Darmstadt.* *Gomesa planifolia*.

PETALS OF CAMELLIAS DROPPING: *A. H.* This defect occurs when a plant is carrying an excessive number of blooms, and when the soil contains too much moisture, or the air of the house is very dry, or soil and air are dry. In fact, it is occasioned by anything that checks healthy development.

POSITION OF ARAUCARIA IMBRICATA SEED IN THE SEED-POT: *R.* The seeds should be buried with pointed end downwards, the thick end protruding from the soil about a quarter of an inch.

ROYAL HORTICULTURAL SOCIETY'S EXAMINATION SUBJECTS: *B. G. S.* Apply to the Secretary, the Rev. W. Wilks, 117, Victoria Street, S.W.

SELECT PEAS FOR SUCCESSION: *J. W.* *Chelsea Gem*, or *Veitch's Earliest Marrow*, the first being 1½ feet, and the latter 4 feet high. Let the next to follow be *Gradus*, or *William I.*, both about 3 feet. *Maincrop* Peas of good quality and prolific are *Advancer*, *Champion of England*, *Duke of Albany*, *Huntingdonian*, *Prodigy*, *Veitch's Perfection*. exhibition varieties are wanted, there are *Telephone*, *Stratagem*, *Masterpiece*, and *Autocrat*. Peas for the latest sowing are *British Queen*, *Ne Plus Ultra*, *Sturdy*, and *Maclean's Best-of-All*. Peas should be sown from February to the end of June at fortnightly intervals, in flat broad drills, about 3 inches deep, and if these can be arranged in single or double rows in various parts of the garden, the produce will be greater, and the amount of land the crops occupy less than if a quarter be entirely devoted to Peas.

SPRING FLOWERS AT USK: *R. W. R.* The unusual mildness sufficiently accounts for the early flowering of the plants named.

SUITABLE PLANTS FOR BEES: *W. T.* To limit myself to one particular plant only, I should prefer *Arabis alba*. It is a valuable plant to grow for bees, blooming early in the spring, and continuing through the summer. Now is a good time to sow the seed, and when large enough, plant in permanent places 1 ft. apart each way, or sow in drills 1 ft. apart, where they are to remain and thin out, leaving each plant the above distance apart. I should advise anyone to plant more of a selection of bee-flowers, which will prove a great attraction for his bees, such as *Crocus*, *Arabis*, *Wallflower*, *Limnanthes Douglasii*. These spring-blooming plants, I think, ought to be grown by every bee-keeper, they coming in bloom when the bee forage is scarce, and the bees certainly pay these plants great attention in the spring of the year. For the autumn, nothing beats *Anchusa*, "*Chapman honey-plant*," and *Echinops Ritro*, the latter proving an ideal honey-producing plant. *Expert.*

UNITED HORTICULTURAL BENEFIT AND PROVIDENT INSTITUTION: *J. F. Hants.* The address of the Secretary of this Society has been repeatedly given in this column. However, we gladly repeat it as you have failed to notice it heretofore. It is W. Collins, 9, Martindale Road, Balham, S.W., and he will furnish you with the rules and other information you ask.

WATER BOUQUET: *W. P.* A lady correspondent, *F. B.*, kindly informs us that this kind of bouquet is "*a Dorset specialty*," and that a full description was given in *The Queen* for January 15 last (see also p. 73).

WORM-EATING SLUGS.—Correspondents from Southampton, Ealing, and elsewhere have kindly forwarded specimens.

COMMUNICATIONS RECEIVED.—*J. R.*—*C. N.*, Antibes.—*D. Guibéneuf*, Paris.—*G. H. K.*—*E. A.*, Geneva.—*J. Simpson*.—*P. T. F.*—*N. W.*, Vienna.—*W. B. H.*—*J. G.* (shortly).—*H. W. W.*—*R. P. B.*—*J. G. B.*—*R. N.*—*H. T. M.*—*H. M.*—*T. D. S.*—*H. H.*—*D. Ombrain*.—*Goodlife*, Worthing.—*E. K.*—*R. S.* & Co.—*H. D.*—*A. J. L.*—*W. S.*—*A. D.*—*H. W. W.*—*J. R. W.*

PHOTOGRAPHS, SPECIMENS, ETC., RECEIVED.—*F. M. B.*, Brisbane.—*R. V. & Sons.*—*H. Cannell* (with thanks).

DIED.—On the 24th of January, at Hollycot, Cockington, after a long and severe illness, in his 28th year, WILLIAM THOMAS (WILLIE) MORRIS, the eldest and beloved son of W. H. Morris, of the Devon Rosery, Torquay. Funeral at 2.30 P.M. on Saturday.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "*Gardeners' Chronicle*" has, since the reduction in the price of the paper,

MORE THAN DOUBLED, and that it continues to increase weekly. Advertisers are reminded that the "*Chronicle*" circulates among COUNTRY GENTLEMEN, and ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

(For Markets see p. xiv.)

THE

Gardeners' Chronicle.

SATURDAY, FEBRUARY 5, 1898.

PALMS IN THE LIVING-ROOM.

THIS manual of 128 pages,* lately published in Germany, supplies a long-felt want, and affords just the right sort of information that the layman desires who wishes to grow a few Palms in his drawing-room, living-room, window-ledge, table, or *jardinière*, and who is in great doubt as to the methods he should pursue in order to maintain his handsome and, perhaps, expensive Palms in health and beauty. The gardener by profession, if he have not had some years of experience in an extensive private garden, or in nurseries or botanical gardens, looks in vain in the ordinary manuals on the cultivation of plants.

The object the author had in view in writing was the extension of the circle of Palm fanciers in his own country; and some part of the work, particularly that applicable to the care of Palms grown in rooms heated by the close stoves in common use in Germany, is of lesser importance here; but that apart, the work embodies the results of close observation, and shows much cultural skill, as well as peculiar information and research on the part of the author. He tells us that about 1100 different forms of Palms are known, having their habitat between the tropics, a few extending beyond to the 44° of N. lat., as the *Chamaerops* in Europe, and *Nannorops* in Asia to the 34°; in *Sabal*, in North America to the 36° N. lat.; *Kentia*, in New Zealand, to the 44° S. lat.; and *Eubæa*, in Chili, to the 37° S. lat. All of these subtropical species adapt themselves to room culture requiring no great degree of warmth, a not very moist air, and some of them at certain seasons a cooler temperature. Sunlight is a necessity to all Palms, and the lighter the position the better the plants thrive; therefore, the vicinity of a window is the best place for them. This position is, however, a dangerous one in the winter, when cold draughts penetrate the best-made windows, chilling the roots, the tenderest and most susceptible part of the plants. Methods, however, are indicated, by which this evil may in great measure be averted, and these are extremely simple. An even, regular temperature is very essential to success, and one good method of retaining the more tender species in health, is to cover them at night with a piece of wetted gauze, but not so that it comes into contact with the plant. Of course, that is described as being merely a makeshift, a glass-case being preferable. Other means are indicated for maintaining the roots in an equable medium by dropping the pot into a larger one, and filling the intervening space with soil or sawdust, or by enclosing the pots,

if small ones, in wooden or other cases, and filling in between with sawdust or earth, and, in the case of earth being used, planting therein *Selaginella* or *Nertera depressa*.

Of great importance is the wintering of Palms—and it is the more remarkable that the hardier the species the greater the difficulty, these needing in the winter a resting period, but which in the dwelling can only be afforded by a low temperature, and a frost-proof, well-lighted, unheated room, is rarely to be found in any house. And in ventilating a room during times of hard frost, the Palms must be removed, or covered with cloths. Moreover, the roots of these species are more liable to injury from a degree or two of frost than the leaves, and the pots should always be surrounded in the cold season with some non-conducting material, as felt, wood-wool, woollen-cloth, or wadding.

The warmer species need much less care, and these in the winter are quite at home in the living-room, and, if possible, near the window, protected against draughts, either hot or cold.

We are told the best season at which to buy our Palms, namely, late summer, when they are well established and the growth mature; and, above all things, to be shy of buying them from out of the florists' windows, where but little care is given them, and which may have the seeds of early death in them, though as yet invisible.

Much excellent matter is found on the rearing in apartments of diverse species of Palms from seed, and the varied manner in which the seed germinates. In the case of the Date-Palm and many others, after a shorter or longer time, on a certain part of the seed a minute white point appears, and grows to a considerable length downwards, whilst the fore-end swells somewhat. After this point has reached a certain length, a minute slit appears near its end, and out of this a new point appears, which takes an upward direction. Concurrently the first point gets longer and thinner and further downwards. When the upward-growing point has reached a length of 1 cent. it opens, and another point is extruded, which is somewhat larger, 2 to 3 cm. long, and from this shoot the first long and thin green leaf appears; meanwhile, from the swollen point of union, several roots have been emitted, and taken a downward direction. In *Areca*, *Acrocomia*, and *Sabal*, the downward striking point goes sideways into the earth, so that the base, as in *Phoenix*, &c., is equally deep in the earth. The various methods of germination offer numerous hints of value, and throw much light on the kind of cultivation needed by the plants, which our author does not fail to elaborate.

In the chapter on the Cultivation of Palms, good and faulty methods are contrasted, and reasons given, especial attention being directed to the so-called true and the false stilt-like roots of some species, and the treatment indicated for avoiding this evil when it is not inherent in the plant. The treatment of coiled roots, often found at the bottom of the pots and tubs, is, we believe, managed entirely empirically by English gardeners, who try to uncoil them, thus breaking them, and bringing the plant into a bad state of health from which there is no recovery, excepting strong bottom-heat be employed for several months afterwards. The roots of most species of Palms may be pruned back with a sharp knife if the plants be thus treated.

There is a capital chapter on soils, on the

croaking of pots and tubs—a most important matter. The forms of pot suitable to the growth of various species, choosing deep pots for those having stilt-like and long tap roots, and broad, shallow ones for surface-rooters. Potting receives full attention, and we are told that Palms must not have large shifts at a time, or be loosely potted; and that the surface of the soil should slope from the side to the centre, in order that the soil should not remain dry in the middle of the ball, and hinder the formation of new roots.

When should a Palm be afforded water? is with gardeners and amateurs an all-important query; and so far we have never seemed to have the right answer, because these have been mainly guesses at the reasons that should govern the application. The author says that the turgidity of the leaves and stem, which can readily be ascertained by the inability of the tips to be bent easily round the finger. If a plant be dry, the tips can be coiled round the finger with ease. The whole matter is made clear to the least botanically-instructed reader by a description of the construction of the stem and the leaves. A little wilting does no harm. Warm water should always be used for Palms kept in rooms and hothouses, as warm indeed as 68° Fahr.

A chapter is devoted to the manuring of Palms, and an analysis given of the ash of the *Livistonia chinensis*, from the work of Comte Kerchove de Denterghem; and another chapter is concerned with Palms in ill-health.

Rather more than half the book consists of brief descriptions of the more important genera of Palms and their varieties, a particularly useful section, not available in any but the more expensive works of Kerchove, Drude, and others. It is to be hoped that this book will be translated into English, as we have nothing but Seemann's book, now out of print; and the papers by Mr. W. Watson, scattered through more than one volume of the *Gardeners' Chronicle*.

NEW OR NOTEWORTHY PLANTS.

SOPHRONITIS GRANDIFLORA
"SWINBURNE'S VARIETY."

THIS is a remarkable variety in every respect, and especially in the thick substance of its flowers and leaves, and in the extraordinary breadth of the sepals and petals, the latter being as nearly circular as possible.

There are two well-defined classes of *Sophronitis grandiflora*, the one with the comparatively long and narrow pseudo-bulbs and upright leaves; and the other with short pseudo-bulbs and broad, less ascending foliage. By the leaf sent with the flower, this would belong to the latter class, for it is broadly ovate, and nearly a quarter of an inch thick.

There is nothing abnormal about the flower sent, and yet at a cursory glance it might easily be taken for a scarlet tuberous *Begonia*. It measures nearly three inches across the petals, each of which are exactly one and a half inches broad. The petals are also much broader than in ordinary forms, and the lip larger and more conspicuous by reason of its clearly-defined scarlet lines on an orange-coloured ground. The sepals and petals are light scarlet, with a slight shade of carmine towards the edges, and in the veining which extends over their surface. It came in an importation made by Messrs. W. L. Lewis & Co., two years ago, and flowered with T. W. Swinburne, Esq., Corndean Hall, Winchcombe, who was so surprised by its peculiar flower that he remarked in his letter that it seemed to have been crossed with something else. James O'Brien.

* *Palmenzucht und Palmenpflege*, by Dr. Udo Dammer, Kustos des Königlichen Botanischen Gartens zu Berlin. Twenty-four illustrations. (Trowitzsch & Son, Frankfurt-on-Main.) *The Propagation and Cultivation of Palms*.

ORCHID NOTES AND GLEANINGS.

VANDA TERES AT GUNNERSBURY PARK.

THESE plants have for so long a time been a theme of interest, and to many of astonishment, that it was but natural, being in the immediate neighbourhood a few days ago, that I should make a special effort to visit the place and see for myself how the plants were managed; and note the condition they were in, and what were the prospects for coming flower. Well, after careful inspection, I must confess I was more than satisfied; the condition of the plants was much better than anything I had anticipated. I remember visiting these gardens in Mr. Roberts' time, and then noting the general excellence of everything that came under my observation. I also remember that then this Vanda was passing through the experimental stages of special culture. It is experimental no longer, but the method then adopted has been continued ever since, so that now as far as my observation goes, the finest lot of Vanda teres is now to be met with at Gunnersbury Park. What there may be in other establishments near Tring I cannot say, as I have not visited them, but if they come in any way up to these now mentioned they must be fine indeed.

It would seem, judging by the stout growth and terete leaves, as well as by the large quantity of healthy roots, that this box-culture close to the end of a warm house where light and sun-heat can be secured, is just the place for them; placed as the plants are in crocks, charcoal, and moss, pressed only moderately firmly together, they can be, and are in the growing season freely syringed, but this latter operation is discontinued during the winter months. In the spring the numerous spikes push out, and in due time the glorious flowers will open, when such a sight will be presented as can scarcely be met with anywhere.

I congratulate Mr. Reynolds on his successful method of growing this plant, on the excellent condition in which I found everything about the place (fog taken into consideration), and beg to thank him for his kindness in conducting me through the whole of the glass-houses, and various parts of this beautiful park. Many things were worthy of special note, but a little later when growth is pushing and new foliage and flowers appear, a more satisfactory note may be made than early in January. *W. Swan, Bystock, Exmouth.*

CATTLEYA CANDIDA (*Lehm.*).

In giving this name to the species originally imported and distributed as *C. chocoensis*, Consul F. C. Lehmann gives us a reasonable cause for the change (*Gard. Chron.*, Oct. 26, 1896, p. 486): "This Cattleya does not grow in the Choco, but in the Cauca Valley, two quite different provinces;" and adds the following interesting particulars. "Cattleya candida is distributed over the Valley of the Cauca from Tulna down to the neighbourhood of Fredonia and Concordia in Antioquia, and is restricted to a region which extends from 600 to 1,100 metres above the sea-level. The climate of this region is very damp for some six months in the year, and very dry during three months in the time at which the plant flowers."

A beautiful example of it is sent by Joseph Broome, Esq., Sunny Hill, Llandudno, whose Cattleyas invariably develop flowers of fine quality, their excellence being probably in a great measure due to the genial air of the place. The sepals and petals are white, the latter very broad and crimped after the manner peculiar to the species. The lip is also white, with a faint purple glow in the tube, at the base of which are some dark rose lines merging into orange, the front tube being of a rich velvety ruby-red changing to violet, the whole having a broad, pure white, crimped margin. It is one of the most beautiful of the labiata section, and so variable that it is difficult to get two plants exactly alike. The flowers also are fragrant.

ONCIDIUM UNGUICULATUM.

Although the individual flowers of this species are not so showy as those of *O. tigrinum* of which some

authorities make it a variety, its habit of profuse flowering and the long duration of the blooms, make it of much decorative value, especially at the present season. A good example of it is sent by R. W. Rickards, Esq., The Priory, Usk, Monmouthshire. The sepals and petals are heavily barred with dark brown, and the lip, which differs from that of *O. tigrinum* in having the bright yellow-coloured front lobe on a long and narrow isthmus. The plant makes good growth, and flowers satisfactorily in an intermediate temperature. *J. O'B.*

KEW NOTES.

TREES AND SHRUBS IN FLOWER DURING LATE JANUARY.—The exceptional mildness of the winter is bringing many things into flower considerably in advance of their usual time. Whilst this makes the garden brighter than it otherwise would be in late January and early February, it has its disadvantages in hastening unduly the growth of many trees and shrubs, for which an English spring is, in any case, a perilous time. But like his *confrère* in agriculture, the gardener is difficult to please in regard to weather. To the owner of an extensive collection of foreign trees and shrubs, a mild winter is, after all, the greatest boon. His tenderer plants can start where they left off the previous autumn, and that means a great deal with such things as *Cæsalpinia japonica*, *Azalea* (more properly *Rhododendron*) *rhombica*, and many others of the same stamp, which, once they get hard and woody, are perfectly secure against frost, but which, in a small state, are apt to be cut back time after time almost to where they started the previous spring. Such things as those mentioned in the following notes, however, do not belong to that category; whatever risks their flowers may have to encounter, the plants themselves are proof against any English winter. How much our gardens owe to comparatively recent introductions is shown in even so short a list as that of January-flowering shrubs and trees. It is not so very long ago that no mention could have been made of the *Hamamelis* or *Prunus Davidiana*, which to-day occupy quite a prominent place. *W. J. B.*

HARDY PLANTS.

As evidence of the exceptional mildness of the weather experienced during the month of January, the following list of hardy plants now in flower in the open air, chiefly in the Rock Garden, at Kew, may be interesting:—*Anemone angulosa*, *A. blanda*, *A. hepatica*, *Callianthemum anemonoides*, *Colchicum montanum*, *Corydalis rutefolia*, *Crocus biflorus*, *C. chrysanthus*, *C. Crewii*, *C. dalmaticus*, *C. etruscus*, *C. garganicus*, *C. Imperati*, *C. Korolkowi*, *C. Oliveri*, *C. reticulatus*, *C. Sieberi*, *C. Suterianus*, *Cyclamen europæum*, *Eranthis hyemalis*, *Galanthus Alleni*, *G. Elwesii*, *G. Icaria*, *G. nivalis*, *Helleborus antiquorum*, *H. caucasicus*, *H. colchicus*, *H. cyclophyllus*, *H. viridis*, *Hacquetia epipactis*, *Iris biflora*, *I. persica*, *I. reticulata*, *I. Suwarowi*, *I. unguiculata (stylosa)*, *Leucojum vernalis*, *Merendera caucasica*, *Morisia hypogæa*, *Mandragora autumnalis*, *Narcissus minor*, *N. minimus*, *Ornithogalum montanum*, *Petasites albus*, *P. niveus*, *P. fragrans*, *P. spurius*, *Primula acaulis*, *P. a. cœrulea*, *P. denticulata*, *Scilla bifolia*, *S. sibirica*, *Saxifraga ligulata*, *Sternbergia Fischeriana*. *W. W.*

THE WITCH-HAZELS.

Hamamelis arborea (see *Gardeners' Chronicle*, Feb. 7, 1874, fig. 47) is undoubtedly the best of the Witch-Hazels, and one of the most beautiful as well as the most interesting of our earliest-flowering trees. There is something in its appearance that strikes one as essentially Japanese. Is it because its miniature-tree-like habit, its crooked branches, and curious flowers (made up, as it were, of little strips of twisted gold leaf) suggest the fanciful efforts of the Japanese artist "on many a screen and fan?" *H. japonica* is not so good a plant; it does not flower so freely, nor are its blossoms of so rich a colour. The new variety, *Zuccariniana*, is more promising, the pale lemon-yellow of its flowers rendering it very

distinct. All these Witch-Hazels, being without leaf at flowering time, should, if possible, be associated with dark-leaved evergreens, like Holly.

RHODODENDROM DAURICUM.

Compared with the *Rhododendrons* that flower four months later, this is only a very modest plant, but producing, as it does, its bright, rosy-purple flowers in January and February, it has a great charm. It is represented by two forms, one deciduous, and the other more or less evergreen. Both have flat, saucer-shaped flowers, about 1½ inch across, borne usually not more than two or three together. It is a native of Siberia, and has been described as "empurple the mountain sides" when in flower.

RHODODENDRON ALTAICERENSE.

To cross a Himalayan plant (*R. arboreum*) with a North American one (*R. catawbiense*) specially forced into flower for the purpose, and thereby to add to hardy shrubs one that flowers almost as soon as mid-winter is past, was no mean achievement seventy years ago. Such was the origin of this *Rhododendron*, raised at Highclere in 1826. A group of it in The Dell at Kew has several trusses open, and many others bursting. The trusses are of medium size, and the flowers are rosy-crimson. I have never been able to satisfactorily distinguish between this and *R. Nobleanum*, raised in Waterer's nursery at Knap Hill in 1832 from *R. arboreum*, crossed with *R. caucasicum*, although it is said to have darker flowers.

LONICERA FRAGRANTISSIMA AND L. STANDISHII.

Of the two winter-flowering Honeysuckles, *L. fragrantissima* is preferable. Both have white flowers, very freely produced and charmingly fragrant, but *L. fragrantissima* has the advantage of retaining most of its leaves. This season, in fact, it is almost purely evergreen. Its leaves differ from those of *L. Standishii* in being much less pubescent, and in being rhomboidal rather than ovate, as in *L. Standishii*. The latter flowers the earlier, and we had it in bloom at the beginning of November; but both are now at their best. Both are introductions of Robert Fortune, and well worth cultivating, but *L. fragrantissima* more especially.

PRUNUS DAVIDIANA.

Of the Peaches and Almonds this is the first to flower, and in a season so favourable as the present it is in bloom early in January. It is said by the Abbé David (by whom it was first sent to Europe over thirty years ago) to be common in the outskirts of Peking, and to be one of the most conspicuous trees there. Yet it has not been many years in general cultivation. It is a very beautiful tree if planted where it has a dark background, for its flowers are pure white, and very freely borne. The variety called *rubra*, whose flowers are tinged with pale rose, does not appear to bloom so well as the other.

ERICA MEDITERRANEA HYBRIDA,

noted in these pages a few weeks ago, is still bright with its spikes of rosy flowers, and judging by previous years will remain so for as a couple of months at least. It is now joined by *Erica carnea*—perhaps one of its parents—and the most charming of dwarf Heaths.

THE CORNELIAN CHERRY (*CORNUS MAS*),

although not fully out, is already becoming conspicuous with its yellow, bursting flower-buds. It is to February, however, rather than to January that it belongs.

CLEMATIS CALYCINA (OR C. BALEARICA)

is in flower. It is evergreen, and its blossoms are creamy-white, irregularly spotted with reddish-purple. It is very pretty at this season, but cannot be included among the above as being quite hardy. It should have a wall or a sheltered corner. The same applies to *Garrya elliptica*, the male plant of which is very graceful now where it thrives well, with its long pendent catkins often 1 foot in length. *W. J. B.*

WITHANIA ORIGANIFOLIA = SALPICHROA RHOMBOIDEUM.

have received several inquiries as to the merits of a plant which has been called *Withania origanifolia*, which is offered by continental nurserymen under names of "Eufs de Coq" (Cocks'-eggs), and "La uet de Pampas." An account of it is given in *Potager d'un Curieux*, Paillex and Bois, 1885, p. 95, from which we learn that it is not a *Withania* or *Salpichroa*, and that it is a native of Buenos Aires, Montevideo, and Brazil. It was shown in

be sour, but palatable, especially when cooked and made into jam or jelly.

Plants of it are in cultivation at Kew, and I have seen it in several other collections around London.

COLEUS THYRSOIDEUS, Baker.

This is a new and handsome species of *Coleus* which was found in British Central Africa by Mr. Whyte, from whose specimens a few seeds were obtained, and from these plants have been raised at Kew which are now in flower. In habit, the plant is

ANOIGANTHUS BREVIFLORUS.

Although introduced into cultivation ten years ago, and figured in the *Gardeners' Chronicle* in 1889, and in the *Botanical Magazine*, t. 7072, this really handsome and easily-grown bulbous plant from the Cape is scarcely known outside botanical collections. It has flowered every year, in December to January at Kew since its introduction, and a good example may be seen now in the Cape-house. The bulbs and leaves are not unlike those of the *Belladonna Lily*; the scape is 15 inches high, stout, cylindrical, hollow, and it bears an umbel of from six to twelve flowers, which are tubular, $1\frac{1}{2}$ inch long, and coloured bright yellow. Offsets are freely formed at the base of the old bulbs, and these flower when two or three years old. A 6-inch pot, containing five or six bulbs, potted in loam, and kept moist, except for a few weeks after the leaves fade, gives no trouble, and will produce flowers annually which are really valuable for the conservatory in mid-winter. The genus is monotypic, and is pretty widely distributed over South Africa.

HYMENOPHYLLUM RUFESCENS.

A fine mass of this filmy Fern is the most recent addition to the Kew collection of filmies, which is now exceptionally rich both as regards the number of species and their condition generally, the house built specially for them five years ago being evidently suited to their requirements. *H. rufescens* was first found and described by Kirk, in 1878, in the *Transactions of the New Zealand Institute*. According to Mr. Baker, it is nearest *H. subtilissimum* (*æuginosum*). The fronds are triangular, about 2 inches long, the segments rather wide and flat, and the whole frond is covered with a cob-web-like pubescence. Other rare species received at the same time from New Zealand are *H. Malingii*, in the way of the western *H. sericeum*, but with more rigid, thicker fronds. It is said to grow on the old trunks of *Libocedrus Doniana*, in Hawks' Bay district. *H. montanum*, a small crisped form of the widely distributed and very variable *H. javanicum*, and *Trichomanes Colensoi*. There are forty species of *Hymenophyllum*, and thirty-five of *Trichomanes* in the Kew collection now. W. W.

GALANTHUS CILICICUS.

MR. SIEHE, of Mersina, writes about this new *Galanthus* as follows: In 1895 I found, in the Cilician Taurus, about 560 metres above the sea-level, a Snowdrop in the first days of March; almost all flowers were over and already fructifying. Mr. J. G. Baker, at Kew, determined it as a new species, *Galanthus cilicicus* (see *Gardeners' Chronicle*, 1897, i., p. 214). To ascertain the full flowering season I paid a visit to the locality on December 10, and found amongst the rocks a great many in full flower, but also many that were over. The flowers of the wild plants have the outer petals more than 3 cm. long, and more than 1 cm. broad. The flowers have a diameter of more than 6 cm. [A photo (fig. 29), in natural size, which Mr. Siehe sent to me shows flowers, the outer petals of which are 3.7 cm. long and 1.6 cm. broad, the inner petals 1.6 cm. long, 1.1 cm. broad. U. D.] Mr. Siehe says that the best way to have this plant in full flower at the beginning of November, is to place the bulbs closely together in a pot at the beginning of September. The later the bulbs are potted, the fewer are the flowers. The pots are brought into a cold lazy bed and lightly covered with earth. In the middle of October, when the bulbs are well rooted, the earth over the pots is taken away and frame-lights are laid over the bed, and slightly raised on sunny days. On the first days of November the pots are brought into a greenhouse or temperate-house to a sunny place, where they must have much fresh air and plenty of moisture. Certainly in the southern parts of England this *Galanthus* would flower in the open air as early as November. Mr. Siehe cultivates in his *hortus orientalis* at Mersina about 50,000 plants of it, which he will put into commerce this spring. Dr. Dammer, Gross Lichterfelde, Berlin.

FIG. 29.—*GALANTHUS CILICICUS* (NATIVE SPECIMEN).

it at Paris in 1877, and also a sample of jam made from the fruits.

The plant is described as a herbaceous perennial, with numerous creeping or scandent stems, small yellow-green ovate leaves, and small white axillary flowers. The fruits are oblong or egg-shaped, about 1 inch long, white when ripe, with a pine-apple-like fragrance; they have been likened to swallow's eggs.

In Paris it grew best when planted against a south wall, on which it was trained, and in the autumn was covered with fruits. These are said to

like an ordinary *Coleus*; the leaves have petioles 2 inches long, and a triangular, green coarsely toothed blade $2\frac{1}{2}$ inches wide. The thyrsoid spike of flowers is terminal, erect, 9 inches long by 2 inches in width at the base, and the flowers are numerous, $\frac{1}{2}$ inch long and coloured rich Gentian blue. Mr. Whyte found the plant on the Nyika Plateau at 6000 to 7000 ft. elevation, and he described it as "a very showy blue labiate, growing in damp situations." It is likely to prove a useful plant for the herbaceous border outside, and it may be also useful for the greenhouse in winter.

MARKET GARDENING.

WIRE TRELLIS.

THOSE trellises upon which to train the shoots on branches of Vines and Peaches, the bine of Melons and Cucumbers to, are easily and cheaply made; but we shall refer to this subject in due course, and proceed in our next contribution to make a few remarks on work of a more pressing nature.

RAISING STOCK TO BE AFTERWARDS PLANTED IN GLASS-HOUSES NOW BEING ERECTED.

It is very important that the raising of Vines, Tomatos, Melons, and Cucumbers, for planting in houses now in course of erection should be proceeded with forthwith, in order to secure some crops as early in the season as possible. The necessary number of *Vine-eyes* of Gros Maroc, Muscat of Alexandria, Black Hamburgh, Black Alicante, and Gros Colmar should be inserted either singly in 3-inch pots or from nine to eighteen in 6-inch pots and pans properly crocked, and filled to the rims with sandy loam, surfaced with sand, and covered with fine soil to the thickness of about half-an-inch, and then plunged to the rims pretty close to the glass in a hotbed, assuming that there are not yet any heated houses or pits at command. The frames should be kept close, and the heat maintained by adding some fresh fermenting material round and up to the top of the frame every week or two, and covering the glass at night with mats or other material. The Vines will soon push into growth, and should be potted-off into large 60-sized pots as soon as they have made two or three leaves, using the same description of soil as before, and which should be warmed a little previously. Return the plants to the hotbed, water them and keep close as before, and subsequently shift them into larger pots, and afford more head room as occasion requires.

Melons and Cucumbers may be raised by the same means: potting one seed in each 3-inch pot half-filled with light rich soil, a little fibry soil being placed in each pot for drainage, top-dressing the plants as soon as they have made a couple of inches of growth. Earl's Favourite, Blenheim Orange, and Lockinge Hero, are three excellent varieties to grow, being of fine flavour, handsome in appearance, and attaining to good size under ordinary cultivation.

Tomato Seed may be sown thinly in shallow boxes, having some rough pieces of turfy loam placed over the holes in the bottom for drainage. Fill them nearly to the top with light rich mould, covering the seed lightly, and press seed and soil gently together with a piece of board. As good Tomato-seed comes up very quickly, care must be exercised to remove the box or boxes to a position pretty close to the glass, and where a night temperature of from 55° to 60° is maintained, so as to promote a sturdy growth in the plants from the beginning. With this end in view, pot-off the seedlings singly into 3-inch pots before they become crowded in the boxes, using a compost consisting of about four parts good sandy loam—or failing this the best available—and one of short manure; the whole being passed through a $\frac{1}{2}$ -inch mesh-sieve, and warmed by the aid of a few hot-bricks or other means before being brought in contact with the roots, pressing the soil gently about the latter in potting. Return the plants to the hot-bed, placing the pots on sifted coal-ashes near to the glass. Afford tepid water to settle the soil, keep the atmosphere close, and shade from sunshine for a few days until the roots have taken to the soil, when the shading must be dispensed with, and sufficient air admitted to insure a sturdy growth in the plants. As in the case of Vines, Melons, and Cucumbers, the number of plants to be raised must be determined according to the amount of space there will be for cultivating them. In each case, but especially in that of Tomatos, the plants must be planted out before they become "pot" or "root-bound." To prevent the plants receiving such a check, it may be necessary to shift some of them into pots one size larger. Should Tomatos sustain this kind of check, or one from excessive dryness at the roots, the first cluster of flowers,

representing perhaps 1 lb. of fruit, will fail to set. One pound of fruit lost from each of a thousand plants, and estimating the value of the fruit at 6d. per lb., would mean about £25 on the wrong side. Regina, Chemin Rouge, and Challenger are good all-round Tomatos to grow. They are early, very prolific, the fruits are of good size, shape, colour, and quality. H. W. W.

FOREIGN CORRESPONDENCE.

CANNAS.

It may not be out of place to draw attention again to the beautiful large-flowering dwarf Cannas, known as "Crozy's Cannas." I am sure that when their good qualities, and the very little care which their culture necessitates, are better known, they will meet with greater favour than at present, for anyone who can grow a Dahlia can as well grow a Canna. A difficulty sometimes experienced, is to keep them safely through the winter, and this is done best by storing the clumps under the benches of greenhouses, on boards raised an inch or so from the ground, to prevent any dampness arising from the bottom. They should be placed in greenhouses having a temperature of about 50° to 55° Fahr. (8° to 10° R.), and where little watering is done, so as not to suffer from drip from the benches. Pelargonium-houses, &c., are very suitable. For an amateur who has no greenhouse the best place is a cellar, where frost cannot enter. It is important not to shake the earth away from the clumps after digging them up, as this helps to keep the bulbs fresh and plump until the spring, protecting them against dry or cold currents of air; they should be placed under the benches very closely, but not in such a way as to bruise the outer bulbs.

The method of cultivating Cannas has often been explained in these pages. Bear in mind that Cannas are gross feeders; they are not very particular as to soil—preferring a somewhat heavier to a light one—so long as it is nourishing and well drained. During their period of growth they require plenty of water, and a few manurial waterings will be found of service. At the same time, a Canna grown in a poorer soil, or in a pot, will stand the winter better than one grown in a heavily manured soil. The practice in Stuttgart is to dig out the bed where it is intended to plant the Canna for show, to the depth of about 1 foot or more, filling in with decayed stable-manure from hot-beds, &c., which it is intended to clear away, covering again with the soil previously dug out. This not only gives the bed a bold appearance until the Cannas have become established, but also affords good drainage. An ideal Canna should be of—(1) easy culture, and of a graceful and robust habit; (2) free-flowering, and with flowers (especially for groups) of a pure, intense colour, whilst for pot-culture delicate colours are very useful; (3), flower-spikes should be well above foliage; (4) flowers must be of such texture and durability as not to be easily injured by either rain or heat when planted in the open; (5) the spent-flowers should be self-shedding, and not cling to the stem until cleaned or shaken off.

In this particular, the useful variety Queen Charlotte fails. On the above-named lines, the hybridisation and selection of Cannas from hundreds of seedlings is annually carried on in the nursery of Mr. Wm. Pfitzer, Stuttgart, whence some of the best Canna novelties have gone out into the world. Mr. G. Ernst is also a specialist in Cannas; indeed, Stuttgart well deserves the name Canna City of Germany, given it by German gardeners, for in the summer months there are thousands of Cannas to be seen in bloom here in the public gardens and squares, and above all in the nurseries. Such fine varieties as Queen Charlotte, Reichskanzler Furst Hohenlohe, Franz Buchner, &c., coming from Stuttgart, can well compete with any of the best in existence. In my next notes I should like to say a few words about the varieties cultivated here, and of such best sorts which from personal observation I can strongly recommend. H. R. W.

HIMALAYAN RHODODENDRONS.*

(Concluded from p. 66.)

OF the forty-three species of Himalayan Rhododendrons described by Sir J. D. Hooker, I shall pass under notice only the more important; and because of its general utility in the shrubbery, and the great variety it gives, I must assign foremost rank to—

Rhododendron arboreum.—The old scarlet arboreum is to be found in many of our Cornish gardens as trees thirty feet or more in height. At Carelew, the residence of Colonel Tremayne, grow some of the finest I have ever seen, one of them being probably the first planted out of doors in Great Britain. At Tremough we have arboreum in all its varieties as high bushes twenty-five to thirty feet high, the whites, of which album and cinnamomeum are the types, being objects of exceeding beauty. Of the scores of varieties and shades scattered over our grounds, the best are those whose soft purplish-pink flowers are delicately frilled at the edges. Such gigantic trusses as we grow must be the envy of many gentlemen whose grounds are not so well adapted for Rhododendron work.

Rhododendron argenteum, a synonym of grande, is one of the early flowering of the large-leaved section. Its trusses of flowers greatly resemble those of Falconeri, but they bloom much earlier, and are therefore by some more highly prized. Growing to a height of 40 feet in favoured situations, its massive leaves covered on their under surface with a beautiful silvery tomentum, argenteum is well worth growing for the sake of the effect of its foliage on the shrubbery in winter alone.

Rhododendron Aucklandi of gardens [R. Griffithianum of Wight], is a gem of the first water, named after the late Lord Auckland, Governor-General of India. In its native habitat it is mostly found at an elevation of 9,000 feet. The individual flowers are 5 inches across, and as there are generally from seven to nine to a truss, the appearance of a tree when in full bloom is such as does not easily lend itself to a description. Some of the varieties have pure white flowers with a delicate pink tinge, others are enriched with a claret-blotch in the throat. Of the several hybrids which owe their parentage to Aucklandi, few, if any, outstrip the original for general beauty, and I should be sorry if, in our hurry to increase varieties, we lost sight altogether of the type. The finest plant to be seen in Cornwall is at Killiow, the residence of J. C. Daubuz, Esq., height 10 feet, breadth about 10 feet.

Rhododendron barbatum is another magnificent species, readily distinguished by the barbs at the base of the leaf. Its flowers are of a dazzling scarlet, arranged in a very compact, globose truss, and when seen as we grow them at Tremough, adorning plants 20 and more feet high, the grandeur of oriental gardens becomes by comparison tame; and fairyland itself cannot be more dazzling than a group of these trees seen in full flower on a sunny day after a shower.

Rhododendron campylocarpum is a yellow flowering bush of from 4 to 6 feet high. Coming from altitudes ranging from 11,000 to 14,000 feet, it is perfectly hardy, and the wonder of it is that it has not commanded a greater favour. Sir J. D. Hooker considered it the most charming of all the Himalayan species.

Rhododendron campanulatum is a mauve flower, very delicately shaded in some varieties, and of sufficient distinction to be included in any collection.

Rhododendron ciliatum is a most useful species of dwarf habit, and flowering every year in abundant profusion, making it a suitable plant for the front row of the Rhododendron-bed.

Rhododendron cinnabarinum and *Roylei* are two most beautiful kinds, with drooping flowers of peculiar habit, and are among the latest to flower.

Rhododendron Dalhousiae is found at an elevation of about 6,000 feet, growing as an epiphyte on Magnolia, Oak, and Laurel trees. We have grown it at Tremough for twenty years, but its tender constitu-

* A paper read at the Devon and Exeter Gardeners' Association on Jan. 12, by Richard Gill, Tremough, Penryn, Cornwall.

causes it to suffer under our more severe winters, flowering buds being occasionally destroyed, and young shoots cut back to the old wood.

Rhododendron Edgeworthi, another epiphyte, resembles the preceding in point of hardiness. Even in Cornwall it is not a safe subject for the open, but its powerful fragrance of its showy blooms entitles it to a place in the house during winter. It would be difficult to find two handsomer subjects than these.

Rhododendron Falconeri is the giant of the Himalayas, growing to a height of 40 feet, and confined for the most part to an altitude of 10,000 feet above sea-level. Apart from its flowers, it is a most desirable

Rhododendron Thomsoni will always hold a place among the leading crimson species and varieties. In addition to its deep blood-red corolla, it stands out very distinctly from its compatriots by virtue of the lax and graceful form of its corymb of from six to eight flowers. Of the hybrids raised from it, *Shilsoni* is far and away the best. It was obtained by the late Mr. Shilson by crossing *Thomsoni* with *barbatum*, and well perpetuates the memory of one of the keenest observers and growers of Sikkim *Rhododendrons*.

R. camelliaeflorum, *candelabrum*, *eleagnoides*, *fulgens*, *glaucum*, *lanatum*, *Maddeni*, *niveum*, *triflorum*, *virgatum*, and *Whitei*, are also species of Sikkim *Rhododendrons*.

treatment after the plants are fully established cannot fail to court starved plants, which yield little or no flower. With *Rhododendron* culture, as with every other human enterprise, thoroughness is the only road to success. The operator's only maxim should be, "What is worth doing at all is worth doing well." No royal path is open to him; his only passports are care, patience, and an observant mind. No greater fallacy can be imagined, no greater blunder perpetuated, than to suppose that, once placed in position, *Rhododendrons* are capable of looking after themselves. It must be distinctly understood, and cannot be too often or too strongly emphasised, that in our gardens the majority of them are being grown under very unnatural conditions, and the manifest duty of the cultivator is to study their requirements. To woo them into obedience, to see them, as travellers have seen them in their native wilds, arrayed in magnificent splendour, he must first acquaint himself with the conditions under which they thrive there, and then, as far as is possible, become, not a slavish, but a judicious imitator of Nature.

CYCLAMEN CILICICUM.

A SPECIES which grows in vegetable soil in shady parts of the lower hills, as well as in the upper forest region of the Cilician Taurus up to 2100 metres above sea-level, and in exposed sunny situations. As the illustration (fig. 30), after a photograph taken by M. Siehe, of Mersina, of the plant as found growing in the original locality, shows, the plant is a very profuse flowerer, and it is certainly quite hardy. U. D.

DO ORCHIDS DEGENERATE?

(Concluded from p. 67.)

THAT pretty little plant, *Cœlogyne corrugata*, first introduced some thirty years ago, is, or was not so long ago, consigned to the ranks of the unmanageables. I remember a few years ago, while visiting the Orchid-house at Kew, coming upon a large clump of this plant in a pot. I was bound to believe the label, but save for that should have passed the plant by without notice, it was so out of character and so totally different to the plants I had so often seen and admired on the Neilgherry mountains. The leaves were at least three times the length of those of the wild plants, and much more luxuriant in growth. I enquired of the young man in charge, if the plant had ever flowered, the reply was, "I have known that plant for the past four years, and during that time it has shown no signs of flowering." Its appearance, to my mind, betrayed the fact that it had long been kept in a constant state of excited growth, so different from the conditions under which it is found on its native hills, where during the long dry months of rest, it receives nothing from nature but the refreshing misty vapours to keep it from "drying off."

Take another example outside the Orchid world, viz., *Impatiens Jerdoniae*, an exquisite plant when seen in a wild state. It was introduced, I believe, about the year 1852, and after all these years how rarely one sees it flowered in this country with anything like an approach to its capabilities.

It is frequently grown in pots in peat and other substances, and kept in a growing state all the year round, whereas on its native uplands it grows on the thick branches of stunted trees, and is exposed to a yearly drought, and consequent rest of from four to six months, during which the gouty stems—which have displayed and shed their glory during October—shriveled and "dry off" so completely as to make it difficult for one to imagine how Nature can revivify such shrunk and sapless things.

FIG. 30.—CYCLAMEN CILICICUM.

(About $\frac{1}{2}$ nat. size.)

rubbery plant, its noble foliage forming an agreeable contrast to other kinds of vegetation. No *Rhododendron* garden can be said to be complete which does not find liberal room for *Falconeri*; and, what is still more in its favour, it is rarely, if ever, injured by frost with us. Many gardens in Cornwall grow it to nearly 20 feet in height.

Rhododendron ecinnium, although an undoubted variety of *Falconeri*, is sufficiently distinct from it to be included in any collection.

Rhododendron Hodgsoni is another of the large-leaved species which cannot be omitted. In its native home, like *Falconeri*, it has the remarkable habit of seeking the company of *Abies* in the Himalayas.

The number of hybrids raised from the aforementioned species are legion, but in a paper purporting to deal with species only, no place can be found for them.

A CONCLUDING HINT.

No one has a right to expect his *Rhododendrons* to give satisfaction, or to pass muster with the specialist, who is not devoted heart and soul to their welfare. Whether the start is made with seed, layers, buds, or grafts, it is essential that the work be carried out systematically, and not in that half-hearted, spasmodic manner which is all too frequent. Neglect at any one of the more critical periods of the life of the plants is bound to result in ill-kempt and unlovely specimens; while a happy-go-lucky sort of

One more example of an "unmanageable," and I have done. The Neilgherry Lily, *Lilium neilgherrense*. Although the whole of the mountain ranges of southern India have been ransacked for the sake of the bulbs of this charming Lily for importation into England, yet it is acknowledged to be extremely difficult to grow and bloom for any length of time; in fact, by many it has been relegated to the list of "unmanageables." In its native habitat I have hardly ever seen it growing in any other position, save from the clefts and fissures of rocks, where leaf-mould or vegetable matter had accumulated, and where, during the growing and flowering season, water trickled. As the dry season advances, the wet mould is converted into black dust, the stem of the plant decays, and the bulb is left in its dry and dusty bed till the following spring. Do any of the growers of this bulb imitate these conditions? I may add that this plant may be added to the list of those that stand in imminent peril of total extinction.

With reference to the Orchid family, it is a grand thing to know that Nature will allow us to cull one of her crowning treasures in these plants, and bring them from the ends of the earth to our very doors for the display of their exquisite beauty and rich fragrance; but it is assuredly a sorry thought that instead of moving cautiously, and step by step, in the importation, cultivation, and preservation of this noble order, we have recklessly, wilfully, ignorantly, for the love of gain, and regardless of the ultimate fate of tens of thousands of these plants, torn them from their native homes and brought them to our markets to be sold in batches and bundles like ordinary nursery-stock, with no thought of their ultimate fate, and thus contributing in no small degree to the total extinction of many of the most lovely species. Had a more sensible and intelligent course been pursued from the beginning, there never would have, I venture to think, existed the necessity for asking the question, "Do Orchids degenerate?" J. Lowrie.

VEGETABLES.

EARLY CARROTS.

THOSE who are not provided with hot-bed frames, and many amateurs are in that condition, may still have the sweet, tender young Carrot some few weeks earlier than the roots can be obtained from ordinary sowings made on "warm borders." Let an excavation be dug out 1½ foot deep in some warm corner of the garden, reserving enough of the clean upper layer of soil for sowing the seed in, and filling the excavated space with prepared stable-manure, or the same mixed with tree-leaves made firm by a slight trampling with the feet. When the heat has risen to 65°, and it is not likely to get warmer, cover with the mould set aside for the purpose, surrounding the bed with deep boards, or banking it up with the remainder of the mould; make firm, and sow thinly broadcast the Carrot-seed, mixed with moist sand, and cover lightly with mould. Put some wooden hoops, or bend some Bean-sticks, over the bed, and over these put garden-mats. When the plants appear, remove the mats by day, when it is fine weather, and always cover up at night. The crop will be ready for use in April and May. Good varieties for this sowing are Early Scarlet Dutch Horn, the English Scarlet Horn, and the Early Scarlet French Short Horn, with almost globular roots. Care must be taken that the soil does not get very dry before water is afforded, but this is not so likely to occur as with frame culture. On the other hand, drenching rains and showers of snow, sleet, and hail, should be guarded against, and for this purpose oiled canvas or calico may be put over the mats. For sowing in the open to succeed the hot-bed produce, Early Nantes and Early Scarlet Short Horn are excellent.

CELERIAC.

Most persons like this vegetable who have partaken of it as a salad-root cooked and prepared like Beet-root, or stewed in good soup or stock; plain boiled, it is unpalatable as a vegetable dish. Those who would like to try it should include it in their seed order, although the middle of March is soon enough to sow the seeds, which should be done under a hand-glass, or in a seed-pan in a cold frame, the plants being reared hardily, and planted out in March in rich soil. It is more convenient, in order to get at the plants, and to hoe and hand-weed the soil, to plant Celeriac on the flat in beds 4 feet wide, with alleys between of 1½ to 2 feet. Each plant should stand 15 inches from its neighbour, and the plantation receive abundance of water in hot weather, falling copious rains; and to allow the air to circulate freely amongst the plants, the lowermost leaves, which are usually undersized, and of no use to the plant, and the suckers, if any, should be early removed. The roots may be taken up and stored after removing the chief part of the foliage, but reserving the heart-leaves. They keep till late in the spring if planted in damp sand or mould in a cellar or shed that has some amount of sunlight; and roots can usually be had in good condition long after blanched Celery has bolted or decayed. It may be mentioned that excessive application of either solid or liquid manure results in coarse, very large, hollow, or split tubers, and is therefore unadvisable. A root from 4 to 5 inches in diameter is large enough for all purposes.

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. WHITE Orchid Grower, Burford, Dorking.

In the Cool-house the handsome *Odontoglossum coronarium* var. *miniaturum* is producing its flower-spikes, and is a species which grows very freely when suspended to the roof on the lightest side of the house, with its foliage almost touching the glass, and abundantly watered at all seasons. In the same house plants of *Sophranitis grandiflora* produce a brilliant effect, especially when arranged with flowering plants of *Odontoglossum crispum*. This dwarf-growing species will need plenty of root-moisture until the growths are completed, taking care, when watering the plant, not to wet the flowers. *Sophranitis violacea* thrives best when grown in the coolest part of the intermediate-house. Plants of *Cymbidium Devonianum* showing for bloom must have their spikes carefully guided over the edge of the pot, as recommended for *Angraecum pellucidum*.

Calanthes.—All of the first-flowering varieties having now passed out of bloom, their short resting season should commence, at which time the plants may be put on a dry shelf in the warmest house in full sunlight, in order to mature the pseudo-bulbs perfectly. Water must not be afforded during rest. The Regnier section of *Calanthes* now begin to open their flowers. The flowers of *C. Regnierii*, *C. nivalis*, *C. Sanderiana*, *C. Williamsii*, and *C. Stevensii*, owing to their upward inclination, cannot be observed to advantage when stood upon the ordinary stage, and it is better to arrange them on the floor in one part of the house, and if plants of *Cyperus alternifolius* are used as a background, and Maidenhair Fern is intermixed, the long, arching spikes have a pretty effect. Where cut-blooms are in request, *Calanthes* are very useful plants, as the spikes last about three weeks in water if kept in a cool-room.

Mexican-house.—The plants of *Odontoglossum citrosimum* now starting into growth should not be excited too much, or they may grow too quickly, and flowering be abortive; rather keep the plants at the cooler part of the house, affording not any water at the root till the flower-spikes show themselves, when abundance of water at the root, and a moist atmosphere, should be afforded. As soon as a young flower-spike is seen pushing up in the centre of a new growth, a piece of wadding should be wrapped round it as a protection against slugs and woodlice. In this house *Laelia autumnalis*, *L. albida*, *L. Gouldiana*, *L. Marriottiana*, *L. anceps*, and its varieties, are usually cultivated; and those plants that have passed out of bloom recently should be kept on the dry side, and soon bunches of new roots will be seen to push out from the base of the last-made pseudo-bulbs. Before, however, these make any progress, sphagnum-moss should be afforded such as require any. Strong, well-rooted specimens, in sufficiently large pots, should not be disturbed unless the compost is sour

and decayed, in which case it must be carefully extracted, and the dirt washed out from amongst the roots. After a plant thus treated has become dry, let the drainage be re-arranged, and the roots be laid in fresh materials, care being taken not to disturb the roots unnecessarily, or a considerable time will elapse before they regain sufficient strength to bloom satisfactorily. Let the plants be well raised above the rim of the pot or basket, and squeeze the materials together pretty firmly. The latter may consist of fibry-peat and sphagnum-moss, and a few thick crocks. After re-potting or top-dressing, much care in affording water is needed, the roots and rhizomes being liable to decay, especially freshly imported pieces. At the first it will suffice to moisten the compost slightly with a fine-rose watering-can, wetting the bulbs or rhizomes, and to damp the stage between the pots on fine afternoons; the night temperature being kept at about 55°, and by day as high as the sun-heat will raise it, at the same time air should be admitted carefully. On the appearance of new growth, the amount of heat, ventilation, root-moisture, and aerial humidity may be increased.

Miltonia vexillaria.—Any of these plants that were not re-potted last autumn, or those requiring to be broken up, may be attended to at this season. Some growers repot the whole stock of *M. vexillaria* at this season, and, as I am told, with very good results.

Blinds or Shading.—Those on the *Odontoglossum*-houses should at once be put up, as it may happen that in a week or so the sun will be too powerful for the plants during the middle hours of the day. During mild weather the *Odontoglossum*s may be afforded plenty of air when the temperature outside stands at 50°, top and bottom ventilators being opened; but when the thermometer shows 45° out-of-doors, air should be admitted by opening the lower ventilators only, and on the opposite side to that from which the wind comes. *Odontoglossum*s being generally in full growth, and many of them sending up flower-spikes, the nearer the night temperature is kept to 50° the better it will be for the plants.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Coleus Verschaffeltii, or any other of the dark-foliage variety, known as bedding *Coleus*, should now be propagated, making first sure that no green or white aphids infest them. As soon as the cuttings are rooted and potted-off, pinch out the point of the stem, and do not afford the plants later in the year more heat than will just keep them growing steadily and sturdily.

The Rose Garden.—Many of the plants have begun to grow, and the buds of newly-planted *Roses* are very forward; it will therefore be prudent to have a quantity of bracken, long litter, and Fir-branches at hand for use in case of sharp frosts occurring, paying especial attention to the more tender Tea *Roses* that may be situated at a distance from the protective influence of buildings, walls, and tall trees.

Tuberous-rooted Begonias.—Seeds should be sown this month if the plants are intended for bedding-out in June next. The soil found very suitable for this purpose consists of three parts leaf-soil to one of loam, with a fair quantity of sharp, clean sand, the pans being very well drained, and the soil in a proper degree of moisture—that is, neither very damp nor dry. The seed, which is very small, needs great care in sowing it evenly and regularly over the surface of the mould, and in covering it lightly with very fine soil. The seed-pans should be plunged in a brisk bottom-heat, in order to hasten its germination, and much attention is needed in affording water, so as not to disturb the seeds. The seedlings as they appear should be lifted with a pointed bit of wood, and pricked out round the sides of well-drained pans, filled with the same kind of soil as that in the seed-pans, potting them singly into small 60's as they become large enough, and taking care that the drainage is sufficient, *Begonias* being much injured by a stagnant, over-wet soil. As the plants get bigger, plant them out into frames, or repot them. The soil in which the plants are to grow during the summer should be liberally dressed with well-rotted leaf-soil, and deeply dug previously to being planted.

General Work.—The mild weather has permitted alterations, ground-work, gravelling, turfing, &c., to be carried on without much interruption. If tree or shrub planting, excepting that of *Hollies*, be uncompleted, let it be finished, as far as circumstances will allow. Get all the vacant flower-beds and borders manured and dug forthwith; and proceed

th cutting the turf-edgings to walks and beds, maintaining the true lines of the same as intended by the signer.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Vines: Early-house.—The number of bunches to be left for a crop should be decided forthwith, and the thinning of the berries carried out when these are of the size of Radish-seed. Vine-ropes which have spread of foliage on either side of about 4 feet may carry one bunch of 1 lb. weight to each foot of rod, in the case of very strong Vines, a little more than this. In thinning a bunch of Grapes, the thinner should use a pair of proper Grape-scissors that are sharp towards the points, and a small piece of stick or Birch-twigg with a forked tip in the left hand, to steady the bunch while it is being operated upon; and he must take great care not to bruise or prick the berries left in the bunch, or rub them with the hand, but let them touch his hair. Early Grapes are not expected to be so large as late ones, and this fact should be borne in mind by the thinner, his aim being closeness and compactness of bunch, so that a bunch when cut and laid on a dish will retain its shape, and not fall all abroad. In order to have this desirable form, the berries should be close together without being crowded. In every case the lower part of the bunch should be taken in hand first, beginning by cutting out the smaller and unfertilised berries, always proceeding in an upward direction, and going over it a second time, and thus reduce the berries required as much as may be, at the same time leaving them as evenly distributed over the bunch as possible. The berries on the four shoulders of the bunch having nothing to crowd, should be left in larger numbers than elsewhere, taking care to leave no seedless ones. It is good practice to go over the Vines once or twice a week, and remove and stop all lateral shoots not wanted for fruit-carrying another year. The inside border, if found but slightly moist on examination, must be afforded a thorough application of tepid manure-water, or a top-dressing with artificial or other manure before affording clear warm water. If the heat in the fermenting materials covering the outside border has declined, add enough fresh well-prepared materials in a heated condition, remaking the mass throughout. The same range of temperatures as those recommended in last week's Calendar should be maintained, and see that the ventilation is carefully carried out, so that it will not render the foliage shabby and thin by too little air being admitted on favourable days, or it will be very liable to get scorched later on in the year. The amount of damping-down that is done should vary in accordance with the weather and the amount of fire-heat that is employed, once a day being enough on days that are mild and damp, and in sunny or frosty weather four times may not be too many. Be careful, if you would avoid rusted berries, not to throw water over the hot-water pipes when these are in a heated state.

Potted Vines.—When the Vines are of medium strength, six bunches are enough for a crop, but strong ones may carry eight bunches. If the Vines are afforded bottom-heat by means of dung and leaves, this should not exceed 75°. If declining, add some small quantity of fresh materials. The same kind of general treatment is required for potted Vines as for permanent Vines, except in affording water, which must be in accordance with requirements; and it may be necessary to examine the state of the soil every day, as it must never be allowed to become quite dry, nor, on the other hand, should it be kept continually moist. Manure-water may be afforded once or twice a week when the plants are in active growth, and roots have appeared on the surface of the soil.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

Tomatos.—If seeds were sown as advised, the seedlings will now require to be transferred to small pots, using mellow loam and leaf-mould in equal parts, with a small quantity of rotten manure and coarse sand, and place them in a position close up to the glass in a temperature of 60° to 65°. Shade them from the sun for a few days, and afford but a small amount of water for a week or so after potting; when the days are fine ventilate them a little in order to strengthen the growth.

Celery.—A small quantity of seed of Standard Weaver, or any white variety, may now be sown in finely-sifted rich soil, the seeds slightly covered with soil, and the pans or boxes placed in a structure

having a temperature of 50°. There is a pretty constant demand in the kitchen for unblanched Celery during early summer for flavouring purposes.

Shallots, Garlic, and Chives.—These allied members of the Onion family may now be divided and planted. In the case of the first two, let the soil be forked over, levelled, and then made firm, as for Onion sowing, and draw drills at 1 foot apart, $\frac{1}{2}$ inch deep, press the cloves slightly into the soil at the bottom of the drills at 6 inches apart, then with a hoe or small rake draw the soil up to and almost over them. Chives may be divided into small bundles and planted in rows at 1 foot apart on the flat. The plant forms a neat line 1 foot retired from the box or other edging. The plant should go as deeply into the soil as it was before it was removed.

Tarragon is early on the move, and new plantations may be made by digging up the roots and dividing and planting the divisions on a fresh piece of ground. It will stand a good deal of shade under fruit-trees, and should not be much manured.

Spear and Peppermint may be similarly treated.

Digging Land.—In trenching any but the oldest kitchen gardens, or unusually deep soils, the subsoil should not be brought to the surface in any but the smallest quantity, or the fertility of the land will be impaired for several years. The following is a good method of trenching: having taken two good crops off the surface soil, trench the land three spits deep if it will bear it, by which the top and the bottom spits are reversed, the middle spit of soil remaining in the middle, then take three crops off the surface soil, digging it only one spit deep; and having done this trench it two spits. The top spit has now become the middle one, and the middle the top; again take two crops, and then trench three spits deep, by which procedure that that was the middle spit becomes the bottom one, and the bottom, which was the surface-soil at the beginning of the series, after having laid for four years untouched, comes to the surface. By this means good crops of roots and vegetables are obtained without annual dressings of animal and vegetable manures, and air and water have ready access to the soil.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Adiantum cuneatum.—Those plants from which the more useful fronds have been cut, and have been kept somewhat drier at the roots, may now be repotted, some of the larger plants may be split up for stock, although plants from spores are preferable, as growing with more freedom. Plants which are in good health and have not stood any great length of time in the same pots, perhaps do not require a shift, and providing the drainage is in good order, they will make a satisfactory growth with the aid of mild manure-water afforded when growing. As a potting compost for Adiantums, use fibrous loam of good quality two-thirds, and leaf-mould one-third, and sand and charcoal in quantities sufficient to keep the soil porous and sweet, drainage being an essential point. When shaking out the plants, a pointed stick should be employed to loosen the matted roots and remove the soil. Before repotting, give them a dusting with sand, and take care that the soil is pushed down the bottom betwixt the ball and the side of the pot. Place the repotted plants in a brisk, moist heat, and afford water sparingly till growth has freely begun. As other plants become shabby-looking, cut the fronds over, keep the soil somewhat dry for a time, and then treat in the manner I have described.

Pteris serrulata.—Young plants of the type and the crested forms, if growing in small pots, may be shifted into larger pots and placed in a brisk heat, when they will rapidly make decorative specimens of a useful size. Spores may be sown on sterilised peat in order to keep up the stock of plants, throwing away the large old plants when no longer of decorative use.

Nephrolepis exaltata.—Where large quantities of Fern fronds are needed for cutting, this useful Fern might be extensively grown with advantage, and young pieces are readily obtainable from the sides of baskets, from the rockwork in the fernery, or by breaking up the old plants. There is no difficulty where a small stock exists in increasing it. Divided plants may be placed for recovery in an early vinery, or similar house in which a moderate degree of warmth is maintained.

Asparagus plumosus, &c.—These plants need timely attention, as growth recommences early in the

year. *A. plumosus* and *A. p. nanus*, two of the more useful varieties for decoration or for cutting, which are much cut over, may be repotted, using 6-inch pots for ordinary purposes; but if specimens are required, larger pots are necessary. In order to increase the stocks of these plants, the roots may be divided, or cuttings taken off the main stems, each with a leaf, may be inserted singly in thumbs in a sandy soil, and after affording water, place the cuttings under a hand-glass in a brisk bottom-heat. From those cuttings inserted at this date, plants of a useful size and in 4 or 5-inch pots may be obtained by the beginning of the autumn. Bare parts of the back-walls of vineries, stoves, or any position which will permit the growths to be trained on wires or strings, may be covered by setting out old plants of *A. plumosus* or *A. tenuissimus*, the former being the more useful variety. *A. decumbens* of gardens, when grown in a wire basket, makes an elegant plant for hanging in the conservatory or fernery. The stocks of these plants may be increased by division of the roots, and good lumpy pieces of fibrous loam, leaf mould, and sand, form a suitable compost to use; a layer of moss being used to cover the sides of the basket. *A. racemosus* is a variety that is found of use for affording foliage for cutting, or as a decorative plant.

Myrsiphyllum asparagoides, growing in pots and which is denuded of most of its growths, may be repotted or divided forthwith if an increase of stock be required; good results are also obtained by sowing seed early in this month in brisk heat, and pricking off the seedlings into thumbs when large enough to handle, and finally affording them a shift into 5 or 6 inch pots. A similar position and treatment are advised for this plant as for *Asparagus plumosus*. If planted out, it is advisable to lift them in alternate years, and reduce the size of the plant somewhat before replanting; add a little fresh soil, not too rich, or the growth will become coarse and less well adapted for decorative purposes.

THE HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Digging.—All fruit-tree borders should be dug without delay, in order that the rain and snow may penetrate the soil without hindrance before dry weather commences. This is especially necessary with wall-tree borders which get trodden very hard. If the trees will be benefited by manuring, afford rich farmyard dung in a decayed state before beginning to dig. If the pruning and nailing of the trees cannot be finished before digging the border, broad planks or wooden trellises should be used by the men engaged in these operations.

Bigarreau and Duke Cherries.—Those wall-trees which were properly pruned in the summer will need but little more at this season, and it will suffice to shorten the points of those branches that were laid in at their full length by one-third, and in this manner encourage the formation of fruiting spurs. The foliage of these varieties of the Cherry is large, and therefore the branches and shoots should not be less than 4 inches apart. Young shoots that were cut back somewhat in the summer in order to form fruit-spurs must be still further reduced to 2 inches in length; and spurs which have got very long should also be shortened. Let the dead leaves and other rubbish be cleared out from behind the branches, as this offers hiding-places for aphides and other pests. Any parts of a tree affected with gumming should be cleaned and dried with a hot iron, and then covered with grafting-wax or Mastic l'homme Lefort. This disease is sometimes fatal to Cherry-trees, and great care should be exercised so as not to bruise the bark when nailing. Standard Cherry-trees need but little pruning, all that is necessary being the removal of crossing branches; and in the case of young trees, the shortening of the main branches to 9 inches in length until a good foundation for the head is obtained, and five to seven shoots of equal strength are sufficient for this purpose. The weaker shoots should be shortened to 2 inches. Cherry-bushes that have attained to full size will require that their young shoots be shortened to 2 inches, and the long spurs attended to. It is better to keep these bushes of a convenient size for netting than to let them become large. In places where Cherries fail to stone, and they fall from the trees at an early period, a heavy dressing of lime-rubbish or of slaked lime should now be forked into the borders, but lime made of magnesian limestone must not be used; and finely broken chalk, if it can be obtained, is better than anything else.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, FEB. 8 { Royal Hort. Society's Committees
and Annual Meeting.

SATURDAY, FEB. 12 { Royal Botanic Society—General
Meeting.

SALES.

TUESDAY, FEB. 8 { Carnations, Perennials, Conti-
nental Plants, &c., at Protheroe
& Morris' Rooms.

WEDNESDAY, FEB. 9 { Japanese Lilies, Tuberoses, Conti-
nental Plants, Roses, Bego-
nias, Gladioli, &c., at Protheroe
& Morris' Rooms.

THURSDAY, FEB. 10 { Roses, Fruit Trees, Shrubs, Bulbs,
Border Plants, at Mr. Stevens'
Rooms.

FRIDAY, FEB. 11 { Imported and Established Orchids,
at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—39° 2°.

ACTUAL TEMPERATURES:—

LONDON.—February 2 (6 P.M.): Max., 53°; Min., 42°.

PROVINCES.—February 2 (6 P.M.): Max., 45°, south-west counties; Min., 35°, north-east Scotland.

Weather colder; strong wind.

A "mixed"
method of
Grafting.

THE relation between the stock and the scion is a subject to which reference has frequently been made in these columns. What is known as KNIGHT'S law, which VAN MONS expressed still more clearly, asserts that "only its own nature controls the development of the scion." It has, however, been proved that the statement is not universally true, and that the scion and the stock mutually influence each other more or less. Sometimes one predominates in influence, and sometimes the other; and a very important series of experiments in this connection is contained in VÖCHTING'S *Ueber Transplantation am Pflanzenkörper*, which was published a few years ago. Much additional and corroborative information has since been recorded by various observers, more especially perhaps by Prof. DANIEL, of the University of Rennes, in Brittany, who, in the *Comptes Rendus* (t. cxxv., No. 18), has lately given on this subject an elaborate account of recent experiments, which are all the more important, inasmuch as they tread on what may be called new ground in the field of the graft.

M. DANIEL mentions at the outset that in the ordinary methods of grafting, care is taken as a rule to suppress all the shoots of the stock at the time of the operation. Occasionally, and in order to facilitate the rise of the sap to the level of the graft, a bud or a few leaf-bearing shoots are retained at the apex of the stock. This procedure is, however, always of a temporary character, and the removal of all growths of this nature is effected after the graft has "taken," because, as is commonly said, the

existence of the scion would be seriously compromised by the more rapid development of the stock itself. M. DANIEL asserts that no attempt had ever been made to observe the effect of leaving a certain number of shoots on the stock, and keeping their development within bounds so as to preserve the life of the scion. He commenced his experiments on the hypothesis that different results should be obtainable—as regards the success of the operation itself, and also in respect to the reciprocal reactions of the scion and stock—if it were possible to maintain an artificial equilibrium between the parts, which would then simultaneously assimilate, and elaborate sap derived from one and the same source. M. DANIEL calls his new method the "mixed graft," to distinguish it from the other ordinary systems.

He states that whilst it is an easy matter to graft successfully plants with persistent leaves on certain other plants whose leaves are non-persistent, the inverse method is difficult, if not impossible; inasmuch, as the stock, when it is deprived of its persistent leaves by the ordinary process of grafting, exists in the winter practically at the expense of the scion which, being itself leafless by nature during the same period, is unable to render the necessary help. To this cause, M. DANIEL attributes the failure of the "ordinary" method in this connection.

In the spring of 1891, M. DANIEL grafted the wild Cherry (*Cerasus avium*) on the Cherry-laurel (*Prunus lauro-cerasus*), leaving on the stock certain shoots of which the young leaves were pinched back as soon as their development assumed proportions prejudicial to the scion. In the following year, too large a number of leaves was intentionally left on the stock, with the result that the scion suffered both in its development and from insect attacks. When, however, the stock was subjected to severe pruning, the scion was restored to its normal conditions, and when in subsequent seasons, the number of leaves left on the stock was proportionate to the growth of the scion, a perfect equilibrium between the two plants was obtained, and their growth was normal. The scion, moreover, has since borne fruit on two occasions, and some of its shoots have attained a length exceeding 1 yard annually. M. DANIEL therefore considers this union to have been completely successful, and he is of opinion, at any rate in the case of the two plants above-mentioned, that the "mixed method" offers a better means of grafting a tree with non-persistent leaves on an evergreen.

Another series of experiments was undertaken by grafting two different kinds of Haricot Beans. The grafting of Haricot Beans, as well as of other hollow-stemmed plants, had apparently been considered impracticable until M. DANIEL at the "French Association" meeting in 1892 announced its possibility by grafting the plants during the period of germination. In order the better to observe the differences between the "ordinary" and "mixed" methods in this connection, M. DANIEL selected two varieties with maximum characteristic differences, viz., the Black Belgian and the Soissons Haricots. The former is a dwarf and somewhat early plant, with a short inflorescence, bearing from three to five violet flowers, yielding two or three pods, which are tender and agreeable to the taste, and bearing dark-violet, medium-sized seeds. The Soissons Bean, on the other hand, is a Runner Bean, and a much later plant; its long inflorescence bears about twenty pale yellow flowers, with three to five coarse

Pods of a disagreeable taste, and its seeds are white and large.

Mr. DANIEL experimented with plants growing side by side under exactly similar conditions, in order to obtain comparative results of the two different methods of grafting, and he also grew plants of each variety under normal conditions, so as to serve as checks on the variations obtained. The results are shown in the following tabular statement:—

	Black Belgian Haricot.		Black Belgian Haricot on Soissons Haricot.		Soissons Haricot.	
	Not Grafted.	"Ordinary Graft."	"Mixed Graft."	Not Grafted.	Not Grafted.	Not Grafted.
Height	0.40 metres.	0.25 metres	0.40 metres	4.50 metres	4.50 metres	4.50 metres
Leaves	Numerous and vigorous.	Less numerous, paler green, and less vigorous	Very numerous; very large	Very numerous; very large	Very numerous; very large	Very numerous; very large
Flowers	Violet (all).	Violet (all)	Some violet, others variegated white and violet.	Pale yellow	Pale yellow	Pale yellow
Flower-stalks	Short; three to five flowers, two or three pods.	Short; two or three flowers, one or two pods.	One long stalk, bearing nine variegated flowers. The others short, similar to the "check" plant. The long one bore three pods.	Long; about twenty flowers; three to five pods.	Long; about twenty flowers; three to five pods.	Long; about twenty flowers; three to five pods.
Pods	Tender, not stringy; taste very agreeable.	Slightly stringy; slightly like Soissons Bean in taste.	Partly stringy, with pronounced taste of Soissons Bean.	Stringy; taste peculiar, and very disagreeable.	Stringy; taste peculiar, and very disagreeable.	Stringy; taste peculiar, and very disagreeable.
Seeds	Dark violet.	Dark violet	Dark violet	White	White	White

The conclusions drawn by M. DANIEL from these experiments are as follows:—

The "mixed method" of grafting should be adopted to ensure more easily the union between plants of marked physiological differences, as in the case of persistent and deciduous leaves.

The direct influence of the stock on the scion is not identical in the "mixed" and in the "ordinary" methods. Those phenomena which may be considered due to variations in the surrounding conditions, as are the size and relative vigour of the scion, are less marked in the case of the "mixed" method. On the contrary, certain characteristics of the stock, such as its taste, the shape of its fruit, and the colour of its flowers, are much more easily conveyed to the scion by the "mixed" method, which should be used when it is desired to obtain by means of the graft new varieties possessing certain particular characteristics; or, in other words, to make the scion or its posterity acquire certain qualities of a given stock. Conversely, when the aim is to maintain the purity of the variety to which the scion belongs, the "ordinary" methods should be adopted, leaving, moreover, on the stock the smallest possible proportion of green parts—that is to say, to operate as near the root as is possible.

CROCUS ZONATUS.—A lovely autumn-flowering species, which grows in loamy soil, and commonly found in the Cedar and Juniper forests; often also in the Alpine region of the Cilician Taurus. The flowers are of a silky, pale violet colour, with distinct golden-yellow marks in the base. The illustration furnished by Mr. SIEBE (fig. 31) shows the plants as growing wild.

ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral Meeting of the Royal Horticultural Society will be held on Tuesday, February 8, in the Drill Hall, James Street, Westminster, 1 to 4 P.M. At 3 o'clock the Annual General Meeting of the Society will be held in the Lindley Library, 117, Victoria Street, S.W.

M. CH. DE BOSSCHERE will treat of Orchids both in the French and in the Flemish languages. Mr. DE BEUKER will lecture on plants grown in apartments, and on town gardens. M. DE BOSSCHERE will also lecture on the art of arranging flowers. The dates fixed at present are January 30, February 6, Feb. 13, Feb. 27, and March 6, at 11 A.M. at the Zoological Garden. Further particulars may be had from M. VANDERLINDEN or M. ANATOLE DE COCK, the Secretaries.

JOHN LINDEN.—On the 12th inst., the *Semaine Horticole* will publish a full account of the career of the late eminent collector, accompanied by a portrait taken from one painted by his son, M. GASTON LINDEN.

1898, at half-past 6 o'clock precisely. The Council are inviting many distinguished persons as official guests.

FORESTS OF SIAM.—Langsuan, a district of Siam whence tin is obtained, produces the various kinds of fruit common to most Malayan States, the Durian, the Papaw, Mangosteen, Mango, Orange, Jack-fruit (*Artocarpus*), Melon, the Banana and others. The climate is hot, damp, and very unwholesome. "There lives in the dense jungle," said Mr. Warrington Smyth, at a recent meeting of the Royal Geographical Society, "a peculiar plant known to botanists, which is called by the Siamese Kalungton-chang, and which sets up great irritation in the skin

FIG. 31.—CROCUS ZONATUS: FLOWERS OF A SILKY PALE-VIOLET COLOUR.
($\frac{1}{2}$ nat. size.)

HORTICULTURAL CLUB.—The twenty-third anniversary dinner will take place on Tuesday, February 8, at the Hotel Windsor, Victoria Street, Westminster, S.W. The chair will be taken by Sir J. D. T. LLEWELYN, Bart., M.P., chairman of the Club, at 6 P.M.

NATIONAL ROSE SOCIETY.—Offers of special prizes are earnestly requested, as the General Purposes Committee will meet shortly to prepare draft copies of the schedule for the year. Such prizes will be more than usually welcome, owing to the sum available for the Crystal Palace show being much smaller than in the previous year.

ROYAL HORTICULTURAL AND AGRICULTURAL SOCIETY OF ANTWERP.—The Society has established a series of lectures on horticultural subjects, thus:

SEEDSMEN'S ENTERPRISE.—It appears that we were not sufficiently well informed when we commented on the apparent want of enterprise of our seed-firms. Messrs. CHARLES SHARPE & Co. (Lt.), now send us catalogues in French and German, with the prices and quantities given in terms which foreign purchasers can understand. No foreigner could make head or tail of our own idiotic weights and measures.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, February 7, 1898, when the adjourned discussion on the paper read by Mr. A. HUDSON (Associate), at the last meeting, entitled "Technical Tribunals and Surveyors as Arbitrators," will be resumed. The chair will be taken at 8 o'clock. The Annual Dinner of the Institution will take place at the Holborn Restaurant (King's Hall) on Wednesday, February 9,

of any person coming into contact with it. It has a large broad leaf, and the Siamese declare, after being badly stung by it, the only remedy is the heat of a fire; to bathe in a stream, which is the natural impulse, is considered absolutely fatal." Probably this is some Urticaceous tree, but the description "a large broad leaf" lacks amplitude.

LONDON PARKS AND OPEN SPACES.—Sir JOHN HUTCHINSON, a former Chairman of the London County Council, in the course of an address on "Some of London's Municipal Facts and Figures," gave some interesting details as to the growth of open spaces in London during the past ten years. The London County Council, which was constituted under the Local Government Act of 1888, came into power in 1889, and at that time London possessed only forty parks and open spaces, with an acreage of 2,656. At

the present time London has seventy-nine parks and open spaces, so the number has practically doubled during the last nine years. The acreage is now 3,685, an increase of over 1,000 acres; neither of these items of acreage include what are known as Royal Parks, as Sir JOHN was dealing only with those under the control of the London County Council; the actual result is the addition of 1,029 acres during the past nine years. By comparing this added acreage with that of the Royal Parks, some idea is gained as to what this added acreage really means. Hyde Park is 400 acres in extent; Regent's Park and Primrose Hill combined amount to 450 acres; the Green Park, adjoining Piccadilly, 71 acres; and St. James' Park, 83 acres. These figures totalled up amount to 1,001 acres; so the added acreage of parks and open spaces provided by the London County Council since its formation more than equals the whole extent of the four royal parks, the extent of the latter being 20 acres short of the total increase since 1889. The cost of maintenance is £105,000 per annum, which roughly speaking comes out at about £28 per acre, certainly not too large a sum when one considers how well they are kept, and what an enormous boon they are to the community. Sir JOHN HUTTON can boast, with justifiable pride, that during the three years he was chairman of the Board the large majority of these new additions became added possessions. It should not be forgotten that the immense zone which is known as greater London, lying beyond the circumference of the area governed by the London County Council, has, during the past fifteen years or more occupied itself in also adding to its open spaces. London grows in every direction, and local governing bodies are fully alive to the necessity of making this provision to the great advantage of the several localities particularly interested.

— The EARL OF MEATH as President of the Metropolitan Public Gardens Association, has addressed a letter to the *Times* on the subject of the maintenance of the smaller pleasure-grounds of London, and discusses the question, whether they shall be maintained wholly or in part by the London County Council, or by the local authorities. "The open spaces in London of less than 10 acres in extent, which are at present kept up for the enjoyment of the public, number 208, aggregating 366½ acres. Of these the London County Council at present maintain 42. Many of the London district boards, vestries, and burial boards are keenly interested in the maintenance of open spaces, and are very successful in their management. For instance, Hackney keeps open 19 such grounds, Islington 10, and St. Pancras 8, whilst 34 other similar bodies, including the City of London, are responsible between them for the maintenance of 77 grounds." The Earl concludes his remarks thus—"It is to be hoped, therefore, that the London County Council, whilst contributing towards the cost of the maintenance of all small public open spaces within the metropolis, will, as far as possible, leave their management in local hands."

A BOTANICAL GARDEN FOR ABERDEEN.—A serious deficiency in the equipment of the University (a deficiency in which it stands alone) is the want of a garden to provide means and opportunity for the study of living plants, and to render possible the efficient teaching of vegetable physiology, which is required by ordinance as an essential part of botany in the final examination for the degree of B.Sc. The recent institution of degrees in agriculture renders the necessity for such means of instruction more pressing. A small botanic garden might be suitably provided near King's College at little cost. More than a century ago it was proposed to set aside a "spot of ground" behind what is now the Biblical Criticism Manse for a botanic garden, as being "uncommonly well adapted by the variety of soil it contains, its command of water, its sheltered situation, and its nearness to the College;" but financial difficulties prevented the project from being carried out. The same spot of ground would still be suitable; and, on a representation recently made with regard to it by the Professor of Botany (who was, however,

then unaware of the earlier proposal), the University Court, while regretting that the state of the University funds did not meantime permit of the proposal being carried out, recognised the necessity of some such provision being made as soon as possible. The first cost of laying out the ground may be estimated at £200; and the annual expense of maintaining it with rigid economy, as an open-air garden without green-houses, at £100, which capitalised at thirty-three years would amount to £3300—in all, say, £3500.

KENSINGTON PALACE.—The most beautiful portion of the whole group of buildings, says the *Times*, is the Orangery, a long garden-house which was built by Sir CHRISTOPHER WREN towards the end of his life, and which bears Queen ANNE's monogram. It is in red brick, and so far as the south front and the ends are concerned, is in admirable preservation; but the exquisite interior has been the victim not of neglect, but of chronic outrage. For, as the little garden between this and the Palace has been found a convenient place on which to put up the glasshouses, frames, and potting-sheds necessary for the park-gardeners, what more natural, to the official eye, than that the Orangery close by should be pressed into the same service? Accordingly, at some time or other, which cannot have been very many years ago, more than half the beautiful high Oak-panelling of this building was torn down and has disappeared; the gardeners' stands have been let into the walls, and there the daily work has proceeded with no thought that it was a daily desecration. Fortunately, it is not beyond the skill of a modern wood-carver to work from WREN's models as well as WREN's own men could do. When that is done, and when the floor has been relaid—whether in concrete or Oak appears to be not yet decided—this will be one of the loveliest buildings of the late Renaissance period to be found in England. It is proposed, we believe, to put it to no active use, but to make it just a resting-place and a refuge from the weather for any visitors to the gardens. But, that the impression may be complete, it will be positively necessary to remove the greenhouses to another quarter, perhaps to the neighbouring meadow, where they would be fairly out of sight, and the ground on which they stand must then revert to its original intention and be laid out in walks and flower-beds.

THE ROYAL GARDENERS' ORPHAN FUND.—The monthly meeting of the committee took place on the 28th ult., at the Hotel Windsor, Mr. WILLIAM MARSHALL presiding. The following special donations were announced:—Scottish Horticultural Association, £50; Royal Caledonian Horticultural Society, £26 5s; Chesterfield Gardeners' Association, £5 18s. 4d; Mrs. Wills, 16, Onslow Crescent, £5 5s; Messrs. W. Thomson & Sons, Clovenfords, box, £4 5s. 4d; Mr. J. H. Vallance, Bristol, £4; the Leeds Paxton Society, £2 15s; Mr. H. Herbst, Kew Road, Richmond, £2 2s; Mr. J. Smith, per Mr. J. Wright, £2; Mr. George Fry, Lewisham, box, £1 3s. 5d; Messrs. J. Veitch & Sons, box, £1 2s. 8d; the Bournemouth Gardeners' Association, box, £1 1s; Mr. G. Nicholson, Kew, box, £1; Miss Forrest, Anderton's Hotel, Fleet Street, box, £1; Mr. T. Turner, R.H.S. Gardens, Chiswick, box, 15s. 8d; Mr. J. Selway, Betteshanger, 17s. 4d; Messrs. H. Cannell & Sons, Swanley, box, 11s; Mr. J. Miller, The Gardens, Ruxley Lodge, Esher, 10s; the young men at Ruxley Lodge Gardens, 10s; Mr. A. D. Christie, Ragley Hall Gardens, Alcester, 7s. 6d; young men at Fairlawn, Tonbridge, 7s. 6d; and the Chislehurst Gardeners' Society, 6s. Great satisfaction was expressed at the very handsome donations from the two Scottish horticultural associations. A draft report and also a financial statement, were adopted for presentation at the coming annual meeting. Some letters of deep thankfulness were read from the mothers and guardians of children, who, by reaching the allotted age, have ceased to be chargeable to the Fund. One passage in the report touches on the timely help afforded to children who have been on the Fund, in the way of assistance in getting a start in life. The

annual dinner is fixed for Wednesday, April 20, and will take place at the Hôtel Métropole, CHARLES KEYSER, Esq., Warren House, Stanmore, presiding. This being the last meeting of the committee previous to the annual general meeting, a hearty vote of thanks was passed to the Chairman for his services during the year.

THE AUSTRALIAN KITCHEN GARDEN.—By FRANK FINEDON (George Robertson & Co., Melbourne, Sydney, Adelaide, Brisbane, London). A book destined to give "reliable information in handy form" cannot fail to prove of great value, and this is certainly the case with the volume before us. Some idea of the subject-matter may be gleaned from the table of contents, where under the heading of management we are referred to information concerning tools, frames, hot-beds, and horticultural operations such as seed sowing, watering, &c. Varieties and Treatment is the heading to the instructions for growing vegetables (from Artichokes to Vegetable-Marrows); miscellaneous crops include Arrowroot, Castor-oil Plant, Chinese Yam, Liquorice and Tobacco; while land measure, a monthly calendar of operations, and a sheet calendar are last in place but not in value. Various illustrations brighten the pages, and the detailed information given respecting every variety of vegetable mentioned (alphabetically), is furnished by a highly competent authority. Salad plants, we note, receive special treatment in Mr. FINEDON's book.

THE NORTH PECKHAM AMATEUR CHRYSANTHEMUM SOCIETY held its annual dinner on the 27th ult., the proceedings being markedly enthusiastic, and the prospect of special and other prizes for competition during the present year, are very encouraging.

PUBLICATIONS RECEIVED.—*The Rural Monthly*, 18, Cheapside, E.C., Jan., 1898. The first number of a new journal with the sub-title: Small Farms Agency and Producer and Consumers' Advertiser.—*Proceedings of the Agri-Horticultural Society of Madras*, July to September, 1897, includes papers on Opuntia as Cattle Fodder, Rubber-plant Seed, Mangosteen, Carrot Seed, &c.—*The West Australian Settlers' Guide and Farmer's Handbook*; Parts I. to IV.—*National Footpath Preservation Society*; Thirteenth Annual Report. The report endeavours to do justice alike to the landowner and the wayfarer. Undoubtedly much damage is done by thoughtless people, but not by naturalists.—*Delectus seminum ex horto Cantabrigiensi Academia ad mutuam commutationem propositorum* (Exchange Seed-list Cambridge Botanic Gardens), R. I. Lynch, Curator.

HOLKHAM.

A PERFECT model of an Italian garden forms part of the beautiful environment of the house, whose principal approach is from the south, the main entrance being through a noble portico of Corinthian columns. Here, in an oval sheet of water, is a fine ornamental fountain, with a group in the centre representing St. George and the Dragon. Three columns of water issue from the dragon's mouth, and form an excellent fac-simile of the Prince of Wales' feathers. The water on the estate is drawn from an artesian well 750 feet deep, and the site of the well is only 30 feet above sea-level. In the pleasure-grounds are three large Pines, which are probably the oldest in England. It was understood that the seed was brought to Holkham from Corsica, and it was always believed that the trees were *Pinus Laricio*, which has twisted leaves, occasionally 6 inches long. Both on the ground of the tradition associated with the seed, and the appearance of the trees themselves, Mr. Munro, who is no mean authority, accepted the belief that they were *Laricio*, but the consensus of opinion on this occasion was that they are *austriaca*; and in several other parts the Corsican Pine was pronounced to be a variation of the Austrian, and not *Laricio* at all. One of these trees has a girth of 30½ inches (quarter girth), and is about 90 feet high. Another is a foot less in girth, but towers to a height of over 90 feet.

Most of the Pines hereabout were grown from the seed of the older trees. Here we saw an *Abies Pinsapo* and *Cedrus atlantica* in cone, and a Portugal Laurel in seed. A *Cedrus Libani* close by is 30 inches quarter girth (under bark), and a *Wellingtonia* is 33½ inches, and 65 feet high. A Tulip-tree, an *Acer Negundo variegatum*, and an *Abies cephalonica* (the latter 45 feet high, and in perfect health) were also noted. Growing outside in the gardens were well-fruited Fig-trees, and Tomatos were fruiting freely in the open. There are 6 acres of enclosed garden land, and a corresponding acreage of orchard, with ranges of conservatories, vineries, and other glass-houses for exotic plants and fruits. Of the 3200 acres enclosed

GEORGE FRY.

We have much pleasure in publishing, from his own pen, a few salient particulars in the life of a celebrated gardener and nurseryman, and most estimable man. Many of our readers will be acquainted with his name only as being the raiser of numerous varieties of Fuchsias in the early forties and later, although to the younger generation of gardeners Mr. Fry is practically unknown out of his own neighbourhood—but we will let Mr. Fry tell his story in his own way:—

"I commenced my career in the early thirties, and when the first gardener's newspaper came out,

this general routine of garden practice; and when there has been deep snow and keen frost, I felt proud in being a young gardener. At this time I took in Macintosh's *Practical Gardener*, and thought nothing of running about two miles in my dinner-hour to obtain the monthly number or part; this was when I was about sixteen years of age, and what little money I got all went for gardening books.

In 1846, by the advice of Dr. Lindley, Editor of the *Gardeners' Chronicle*, I registered my contrivance the 'West Kent Garden-pot,' having shown that gentleman a model at 21, Regent Street, London, where the meetings of the Horticultural Society used to take place. I sold my rights in the patent to Mr. Pascall, of The Potteries, Chislehurst, and handed him two ten-pound orders, one from Mr. William Barnes, who has been described as the father of plant-growers, and whose fame was well known as such at the grand shows at Chiswick; the other order was from my old and highly-esteemed friend, the late Mr. W. P. Ayres, gardener at Brooklands, Blackheath, who was at that time an able contributor to the *Gardeners' Chronicle*. From this time I was frequently attending the meetings at 21, Regent Street, about 1850, with what was described as a self-acting fumigator, the original sulphurator, and the fumigator and sulphurator combined. About 1855, engravings with description may be seen in the *Gardeners' Chronicle* of my patent Seakale propagating-pot and Fern-pans. My mode of growing bedding plants in turf, both in pits, frames, and also in boxes. These articles appeared in the *Gardeners' Chronicle*, April 24 and May 15, 1852, with a facsimile of the instrument used for perforating the turf.

One of the very interesting periods of early life was in 1842, 1843, 1844, when I was engaged as under-gardener at John Angerstein's, the Woodlands, Blackheath, at one time one of the finest places in Kent, and noticed by the truly gifted and noble-minded man, John Claudius Loudon (who inserted the very first article written by me), during the short time that he was editor of the *Gardeners' Gazette*. In giving brief descriptions of noblemen's and gentlemen's places throughout the United Kingdom in his stupendous work, viz., the *Encyclopædia of Gardening*, published in 1827, thus, 'Woodlands, near Blackheath, J. J. Angerstein, Esq., an elegant mansion of Portland stone, in a commanding situation, the grounds agreeably varied, and the gardens remarkable for the quantity of glass they contain. There is a very large conservatory, and numerous vineries, the invention and execution of Mr. D. Stewart, when this gentleman's gardener. Also an excellent collection of exotics.' During the latter part of the time I was at the Woodlands, which was then in the possession of John Angerstein, the son of the former John Julius Angerstein, I had been removed from the kitchen garden, fruit, and forcing department, and put in charge of the large conservatory, plant-house, and pleasure-grounds. In the conservatory was growing one of the first *Araucaria excelsa* that was introduced into this country, which, after reaching 30 feet, had the top cut off, having reached the glass roof. On the columns in the centre of the conservatory, hidden by the large shrubby plants, I was much interested in reading the names of many young men who had been employed here, and removed into other situations. Sweet, subsequently the eminent botanical writer and author, I was told, was at one time an under-gardener in this old place, which is no more to be seen, as its beauty was destroyed—in fact, completely annihilated. The Peach-houses and vineries in which I had to work have long since been cleared away. I may mention, that it was at this time that I was induced to take the Fuchsia in hand, and succeeded in producing many good specimens in large-sized pots, which used to decorate the terraces outside, and also grown in the inside of the conservatory. These were only species when I entered the arena of gardening, and at this time varieties (good ones) were not so very numerous; that old trite adage, how true it proves, that 'every dog has its day;' old loves have to give place to new ones. Such is our transitory state and natural condition, plants which have been

GEORGE FRY.

by park walls, over 1000 acres are woods and plantations; while there is a pretty lake, about 1000 yards long, with three islets, haunted by waterfowl of English and foreign breeds. From the pleasure-grounds we drove on to the Obelisk Wood—a wood which takes its name from a stone column 80 feet high, on the main drive leading to the south lodge. The Obelisk was erected in 1729, a few years before the building of Holkham House was commenced. It was close to the Obelisk that Mr. Munro pointed out to us the largest of the evergreen Oaks. In the wood of that name are several large Beeches. One of these measures 31 inches quarter girth, and has a fine clean bole; it was computed to contain 233 cubic feet of timber. Another Beech has a quarter girth of 32 inches, and is said to contain 350 cubic feet of timber. *Transactions of the English Arboricultural Society.*

which was published on January 7, 1837, I became a subscriber in the autumn of that year; and well I remember the winter of 1837—1838, and known or designated by some as 'Murphy's' winter, he having predicted the coldest night. The Royal Exchange was destroyed by fire on the night of January 10, 1838; the destruction of shrubs and vegetation generally was very extensive. Nevertheless, I was enabled to cut very handsome Cucumbers in the month of April following this rigorous winter; not the kind of Cucumber we grow now, but the old favourite ribbed Black Spine, that carried a beautiful bloom, like a well finished bunch of Grapes. At this time our early forcing was done mostly by fermenting material—good horse-dung and leaves. We had our handsome, clean Potatos early in the months of spring; also Radishes, Carrots, and all such things as required. All my early days were much occupied in

idolised and almost worshipped have to fall back into the ranks of generally cultivated plants as an ordinary subject. This, doubtless, is a judicious order of Nature's behest for the welfare of mankind in a commercial point of view, also physically and mentally. *George Fry.*"

"THE SUMMERS OF 1896-97: THEIR EFFECTS ON THE FRUIT- TREES AND FRUIT-CROPS."

IN reviewing the many-sided effects of the summers of 1896-97, the facts range themselves as favourable and unfavourable. The tropical heat, combined with drying winds, and that general absence of rain during the spring months of the period under notice, dried the soil to an unusual extent; and although in 1896 abundant autumnal rains fell, in 1897 the months of September and October were the driest known for years.

The effect of the heavy rains of the autumn of 1896 was felt in the activity of the sap and the adhesion of foliage on fruit-trees rather later than usual, and consequently the trees did not get that rest which is as necessary for the vegetable world as for the animal creation; and we agree with Mr. R. D. Blackmore that the general failure of fruit-crops in the spring of 1897 was largely due to that cause.

The want of power in the trees themselves to lay up that necessary nutriment, and ability to perfect embryo fruit-buds, was arrested at a critical period, and as reported in the gardening papers, many cases of imperfect blossoms were noted in fruits, and doubtless many more facts would have been discovered had they been suspected and looked for.

To outward appearance the blossoms were perfect, the corollas being bold, as usual; but in many individuals either stamens or pistils were wanting, and no doubt also the upper or fruit nourishing roots suffered from the want of surface-moisture, and thus were prevented from doing their work—while lower anchor-roots struck deeper and deeper to gain moisture and sustenance for the development of the tree, making the subject less fertile, and adding gross wood to all garden trees, and thus trees were found to require root-pruning more than usual to restore that relative balance of fruit and wood-producing power which a well-managed fruit-tree should exhibit.

In orchards (especially among young trees) the want of fruit was a distinct benefit, as they are then enabled to form vigorous trees before starting to crop, and a foundation is thus laid for full development and after-success; as if a young orchard-tree commences to crop in its earlier stages, its after-growth is checked for years, and in the future such checked trees produce pecks where bushels of fruit should be garnered.

In the dry autumn of 1897 matters were different, and the glorious and gorgeous colours of the foliage on Cherries, Peaches, and Nectarines, and the fine russet-brown of the Apple foliage, and the golden Plum-leaves, leads us to infer that Nature's work has been well and truly done, and with a fair spring a good all-round crop may be anticipated in 1898.

Although from a nurseryman's point of view the shorter and stouter growth fruit-trees made in 1896-97 meant some loss and extra expense in staking for standard trees, &c., still the growers cannot fail to be great gainers in having the wood of fruit-trees well ripened, hardened, and consolidated for future benefit as heavy frosts tell much less severely on such perfected trees. If this is felt in the south, how much more must it benefit planters who live in the midland and northern counties! The pretty fruit shown, by Mr. Dy, from Galloway, and the grand Pears from Mr. Divers, Belvoir Castle Gardens, sent to the Royal Horticultural Society, bear out this fully.

The fruit crop of the Jubilee year, 1897, will be noted in our minds for its remarkably high colour and development more than for great size. Many examples submitted to us have been beautiful beyond all former years; for example, crimson Blenheim Orange Apples, Warner's King, and other green Apples with scarlet flushes on the sunny side; and Comice and other Pears with

lovely red cheeks; while many Russets have lost their character and come out with golden skins, only broken here and there with russet. Many of the less hardy Apples as Lord Suffield, Ribston, King of Pippins, and Glout Morceau, Bergamot d'Esperen, Gansell's Bergamot, and other Pears have been so handsome and good, that planters have called for them freely, forgetting that they are not to be relied upon (as a rule) for freedom from canker, or quality. Their extra good appearance, flavour, &c., points a moral, and doubtless we ought to place these and similar good but variable Apples on walls or in warmer places. Apples of the type of American Mother, Melon, Scarlet Nonpareil, Allen's Everlasting, Duke of Devon, Sturmer Pippin, with those that do not always ripen well, as Calville Blanc, Boston Russet, Calville Rouge, Chatley's Kernel, Reinette du Canada, Dutch Mignonne Apples, with Beurré Diel, Bergamot d'Esperen, Olivier des Serres, Beurré Rancé, Beurré Baltet, President Osmonville, Easter Beurré, Zéphirin Grégoire, &c., Pears, would not be out of place on many walls which are well situated, and now devoted to a doubtful crop of Peaches or Nectarines, especially those old walls, unpointed and full of nail-holes one often sees in ancestral gardens, where choice Pears and Apples would flourish and give good results.

The extended use of large and handsome Apples for decoration should lead growers to place Peasgood's Nonsuch, Buckingham, Belle de Pontoise, the Queen, King of Tomkin's County, Twenty Ounce, Gascoigne's Seedling, &c. on walls for this purpose.

One special feature of the 1897 fruit crop was the general success of the British raised varieties, such as Nonpareil, Northern Greening, Wyken Pippin, Blenheim Orange, Devon Quarrenden, Yellow Ingestre, Stirling Castle, Wellington, Ecklinville, Kerry Pippin, Keswick Codlin, Winter Queening, Nanny, Hornmead's, Lane's Prince Albert among Apples; and Hessel, Althorp Crassane, Hacon's Incomparable, Bishop's Thumb, Pitmaston Duchess, Crawford, Aston Town, Eyewood, and Knight's Monarch, among Pears, causing a demand to arise for trees of many old and superseded kinds, which for market purposes are yet valuable.

The general crop on the Codlin and early Apples and Pears need only be noted to state the fact that such kinds have time to recover themselves after the fruit is gathered, and so prove regularly fertile.

Exceptional prices have been made of some fruits. In our district, Devonshire Quarrenden, Ingestre, and Ribston Apples (one grower selling 100 bushels of the latter as gathered at 14s. 6d. per bushel), while Cox's Orange Pippins made up to 25s. per bushel retail; and Wellingtons, with a Peach-like colour, made 10s. 6d. wholesale.

As might be expected, the heat and drought has caused all late Pears to ripen months before their usual season, and by the time this is in print many fruit-rooms will scarcely have a Pear in them; at present Olivier des Serres and Beurré de Jonghe with a few Easter Beurré from open trees are all we possess.

But we are inclined to think thorough ripening will allow us to keep Apples as late as usual, while they will certainly not be so large examples—in short, beauty will compensate for mere size.

Perhaps no outside fruit felt the grand weather of 1896-97 more than Peaches and Nectarines on walls. The trees made that reddish wood so dear to the cultivator's eye, and the crop set well; and the fruit where the trees were copiously watered, grew out to a fine size, and coloured to perfection, raising the almost lost hopes of many old gardeners to encourage them to persevere in their open-wall cultivation; those who had late Peaches made long prices, as the fruit under glass was forwarded by the heat, and thus made a market for the outdoor crop. Peaches and Nectarines are yearly more in demand.

We attribute the failure of the Plum crop to the causes already named, which by their surface-rooting nature, would naturally be affected more than deeper-rooting fruits.

We cannot refrain from again cautioning gardeners from relying on a few varieties for an annual crop;

and the best kinds for quality should be planted in various positions to ensure a return, and also to lengthen the season of each kind.

Market-growers naturally go in for the sorts favoured by the public, but we are inclined to think many less known but reliable croppers should be introduced.

Strawberries, Raspberries, and bush-fruits generally cropped where good deep cultivation was practised.

In conclusion, it is evident that cultivators should do all in their power to utilise all the sunshine possible, and the protection they possess added to careful thinning of boughs and fruit, and by giving liberal encouragement to the trees that crop, and not over-stimulating those that are barren. A paper read at a meeting of the Horticultural Club on Tuesday, January 11, 1898, by Mr. George Bunyard, V.M.H.

LUCULIA GRATISSIMA AND OTHERS.

ON Tuesday, December 22, 1897, I found a whole house, some 35 feet long, 10 feet wide, 6 feet high in front, and about 10 feet at the back, filled with this fine old but rarely seen plant. The bushy plants were smothered with their fragrant blooms. I have grown and frequently met with this autumn and winter-blooming plant on the back-walls of green-houses, vineries, orchard-houses, corridors, &c., in several gardens. And at the present time there is a nice plant in bloom in the well-furnished corridor in the Edinburgh Botanic Gardens. Not a few of us have also been more or less successful with it in pots. But this is the first time I have met with the *Luculia gratissima* in its proper position, that is as a standard, and the effect was gratifying as it was striking. The plants look venerable from great age rather than by reason of their size, and they were blooming profusely, and fully furnished without crowding the space allotted to them. They had more flowers per square foot than I have ever seen before, and were looking remarkably free from insects and healthy, not easy of attainment in *Luculias* during their flowering season.

Mealy-bug and thrip are the chief foes of the *Luculia*, and they need a good deal of dosing to effect their complete extermination.

Cleanliness is not only the parent of health for the *Luculia*, but the chief secret of success in growing the plant. Though as to the latter, there are several more. One of the chief is, to let well alone. Prepare a border of about equal parts of peat and loam, or a fourth of gritty silver-sand, leaf-mould, peat, and loam, say 2 feet deep, of any convenient size. The old idea was, the narrower, in reason, the better. Hence, the correct practice at one time was to brick off a limited area from 1 foot to 2 feet square, for the roots of the *Luculia*. There was a common belief that the plant should not have its roots disturbed after planting, nor allowed too much space in which to roam.

Its security of tenure seems to have been religiously respected at the fine old nurseries of Messrs. Cunningham, Fraser & Co., Comely Bank, Edinburgh. Mr. Fraser seemed rather uncertain as to the exact age of these fine plants. With the exception of the front path, and a few shelves, the *Luculias* had the house wholly to themselves. An occasional top-dressing with liberal supplies of water through the growing season were the chief points in culture. But a dry time after pruning was also important. I found, too, that the exact mode of propagation was looked upon as a trade secret. This is less to be wondered at when it is known that this firm supply most of the trade with *Luculias*. Seeds come from abroad, and no plant can well be easier raised from seeds if these be raised in warmth of 65°. During their early stages, however, they should be shaded from the sun; but seedlings seldom bloom from seed in less than three years, and there is some difference in the growth and flowering of seedlings. Hence, we are driven to employ cuttings, which few growers, however, succeeded in rooting freely. They have been tried in all stages of growth, with and without heels, in an infinite variety of temperatures

ALPINE GARDEN.

MORISIA HYPOGÆA.

AMONG hardy alpine plants of the order Cruciferae, this little species is well worthy of cultivation, there being scarcely any part of the year when a few blossoms cannot be found, although its proper period of flowering is July and August. The blossoms are produced in abundance, and are even now fully expanded on a sunny part of the rockery. They are borne singly on short stems, issuing from a tuft of deep green leaves, and are of a deep yellow colour. The plant grows but 3 inches in height, and requires for proper development a rich sandy soil. It is easily propagated from seed or cuttings put in during the summer. It is a native of Corsica and Sardinia, from which country it was introduced in 1833, and is

HOME CORRESPONDENCE.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Your leader in last week's issue is well timed, and it places facts referring to the Institution in a fair spirit before the public. There are three points in connection with this charity which one has to deplore, viz., the apathy shown by the lack of support afforded by gardeners; the large number of spoiled voting-papers by non-signature; and the election of non-subscribers. In perusing the official list of subscribers one finds that the larger number of gardeners' names are those of men who hold leading places, and but very few of those holding second grade situations. Reasoning by analogy, the former are less likely to require assistance than the latter, although the records of the Institution unfortunately show many exceptions. The great falling off of subscribers appears amongst the middle-class men, whose ranks, nevertheless, supply nine-tenths of the pensioners. It is these men who should have the claims of the Institution brought urgently and persistently before them, so as to arouse them from their present apathetic condition. Possibly gardeners from the very nature of their isolated lives, are more apathetic than some other classes of the community; anyhow, I have arrived at this conclusion, that if every man of the 6,000 gardeners could be canvassed, and the whole particulars explained in a friendly way, a large number of subscribers would be added. How can this best be done is the question; my answer is, by the formation of county auxiliaries. Take the example of one of the youngest auxiliaries, that of Worcester: half-a-dozen enthusiastic men put down five shillings each to meet the preliminary expenses, and in two years they forwarded about £250 to headquarters, including many annual subscribers and life members. If each county did likewise, what a splendid result would follow! Extreme men require extreme measures, and much as I hate coercion, I would carry the canvass into a yea or nay, from every gardener, nurseryman, or florist worthy the name, and his answer should be recorded faithfully. This could all be done with little trouble, if two or three energetic and enthusiastic men in each county would set it going. This would be infinitely better than grumbling, as "A. D." does, at the disappointments of the ballot. If he would use his well-known tact and ability, aided by his powerful pen, many subscribers might be added, and consequently there would be more pensioners, and fewer disappointments. Probably, the non-signing of voting papers was an oversight, the intention being to enable the Committee to make selection of candidates out of the multitude of distressing cases, in fact, all of them worthy. There can be no doubt, a large section of subscribers are very conservative as to exercising their votes, and would resent any change or loss of privilege. There is also rather a strong feeling, and rightly so, against placing non-subscribers of less than five years on the pension list, in preference to older persons who have subscribed for a longer period. It is to be hoped influential county gardeners will take the matter up seriously; and any little information or details will be cheerfully rendered by William Crump, Madresfield Court Gardens. [We have a large number of letters on this subject which we cannot publish, but of which we may be able to give a summary. ED.]

— In the case of the elections to the Royal Gardeners' Orphan Fund, the executive committee prints in bold type, just above the place for the signature of the voter, this sentence:—"Any voting-paper duly filled up, but unsigned by the voter, may be signed by a life-subscriber or member of the committee." By making this proviso, many votes are saved to candidates which would otherwise be lost. Signed papers, but without any indication how the voter intended his or her votes to be given, are, of course, rejected. If the committee of the Gardeners' Royal Benevolent Institution took power to do this, the loss of votes so much deplored would be prevented. Surely such power can be given to the committee without the slightest danger of its being abused. Your proposal that the committee should select the most pressing cases and propose them for election at the annual meeting would not only save the expense of voting-papers, but avoid any waste of votes. It is, at the same time, a proposal likely to create much difference of opinion. R. Dean.

THE MILD WINTER IN SOUTH DEVON.—As an indication of the mildness, so far, of the present winter, I noticed on January 17 the first flower open

FIG. 33.—MAGNOLIA CAMPBELLI: FLOWERS DEEP ROSY PINK, SHADING OFF INTO WHITE AT THE CENTRE.

closely, as the young shoots break but sluggishly if at all from the old wood. And as the plants bloom on the ends of the young shoots of the current year, unless they break freely there can only be a scant crop of bloom. The season to prune is shortly after the flowers fade, which may be timed for any season from October to January. And from then till the starting period in April or May, little or no water should be given to Luculias.

Hitherto I have said nothing of the one other species or variety, *L. Pinceana*, which this firm also keep, though I quite endorse Mr. Fraser's estimate of their merits, viz., that contrasted with *Luculia gratissima* at its best, *L. Pinceana* is not worth growing. Placed under similar conditions, however, *L. Pinceana* blooms, if at all, earlier, continues longer in flower, is white, the larger of the two, and mayhap yet more fragrant than its rose-coloured rival. *L. Pinceana* has also smaller, more glabrous and showy leaves than the more generally grown and freer-blooming *L. gratissima*. The last was first in the field, having been introduced from the temperate Himalayas in 1825, and the *L. Pinceana* from the Khasia Mountains in 1843. It is generally admitted that neither of the species have obtained the popularity which their obvious or latent merits, and especially their unique fragrance and late autumn or winter blooms warrant. D. T. F.

monotypic. A description of the plant is given by Robert Sweet in his *British Flower Garden*, series 2, t. 290, published during the years 1831—1838. E. S., Woking.

MAGNOLIA CAMPBELLI.

THOSE who have access to the fine *Illustrations of Himalayan Plants*, published by Sir Joseph Hooker, will remember the splendid plate of this noble species. That the artist did not exaggerate is testified by Mr. Gammie, who records the flower as measuring ten inches in diameter.

In this country, so far, it has proved a disappointment. In 1885, it first flowered in Mr. Crawford's garden near Cork, and afterwards in other gardens in that country. Now Messrs. R. Veitch & Son of Exeter favour us with a flower taken from a plant which has been growing in the open air in their nursery for the last twelve years. The tree is covered with flower-buds, and we hope it may be possible to protect them in the event of frost. The colour of the outer petals was a rich rose-pink. A coloured figure is given in the *Bot. Mag.*, Jan. 1885, tab. 6793, from a flower produced in Mr. Crawford's garden.

of *Doronicum plantagineum*; this usually with us here is at its best during March and April, and a large number of clumps in the herbaceous borders have always proved invaluable for cutting purposes. It is a very free and strong grower, and to those who in the early spring can use flowers of various colours for house-decoration, I say by all means have a good supply of this, and I am sure much satisfaction will be received. As it is natural to make rather long flower-stalks, the plants should be placed where a good row of shrubs will afford some protection from keen, cutting winds, otherwise the flowers are apt to be blown over, and consequently damaged. Side by side with this are some plants of *Ageratum*, which were put out last May and June, when the flower-garden and borders, &c., were bedded-out. These *Ageratums* have been in flower almost ever since, and good clusters of purple flowers can still be gathered. In the same border *Forget-me-Not* is flowering, truly an early reminder of the coming spring; whilst in a border just removed from these, good spikes of *Pentstemons* are still brilliantly in flower. *Carnations*, *Pansies*, *Wallflowers*, *Primroses*, *Mignonette*, *Violets*, and the common *Marigold*, beside buds of *Gloire de Dijon* Rose, give an impression of brighter days rather than mid-January, when there is a possibility of there being 20° of frost, and a thick covering of snow. Though we scarcely expect any intensity of frost now, the snow may come and remain some time yet. *W. Swan, late of Bystock Gardens, Exmouth.*

PASSIFLORA EDULIS.—I can fully endorse every word Mr. D. T. Fish writes on p. 52 in favour of *Passiflora edulis*, the editorial remarks notwithstanding, for it is a most delicious fruit and a valuable addition to the dessert, extending over a long season, and highly appreciated as such by many. Judging by the increase of inquiries respecting it and its culture, I trust that its cultivation is gradually extending. *Jno. Roberts.*

FRUIT JUDGING.—The remarks of "Cornubian" (p. 61) on this subject, so far as they refer to the Royal Horticultural Society's great autumn fruit shows, serve to make clear the meaning of his note in the *Gardeners' Chronicle* of January 1, p. 12. Consequently, I have referred to the report of the fruit show, held under the auspices of the Royal Horticultural Society at the Crystal Palace the first week in October, 1896, and published in the Society's *Journal* the following month, wherein we find classes were provided for leading varieties of Pears coming in for use during the six months following, the date on which the show was held, as pointed out by "Cornubian." Among these may be mentioned *Josephine de Malines*, ripe from February to April, twenty dishes being shown. *Easter Beurré*, January to March (twenty dishes), *Bergamotte d'Espéren*, January to April (fourteen dishes), *Doyenné du Comice*, November to December (thirty-nine dishes), *Winter Nelis*, November to January (twenty-five dishes). With regard to the above-mentioned and similar varieties of the Pear being staged in October in classes provided for them in the Royal Horticultural Society's schedule, or for that matter in any other society's schedule, I have no hesitation in saying that the question of ripeness cannot possibly be considered in making the awards in these classes; the finest all-round specimens of the respective varieties should, undoubtedly, be awarded the prizes offered. But in the case of Pears ripening in October, the case is quite different, the exhibitors staging ripe fruits of equal size and shape as those of the same varieties, but not ripe, taking the prizes as a matter of course. This is where the advantage of forwarding the ripening period of the fruit a week or two by artificial means comes in; and without resorting to artificial ripening of the fruit by one or two weeks, northern growers are unevenly matched in entering hardy fruit competitions with southern craftsmen. In like manner Pears may be ripened a week or ten days before the usual time, in order to prevent a break occurring in the daily supply of ripe Pears. The best and finest-coloured specimens of *Marie Louise* Pear which came under my notice were artificially ripened from the end of September, and until they ripened in the ordinary way on the shelves in the fruit-room a few weeks later, during which time several dozen fruits were in daily demand, and elicited frequent remarks upon their colour, and goodness of flavour, and earliness. "Cornubian" is not very clear in his remarks on the best collection of fruit being the one which covers the longest season, providing the quality is of the best throughout, adding, "and the sooner judges cease to be sensible to the

glamour of mere ripeness, the better and less artificial will be the methods of exhibitors." The "best collection" must necessarily always include ripe fruit throughout the period of time covered. Fruit-growers should never send "dead-ripe" fruit to a show nor to the dessert-table, because, as a rule, such fruit is unfit to eat the day after it has been shown or sent to the house. Fruit which is "dead-ripe" may properly be described as "over-ripe." There is a distinct and important difference between the flavour of ripe and "dead-ripe" fruit, a fact of which surely "Cornubian" must be aware. *H. W. W.*

FRUIT-TREE LABELS.—In reference to Mr. J. Mayne's remarks on this subject, and the editorial foot-note (p. 60), I beg to say that the lead labels there referred to, or, rather, similar ones, had been used by me during the twenty-five years I was at Longford Castle Gardens; and I should say—judging by the condition of the oak-case containing holes for the reception of the twenty-six letter-punches and ten numbers, in 1871, when I took charge of the said gardens—had been in use by my predecessors fifty years before. They are exactly the same as described by Mr. Divers in the previous Hardy Fruit Calendar. The reason that I did not refer to these practically imperishable labels in my [Calendarial notes for Dec. 25 is, that I was not aware of their being in commerce. "Horticultural Sundriesmen" would do well to obtain a supply of "letter and number-punches," and then to advertise them in the *Gardeners' Chronicle*. *H. W. Ward.*

THE NATIONAL CHRYSANTHEMUM SOCIETY.—As some strictures have recently been made in your columns in reference to the lack of encouragement given to the culture of the Chrysanthemum by the foregoing Society, permit me to give a few figures I submitted to the committee at its last meeting. The early Chrysanthemum show takes place on September 6, 7, and 8 next. At that exhibition the Society offers £15 7s. 6d. in money-prizes for early-flowering varieties, and the value of £6 13s. 6d. in Medals, this being their actual cost, exclusive of engraving, for all the Medals awarded by the Society are engraved at the cost of the Society before being handed over to the winners. There are in addition the Medals awarded to miscellaneous exhibits, probably representing another £8 or £9. The Directors of the Royal Aquarium give £50 in prizes for Dahlias and Gladioli, supplemented by £10 from the National Chrysanthemum Society. On October 11, 12, and 13, the Society offers in cash prizes for Chrysanthemums, £59 16s. 6d.; Medals (bare cost exclusive of engraving), £2. Some £8 to £10 worth of Medals will probably be awarded to miscellaneous exhibits. In addition, special prizes to the amount of £8 are offered for cut Carnations, and £40 for Onions and other vegetables. [What have these to do with Chrysanthemums?] On November 8, 9, and 10, the sum of £248 7s. is offered for cut blooms of Chrysanthemums; £87 5s. for plants, £12 16s. 6d. for table-decorations; fruit, £18; vegetables, £6 15s.; and Medals, £3. In addition, the Directors of the Royal Aquarium offer £30 as special commemoration prizes for cut blooms; there are other special prizes amounting to £12 6s.; and for vegetables, £53 5s. 6d. In addition there are the Challenge Trophy and Holmes' Memorial Cups, the Turner Memorial Cup, two other valuable Cups, and some articles of jewellery, representing as offered at the November Show, £461 15s. in cash, and £100 in value; to these may be added £15 in Medals for miscellaneous exhibits. On December 6, 7, and 8, open-class cut blooms, £37 5s.; plants, £23; and to amateurs for cut blooms, £9 15s. Add to this £8 in Medals for miscellaneous exhibits. The Society thus makes itself responsible for £673 12s. 6d. in cash and Medals, in addition to the Medals awarded to miscellaneous exhibits; and Cups, &c., to the value of £100. What conduces so much to the growth of membership of the Society is the fact that four exhibitions are held, in addition to many interesting meetings of the Floral Committee, covering, as I have before stated, "the whole of the Chrysanthemum season." Let me add, that every year witnesses additions made to the schedules of prizes, which annually grow both in bulk and value. *Richard Dean, Secretary.*

A HALL FOR HORTICULTURE.—Mr. M. Todd's communication obliges me to go over once more, the ground I have already covered in regard to this matter. If the conditions tending to success which prevailed in Edinburgh could be secured in London; if there was a Waverley Market adjoining a great

central railway station in the very heart of the Metropolis; if we had what I have ventured to describe as the "homogeneity" of Edinburgh; the support of the municipality; the co-operation of some leading citizens, and a practical monopoly of such an exhibition as that held in the Waverley Market, which is possessed by Edinburgh, then there might be a probability of making a big Chrysanthemum Show pay in London. I can deal with the subject with some degree of confidence, because, although I make myself liable to the charge of needless repetition, I know something of the long list of failures to attract the multitude to flower-shows in London during the past twenty-five or thirty years. The only exception apart from the November exhibition of the National Chrysanthemum Society (which is successful only because it is held at the Royal Aquarium, is the Temple Show of the Royal Horticultural Society, but then there are no money prizes offered, and only a limited value in plate and medals, while some expenses, otherwise necessary, are greatly minimised. And yet this great and attractive exhibition, held by the most renowned Horticultural Society of the day, in one of the most central and delightful spots in the City of London, and easily accessible, at which it is known the finest collections of Orchids and other plants will be seen; with the added patronage of Royalty, realises at the gates in three days only £1,262 14s. 8d., according to the recently published financial statement of the council—merely a small sum more than was taken at the Waverley Market in Edinburgh. Were the expenditure at the Temple Show on the same scale as that at Edinburgh, the financial gain would reach a vanishing point. Then there is the great Fruit Show held in September by the Royal Horticultural Society at the Crystal Palace, unique and instructive in a remarkable degree, and yet the Council have to admit in their annual reports that the "continuance of the show is absolutely dependent on at least £100 being raised by subscription each year towards a prize fund," in addition to the subsidy from the Crystal Palace Company. Let me again ask,—where are the great shows of the Royal Botanic Society and those formerly held at the Crystal Palace? They were abandoned because they did not pay. The Agricultural Hall has been suggested as an appropriate place for a Chrysanthemum show in November; a gloomy, barren, gigantic ice-house at that season of the year, repulsive in the extreme on a dull foggy November day, added to being difficult of access. The Royal Horticultural Society made a praiseworthy attempt in 1893, by holding a most attractive summer show there, and although assisted by a large subsidy from the Directors, could not make it pay; the financial loss to the Directors of the Hall must have been great. Even at Manchester, the Council of the Botanic and Horticultural Society have been driven to the necessity of speculating on the probable closing of the gardens at Old Trafford, the loss to the Society being considerable last year, though £600 less than in the previous year. The Society is discovering that it has to compete with the Belevue Gardens, and is driven to introduce outside shows. The York Floral Fête Committee have set apart for this year, prizes £650, £200 for music, £100 for fireworks, £150 for amusements, and £60 for balloons. These figures are significant. Is it to be wondered at, that those who have had a long and varied experience of London flower-shows, hesitate to embark on financial speculations in relation thereto of a decidedly hazardous character! Mr. Todd is quite correct in stating that "Mr. Dean as representing the Committee of the National Chrysanthemum Society, probably knows difficulties not apparent to outsiders," and all the optimistic prophecies and confident assertions made in your columns, and in those of other gardening papers, fail to draw me from a proper appreciation of these difficulties. They are, to my thinking insurmountable, owing to the manifest lack of public support of London flower-shows pure and simple. *Richard Dean, V.M.H., Ealing, W.* [This discussion must now be closed. Ed.]

VICTORIA MEDAL OF HONOUR.—It will be remembered that at the distribution of the medals at the Drill Hall, on October 26 last, the President of the Society, Sir Trevor Lawrence, in his opening speech, explaining the objects of the distinction, remarked that it would be very distasteful "if the honour were used for trade purposes." On Nov. 11 a circular, from which the following is an extract, was sent out by the Society:—"In awarding the Victoria Medal, the Council unanimously laid it down as a rule, from which no departure, under any circumstances, was permissible, that the distinction was to be entirely a personal one, and was not

to be used in any way whatever for the purposes of advertising." At the Council meeting on Dec. 14, the following resolution was passed, and has since been published in your own and other horticultural papers:—"In the event of any recipient violating the conditions on which the Victoria Medal of Honour was bestowed, by using it for advertising or for the promotion of trade interests in any other way, the name of such offender shall be struck off the list." In addition to this, the following announcement is made in the same journals for the week ending Jan. 15:—"The Council have been consulted as to a proper mode of the use of the Victoria Medal by members of the trade, having decided that the only permissible method is by the letters V.M.H. following the name of the holder of a Medal. No other mention of the Medal can be properly made in any publication pertaining to horticultural trade, or relating thereto." What steps, may I ask, have been taken to put into force the resolution passed by the Council on Nov. 11, and further qualified on Dec. 14? as it is a well-known fact that the honour was announced in trade circulars some time before Christmas. *F.R.H.S.* [Those V.M.H. who are not traders should take measures to prevent the degradation complained of, and induce the Council to take action. *Ed.*]

EARLY SWARMING OF BEES.—In the *Gardeners' Chronicle* for January 29, p. 76, I noticed an answer by "Expert" on inducing early swarms. He says, "Examine combs by driving the bees down with smoke;" and in another place he adds, "Give a pint of warm syrup once a week until the flowers begin to bloom." I must say that he is a little in error here. By disturbing hives at this time of year, you run the risk of the bees balling the queen, and by feeding them on syrup so early, you cause them to breed too fast; and when a cold spell comes, say, in March, the bees draw closer together, and leave the outer circle of brood to perish. If there is any doubt about the stores, slip on a cake of candy, with plenty of dry covering, but do not disturb the bees until a warm day in March. *Scotch Expert.*

BENGAL ROSE ABBÉ MIOLAN.—I am sending you a boxful of Roses, not knowing whether Roses are a plentiful commodity or not in England at this season of the year. [Oh, no!] I have quantities here, of the variety Abbé Miolan, a Noisette, as you will see. I have two beds of this variety in the flower garden, and have been enabled to gather blooms all the winter, gathering 100 every week for house decoration; but they do not stand well when cut, although in the beds they look well, and are continuous bloomers if planted in a sheltered position. Of course, the mild weather we are having suits them, as the flowers last longer when cut at this season than in summer. *P. C. M. G., Drunnals Gardens, Larne, Ireland.*

PEAR DUCHESSE D'ANGOULÊME.—The interesting problem which I sought to solve in asking the questions I did has elucidated at least one fact that I wanted, and which I actually anticipated in my suggestion as to the root-pruning having been done already in September, which is some six weeks before the usual time. The real interest centres in the question whether root-pruning done thus early, viz., in September, prompted as it was in this case by absence of fruit, can in any way be connected with a formation of additional flower-buds the same autumn, and not among those visible, as is now stated, on root-pruning. The actual presence of fruit-buds in September renders result of my inquiry somewhat vague on that score, and it would be interesting to learn what experience has been gained, and how early root-pruning has been so successfully accomplished elsewhere. It may be useful to remember in this connection that root-pruning carried out early in November would not show any results before the second autumn after the operation. Of course, the fact that fruit of remarkably good quality can be grown in this country is very satisfactory. I heard of the success at Bournemouth, but am unacquainted with details. If the methods adopted for such results in various districts can be formulated and be successfully applied to all good varieties of Pears, it would be the first step in the direction of ousting the foreigner from British markets. In this connection it may be remarked, that France sent us in 1896 about 250,000 bush. of Pears, and Belgium half that quantity; among which the former country supplied largely Duchesse d'Angoulême, Beurré Diel, and Louise Bonne; and the latter Beurré Hardy, &c., all of which we could grow at home, and probably without the expense of a wall, if only

well-sheltered plantations were made on high ground, out of the reach of spring frosts—a good reason for which is furnished by the fact of the thermometer with, for instance, +26° (=6° of frost) Fahr. on low levels (with possibly only +20° on grass), will simultaneously mark about +36°, or 10° higher at 100 to 200 feet altitude close in the rear, with an entire crop destroyed in the former, whereas complete immunity occurs in the latter case. The relative dampness of our climate is a convertible term for spring hoar frosts that kill the Pear blossom. Dew is heavy on grass and low herbage on low lands, and relatively absent on the higher grounds referred to; and the thermometer might fall to 32° even—nay, to 30°, and lower—without prejudice to the fruit-bloom, because there is little dew to convert into hoar-frost. If so, this double guarantee against risk from late frosts be added, the selection of a site sloping between S.S.E. and S.W., with natural or artificial shelter from E. and N.E. winds, that may yet ruin an early bloom, risk from frost seems to cease to play a part in our Pear-economy. The Continent of Europe being less humid than our Isles, risk of frost is lessened. Mr. Ward's belief that Pears from walls are invariably superior to those grown in the open must not be accepted literally. I certainly prefer all early Pears grown in the open, and some of the later ones are at least equally good in the South of England. Where Mr. Ward dissents from my statements, in another case he only quotes half the sentence, omitting, for instance, "as grown in this country," where I disparage this variety as here grown, adding about the splendid examples sent us annually from France. I think this Pear is delicious as sent us from France in September in tons for many years past; and yet we can, apparently, grow it at home of equal good quality. It will be interesting to learn towards next autumn what crops were gathered from the various trees treated, as we are told, similarly in that quarter. The result may be an excellent lesson for all growers. The agricultural returns for 1897 to hand since writing the foregoing show the total importation of Pears to have been 1,050,000 bushels against rather under 500,000 bushels in 1896, and about 400,000 bushels in 1895. These figures accentuate the foregoing remarks. *H. H. R., Forest Hill.*

THE MILD WINTER, CO. CORK, 1897-98.—This is a most extraordinary season. The following March-flowering Daffodils have been for more than a week in bloom: Androcles, Countess of Annesley, Early Bird, this latter since Jan. 17; North Star, Saragossa, Ard Righ (very fine), of which I send specimen; Cervantes Pallidus præcox, Golden Spur, Henry Irving, the common double Daffodils are a sheet of bloom, and many others. Then as to spring flowers, Snowdrops, Crocuses, Chionodoxa sardensis, Polyanthus of all sorts, Primroses, Omphalodes verna, flowering Currants, Azara microphylla, three sorts of Laurustine, Sparmannia africana, Mahonia japonica, Pyrus japonica, Jasminum nudiflorum. The neighbours Bees are crowding round the bloom of Prunus Pissardi, drinking up their sweet juices. In a sheltered spot Veronica Traversii, Potato stalks in bud, and Lenten Roses are a mass of bloom. During my more than sixty years of life, I do not remember such a season, and for fifteen years' record with Daffodils, no registry like this season of 1897-98. *W. Baylor Hartland, Ard Cairn, Cork.*

CONTINUOUS FLOWERING OF PANCRATIUMS.—As a grower of, among other things, Pancratium blooms for market, I think it may interest some of your readers to know that my Pancratiums have this morning (February 1) completed an unusual if not altogether unprecedented period of flowering. On February 1 of last year I cut my first bloom of the season, and have continued to cut them every morning for 366 days. Those blooms opened on Sundays were cut and kept for Monday's market. I consider it all the more remarkable as all of the plants are grown in one house, viz., a Eucharis-house, consequently there is no bringing batches forward. The plants are still throwing up fresh flower-spikes. *Henry Porter, Barkfield Nursery, Freshfield, Liverpool.*

ROYAL BOTANIC GARDENS, CEYLON.—The first three "Circulars" published have reference to the Cacao-canker, which is supposed to be due to the attacks of a root-fungus. Preventative treatment is all that can be afforded; indeed, at present but little seems to be known of the fungus.

SOCIETIES.

RICHMOND ALLOTMENTS ASSOCIATION.

JANUARY 4. — The annual meeting of the Richmond Allotments Association took place on Friday evening at Queensbury Chambers, Richmond, the President, Mr. F. W. DUNBLEBY, J.P., being in the chair. The report of the Association stated that there had been an increase in membership during the year. The prizefund did not come up to the expectations based upon the experience of former years, but this was attributed to the many calls made by the Jubilee. It necessitated reducing the number of prizes at the annual exhibition.

The support received from the Richmond Town Council and the Richmond Athletic Association, and the kindness of the Manager of the Association Ground were acknowledged. The accounts showed that the balance of 18s. 1d. with which the year commenced had been extended to £2 15s. 1d. Mr. F. W. Dunbleby, J.P., was re-elected President, Mr. Nevard Hon Treasurer, and Mr. Rogers as Hon. Sec.

EDINBURGH FIELD NATURALISTS' AND MICROSCOPICAL.

JANUARY 26.—At a meeting of this Society on the above date some notes on "The Natural History of the New Hebrides Islands" were communicated by the Rev. J. H. LAWRIE, one of the members, who was for many years a missionary on Aneityum.

In referring to the vegetable productions of the islands, Mr. Lawrie said that the staple food of the natives is Taro (*Caladium esculentum*), and Yam (*Dioscorea sativa*), the former grown on the swamps, and the latter on the dry volcanic districts. As food, these are looked upon by the natives in the same way as we do Potatoes, flour, or meal. Bananas and Sugar-cane are also much cultivated. Coffee, Oranges, and Pine-apples have been introduced, and it has been found that whatever thrives in the West Indies may be cultivated with profit in the New Hebrides. Copra, or the dried kernel of the Cocoa-nut, is largely exported for manufacture of soap, pomades, and other useful articles. The natives do not regard arrow-root as a food: but being of the finest quality, it is manufactured and sold for payment of their bibles and churches. Kava, an intoxicating beverage, obtained from the root of *Macropiper methysticum*, is a necessary accompaniment of all the native orgies. One of the most useful trees is the Pandanus, or Screw Pine, the leaves of which are made into dresses for the women, wrapping bands for the men, sorcerers' bags, food-baskets, sleeping-mats, and canoe-sails. The war-clubs and bows are made from species of *Casuarina* and *Acacia*. The principal food-bearing trees indigenous to the islands are the Cocoa-nut (*Cocos nucifera*), the Bread-fruit (*Artocarpus incisa*), Rose-apple (*Eugenia pimenta*), and Papaw-apple (*Carica papaya*). Crotons, Dracenas, Hibiscus, and other ornamental plants grow luxuriantly. Among Cryptogams, 126 species of magnificent Ferns have been found on Aneityum alone.

THE SCOTTISH HORTICULTURAL ASSOCIATION.

FEBRUARY 1.—The monthly meeting of this Society was held on the 1st inst., at 5, St. Andrew Square, Edinburgh, and the chief attraction of the evening was the lecture by Mr. Jones, of Lewisham, on "Chrysanthemums and their Culture."

The Chairman, Mr. Dodd, who is always happy in his choice of phrases, exactly expressed the feeling of the meeting when, in introducing Mr. Jones, he said, that to think of the Chrysanthemum was to think of Mr. Jones, who, perhaps more than anyone living, had done most to popularise and improve the cultivation of those beautiful flowers.

The preliminary business consisted in passing the minutes of the annual meeting, which showed the Society to be in a most prosperous condition, and in the reception of twelve new members. The exhibits on the table consisted of a choice glass of Daffodils and Narcissus, fringed with *Acacia dealbata*, shown by the President; and some very chaste wreaths of *Clematis indivisa*, by a member of the Association.

BEES IN A BLOCK OF STONE.—A correspondent writes us to insert the following cutting from his local paper as being of interest to bee-keepers. During the progress of work upon a new church, which is being erected by Mr. E. C. Jordan, at Crindan, Newport, a remarkable discovery was made. The masons were sawing through a piece of Bath-stone from Corsham quarries, near Bath, when they came upon a small cavity lined with spar. Such cavities are not unusual, but the surprise of the workmen can naturally be imagined when it was found that inside were six bees. Apparently (the sections

were brought to the *Newport Argus* Office for inspection) there was no entrance to the cavity before the saw cut into it, and the presence of the bees is a mystery. They were alive, and two of them were still quite active when brought to the *Argus* Office in a small box by Mr. Page, architect, who is in charge of the works for Messrs. Graham, Hitchcox & Co. He was on the spot when the discovery was made, and he at once captured the bees, and secured the block of stone as a curiosity. The question is, how did the bees get there? *Bee Journal*.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named: and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts—6, Scotland, W. 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

BOOKS: L. C. Mr. A. D. Webster's *Hardy Ornamental Flowering Trees and Shrubs*; published at the office of the *Gardening World*, 1, Clement's Inn, W.C.—B. P. You might perhaps obtain *Botany for Beginners* at one or other of the second-hand bookstalls. With this and Darwin's *Elements of Botany*, published by the Cambridge University Press in 1895, you will have good elementary information on Systematic and Structural Botany. Five years horticultural experience is necessary before entering Kew, but no definite botanical knowledge, which may, however, be easily acquired whilst at Kew. Application should be made to the Curator. See our issue for the 22nd ult., p. 56.

BOTANICAL NAMES: C. Goulter. *Faya* (or *Myrica*) *fragifera*, Canary island Wax-tree; *Sicyosperma gracile* (*Cucurbitaceae*), annual climber from Mexico; *Echinocystis lobata* also a climber, of the same Nat. Order as the last; and *Paspalum elegans* synonymous with *P. tenellum* or *P. membranaceum*, an ornamental grass, are good names.

CORRECTION.—We are requested by the publisher to say that in the advt. of "Izoline," p. vii., in last issue, instead of Feb. 9, 1892, read Feb. 12, 1898.

CRICKETS IN THE GLASS-HOUSES: W. J. S. Enquire of the horticultural sundriesmen—they sell traps and other means of destroying these pests; or dig out a hole in the floor of each of your glass-houses and sink a cloche or big bell-glass, or a 12-inch flower pot bottom uppermost, leaving the holes or hole uncovered and putting some odorous fruit inside, and you will trap thousands.

CUCUMBER ROOTS: W. G. The plants are affected with eelworms, for which there is no known cure. Please send specimens of the insects you have found in the soil, and we will endeavour to identify them.

DUNBAR REGENT POTATO-SETS FOR PLANTING: X. Y. Z. This variety, owing to its liability to take the disease, is going out of cultivation, in favour of the Bruce, Jeanie Deans, Lady Fife, and others, which enjoy comparative immunity from attack. You might learn from Mr. A. Findlay, Markinch, Fife, where sets can be obtained.

FRUIT-TREES FOR A FENCE WITH A DUE SOUTH ASPECT IN ESSEX, &c.: *Amateur*. Pears—Beurré Rance, Easter Beurré, Van Mon's Léon Le Clerc. If you would like an early variety, plant Doyenné du Comice or Bon Chrétien. The aspect is too warm for most varieties of Apples, but you might plant Newtown Pippin, Reinette du Canada, and Washington, which are excellent, but sometimes do not ripen thoroughly in this country away from a wall. Of Plums, plant Reine Claude de Bavay and Reine Claude Violette, both of the Gage type, and very good eating; the others might be Jefferson, Coe's Golden Drop, and Late Transparent; plant forthwith on free stocks. The Pears and Apples should be trained horizontally, and the Plums fan-shaped. Cherry-trees may be transplanted at this season.

LEAFING OF THE OAK: *An Old Colonist*. In an article entitled "Indications of Spring," published in these columns on April 7, 1888, and embodying the observations of Robert Masham, Esq., of Stratton in Norfolk, extending over sixty years in the case of some of them, we find that in the interval of fifty-four years the Oak at that place was earliest in leaf on March 31, 1750; and latest on May 20, 1799, a difference of fifty days. The medium date was April 26, 1757. R. Masham, who was a F.R.S., died in 1797, aged ninety years.

LILIU BAKERI, ETC.: D. G. 1, L. Maximowiczii var. Bakeri, Elwes; 2, L. Bakerianum, Collett and Hemsley; 3, L. Bakeri, Purdy, are three different plants. 1, is a Japanese Martagon with bright scarlet flowers—it is figured and described in the great monograph of Elwes; No. 2, comes from Upper Burma, and is allied to the Bermuda Lily, with large funnel-shaped white flowers. It is figured in the *Journ. Linn. Soc.*, vol. xxviii. No. 3, is described in *Erythraea* for Oct. 1897, p. 104. It is a scarlet Martagon nearly allied to L. columbianum, inhabiting Washington territory and British Columbia. All three are in cultivation. J. G. B.

MANURE FOR MAIDENHAIR FERN IN SMALL POTS IN A SITTING-ROOM: E. N. W. Ferns dislike manure, and it is only advisable to afford it in the growing season, and in very mild doses. A bushel or two of spent Mushroom-bed manure, and 1-yr. old tree-leaves may be put into a tub containing about 40 gallons of rain-water, and in about a week afterwards it will make a liquid-manure that answers very well if diluted with rain-water. The dung may be left out if the odour is found to be too strong. Some very robust species of Ferns may be afforded cow-dung and soot-water, taking the precaution to use it in a clear state, otherwise the soil will be closed to the air; but this would be scarcely allowed in a sitting-room, unless the manure-water is allowed to drain away from the pots out of doors. Nitrate of soda in minute doses sprinkled on the soil once a fortnight would do good. A thimbleful to a 6-inch pot is enough to use at one time; first affording the Ferns sufficient clear water to wet the ball throughout, and then affording a slight second application of water in order to carry the nitrate or some of it to the roots.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—J. L. Send when in flower.—H. W. 1, *Elaeagnus macrophyllus*; 2, *Elaeagnus pungens variegatus*; 3, *Euonymus*

japonicus var.—J. W. K. *Trachystemon orientale*, a plant nearly allied to Borage; it has been called Nordmannia, Psilostemon, and Borago. The name we give you is that adopted in the standard *Index Kewensis*.—*Alphus*. *Lycium sinense*, *Saxifraga longifolia*, so far as we can tell without flowers.—G. R. The flower sent is of a very pretty variety of *Cattleya Trianaei*; the rich orange in the throat is peculiar.—R. G. R., *Limehouse*. 1, *Pholidota imbricata*. The other two are varieties of *Dendrobium undulatum*.—L. O. An *Eria*, but which species it is impossible to say from the specimen sent.—F. G. *Cypripedium vernixium*.—J. W. *Fuchsia triphylla*.

ON A WALL FACING SOUTH-WEST *Amateur*. For growing on the wall, house open to the sun from south-west, you might plant Pears Jargonelle, Marie Louise, Winter Nelis, Marie Benoist, and Glou Morceau, all excellent varieties; in succession from August to January.

ORCHID INJURED: F. K. We believe that the mischief arose from the emanations from the wood used in the staging. The plant has every appearance of having been injured by poisonous fumes.

PATENT ARTICLE: R. G. Jarrett. See answer to "Seed-Drill."

PLANTS FOR PLANTING ON THE SANDY BANKS OF A BRACKISH STREAM: *Banks*. *Tamarix germanica*, *Salix* in variety, *Alnus* in variety, *Lycium barbarum*, *Hippophae rhamnoides*, *Atriplex Halimus*.

SEED-DRILL, ETC.: G. A. You should make application at the Patent Office (on any day from 10 to 4), 25, Southampton Buildings, W.C., bringing the specification of the invention, and you will then be enabled to ascertain if a tool similar to the one you desire to obtain a patent for has been so protected.

SHALLOW FRAMES AND FOUNDATION COMB: M. T., J. O. W. 1. Will shallow frames that were used last year do again?—Yes, but they must be properly cleaned. A good plan is to boil them well in soda-water for twenty minutes. No frames that are very dirty and old should be used again; it is much better to burn them and buy new ones, seeing they are so cheap now. 2. Will the same foundation that is used for brood standard frames do for the shallow frames, or that which is used for the sections?—The same foundation should be used for shallow frames as is used for brood frames, but secure it a little thinner, if possible. Section comb will not do for either shallow or brood frames; being so very thin, it would not stand the extractor, and even if it did, you would get a large waste in honey, and break the combs so much that they would be useless for returning to the hive.

SHRUB TO GROW IN A TUB IN AN OUT-OF-DOOR AVIARY, ALSO FLEX: E. N. W. *Colletia cruciata*, *Quercus Ilex*, Irish Yew *Thuja sibirica*, Virginian Red Cedar, or Sweet Bay. The birds are less likely to peck the leaves and buds of these plants than *Euonymus* and the *Rhododendron*. You might give a trial to the common and crested forms of Hart's-tongue Fern, *Scolopendrium*; Wallrue, *Ruta-muraria*, forms of *Blechnum spicant*; but we fear that no Fern will be safe from depredation. We do not suppose the birds would touch a Metake Bamboo plant.

SPRING PROPAGATION OF LAVENDER: G. M. Take slips, if possible, with roots, in March and April, and plant these in rows 1½ to 2 feet apart, and 1 foot apart in the rows, and afford water till the plants are established. The plant does best in a light warm soil.

STRAWBERRY CULTURE: *Smith*. You will find articles giving the chemical constituents of Strawberry plants, and suggestions as to the best means of supplying these in the form of manure, in the *Gardeners' Chronicle*, October 24, 1896, p. 489, and November 14, 1896, p. 590.

VINE: A. G. The Vine having lost all of its roots owing to the stagnation of water in the soil, had better be rooted out, recovery being well nigh impossible, and the wood sent shows it to be so.

SATURDAY, FEBRUARY 12, 1898.

NOTES FROM A LITTLE CORNISH GARDEN.

(Continued from p. 33.)

JANUARY.—Owing to the exposed situation of my garden, I am apt to receive some stern disappointments at this season. Last month, by means of a deceitful blandness, numerous leaves were induced to start from their buds, and many flowers to show their inexperienced faces. But these rash firstlings were “no sooner blown but blasted” by the resistless hurricane:—

“The young green leaflet’s harrier, sworn
To strew the garden, strip the shaws,
And show our spring with banner torn.”

However, several flowers have managed to retain a healthy appearance, chief among these being the Primroses, both wild and tame. It seems to me that none of the garden Primroses approach the yellow one in beauty and delicacy of colouring. Herrick, in his persistent search for floral similes to the various conditions of his “virgins,” treats the Primrose unfairly in comparing its colour to that of the skin of those suffering from chlorosis:—

“Virgins, time past, known were these,
Troubled with green sicknesses;
Turned to flowers, still the hue,
Sickly girls, they bear of you.”

The yellow of the Primrose is utterly removed from any suggestion of sickness or disease. On the contrary, it is pre-eminently one of the “fresh” colours; it goes with clean print dresses, sweet milk, ruddy cheeks, and “ideal” country simplicity—a very different thing, it may be remarked, from any real rural product. The Primrose’s scent is like its colour, delicate and fresh. No words can approach a description of these qualities of scent and colour. May we fancy that some beautiful fairy, having feasted on rose-petals, sweet wild herbs, and the south-west wind, breathed her fragrant breath on the lovely Primrose blossom?

Primroses are among the easiest of all plants to grow. They do best in the shade of deciduous trees, and I find them satisfied under these conditions with the poorest and driest of soils. Judging from their leaves, one would, of course, expect them to stand a dry situation well. The leaves are corrugated, hairy, and thick, unlike those of such plants as *Pulmonaria officinalis*, *Cyclamen*, and *Hepatica triloba*, which are natives of damp, shady places, and have to get rid of a large quantity of moisture under adverse conditions. These latter, therefore, have mostly large thin-leaf surfaces, naked of hairs, and often have their leaves mottled owing to the spongy parenchyma being more open-woven in some places in order to allow water to pass off readily. The Primrose almost partakes of the character of a bulbous plant. Its thick starchy root contains as good a store of last

year’s solar energy as does bulb of *Snowdrop* or *Crocus*. Hence its earliness in showing leaves and flowers which it could never have produced by the aid of this year’s sun alone.

Since Christmas day my winter Aconites have been sending up experimental blooms, but I do not anticipate any considerable floral effect from them for another fortnight or more. I like to watch the daily lengthening for eight days of the yellow dome, one of whose functions is to protect the ripe pollen from rain. As the short outer row of stamens first ripens, the short sepals suffice for its protection, but day after day a longer and more central row ripens and requires protection, and each day the sepals grow longer to meet the new need. In spite of the pretty little nectaries, I do not think many bees will visit them at present. As most of the early spring flowers are produced from last year’s reserve store of nutriment, they commonly appear before the leaves are well developed. They spend last year’s savings, and are able to cut a fine figure before most plants have begun even to accumulate the wherewithal to produce flowers.

The winter Aconites will give my first mass of colour in the New Year. I like a garden which has always some brilliant display in evidence, as well as containing interesting and beautiful single plants. I am looking forward to the following “blazes” in my garden with considerable interest: Winter Aconites, yellow Primroses (under a row of trees), Crocuses, Tulips, Anemones, Wallflowers, *Escholtzias*, *Silene* (carpeting my Rose-bed), Poppies, and Sweet Peas.

I am continually receiving severe criticisms of my gardening when I walk in the country. The hedges and meadows, hillsides, and even ditches, make constant rude remarks, and invite me to look at them and learn. I endeavour to take their advice. If we are to have any originality in our gardens, we must study natural plant effects—not necessarily to copy them. It is not, of course, true that everything which Nature produces is pleasant to the cultivated taste, for Nature has a good many other prejudices to consult besides those peculiar to man. The dung-beetle’s view of beauty, for instance, must not be forgotten. Then it is that the gardener should study Nature constantly and closely, but should remain slightly critical and selective. The last thing the hedges told me was, that I had no business to have so much bare earth showing in my garden in January. My Saxifrages are growing into nice clumps, it is true, and my Wallflowers present me with a very nice shade of green; my Periwinkles cover a little stony-bank with glossy leaves, and show a number of early blue flowers with the most remarkable of pistils; my little clumps of *Cyclamen* are a mass of marbled foliage; and little green points proceeding from various buried bulbs dot the ground at frequent intervals. All this is true, yet the hedge’s criticism retains its force, so I have written off for a selection of dwarf evergreen plants, *Veronicas*, *Ericas*, *Kalmias*, and the like, as well as a few more varieties of *Polystichum* and *Polypody* Ferns than those I already have.

The Christmas Roses are still, of course, in their glory, and remain the one flower which seems really happy out-of-doors at present. Still, the gardener’s mind must now be chiefly anticipant; eager for effects to come, rather than having any very great grounds for joyfulness in the present display afforded by his garden. Now, one may study books and catalogues by the light of the lamp and the fire’s warmth, and the genuine gardener will find that his hobby often helps his reading, as his reading most certainly helps his capacity for extracting pleasure from his garden. For I hold that the most fortunate gardener is he who is a bit of a botanist, a bit of an artist, a humanist, and a lover of earth-digging. One other thing is necessary to the fortune of the gardener, and that is a moderate-sized garden in which he may ply his craft. *Harry Roberts.*

WILLIAM CATTLEY.

VERY little is generally known of the man after whom Lindley named one of the most magnificent of the genera of Orchids. Lindley himself (*Collectanea Botanica*, 1821, plate 33), says in reference to the dedication:—“Our drawing was made by Mr. Curtis from a specimen which flowered in Mr. Cattley’s stove last November. Without exception, it is the handsomest species [*C. labiata*] of the order we have ever seen alive, and we have on that account the greater pleasure in publishing it, as it has given us an opportunity of paying a compliment to a gentleman whose ardour in the collection, and whose unrivalled success in the cultivation of the difficult tribe to which it belongs, have long since given him the strongest claims to such a distinction.” In Nicholson’s *Dictionary of Gardening*, Cattley is described as a “famous patron of botany, and one of the most ardent collectors of rare plants of his day.” In Johnson’s *Gardeners’ Dictionary*, he is designated, “a magnificent patron of botany;” but the name of Cattley does not appear in Britten and Boulger’s *Biographical Index*, and I understand he is not to be included in the forthcoming supplement to that most useful work, though his claims to a place are, in my opinion, equal to those of many others. Possibly, however, this note may induce the compilers to change their minds.

Cattley’s garden was at Barnet, and he must have had a very fine collection of plants, for besides the Cattleya, the following plants figured in the *Collectanea* were from his garden: *Vanda teretifolia*, *Oxyanthus speciosus*, *Psidium Cattleianum*,* *Metrosideros vera*, *Cephaelis calycina*, *Puschkinia scilloides*, *Ornithogalum fimbriatum*, *Cypripedium insigne*, *Vanda multiflora*, and *Sarcanthus rostratus*. These were out of a total of forty plates. I have not found any biographical sketch of Cattley, though it is probable one exists in the *Gentleman’s Magazine*. There is no doubt, however, that he was intimately associated with Lindley in some of his other early works, and that he had a large collection of drawings of plants. Lindley’s *Digitalium Monographia* (1821) was illustrated by Ferdinand Bauer, “penes Gulielmus Cattley.” This work is dedicated to Cattley in the following terms:—

“Viro generoso Gulielmo Cattley, armigero, Societ. Linn. Lond. et Hort. Sodal., Botanices Scientiæ callentissimo, Patrono Nulli secundo, et, quod maximi ducit, amico suo optimo, D.D.D. Auctor.”

Lindley was not a man who used complimentary language of a fulsome character, and I think we may assume that Cattley, although no great contributor to botanical literature, was more than an amateur gardener. There is at least one other botanical work with which Cattley’s name is associated. It is generally known as Braam’s *Icones Plantarum*. The full title is *Icones Plantarum Sponte in China nascentium, e Bibliotheca Braamiana excerptæ*. London, 1821. An editorial note runs thus:—“*Icones Plantarum e quibus tabulæ sequentes excerptæ sunt, olim in China celeberrimo Van Braam summâ curâ collectæ, nunc in bibliotheca artium fautoris eximii Gulielmi Cattley armigeri reponuntur.*” There is also a second copy of this work in the Kew Library, dated London, 1818, and having a lithographed title page, “*Icones Pictæ Indo-Asiaticæ Plantarum excerptæ e codicibus Dom. Cattley.*” Following the title-page is an “advertisement” signed by Cattley. There is no other letter-press, and the plants, which are mostly now familiar, are unnamed. Among them are *Dicentra spectabilis* and *Rosa Banksiæ*. Should I succeed in finding anything more definite concerning this work I shall publish it, together with a full list of the plants figured. Mr. B. Daydon Jackson has kindly looked up the Linnean Society’s records, from which we learn that Cattley was elected a Fellow in January, 1821, and reported dead May 24, 1842. *W. Botting Hemsley.*

* Cattley had previously contributed a note on this plant to the *Transactions* (iv. p. 315, pl. 11) of the Horticultural Society of London, where also there is an excellent coloured figure of the plant.

NEW OR NOTEWORTHY PLANTS.

KÆMPFERIA ETHELÆ (*J. Medley Wood, n. sp.*)*

I SEND by same post a pencil sketch reduced, a coloured drawing natural size, and description of a new species of *Kæmpferia*, which has flowered in these gardens (fig. 34). The original plant was brought from the vicinity of Massikessi by Mr. Reuben Benningfield, and the plant was given to us by Mr. Jas. Benningfield, in honour of whose wife I have named it.

So far as I am aware, it is very much the most showy of the genus, and will well repay cultivation. The flowers are produced in the early spring, while the leaves are not fully grown, and therefore are very conspicuous. The coloured drawing of the flower is exactly natural size, but I regret that it does not fully represent the beauty of the flower, and only gives an idea of what it really is. I have called it peach, but in drying the flower, the blue in it is very conspicuous, and probably the colour would be better described as light purple. The root-stock is tuberous, irregular in shape, and with a strong aromatic odour. Stem leafy, at the time of flowering 6 to 8 inches high, afterwards lengthening to 2 to 3 feet; leaves oblong-lanceolate, clasping the stems by their long sheaths, the blade of the uppermost ones 10 to 14 inches long, lower much shorter, 2 to 2½ inches wide in the central portion, mid-vein stout, lateral very oblique; flowers solitary, radical; calyx tubular, splitting in front half-way down; corolla hyaline, white, three-parted; segments linear-oblong, acute, with central vein, and four to five lateral ones on each side, 2 to 2½ inches long, 6 to 8 lines wide in central portion; staminode unequal, three-lobed, lower lobe ovate, bilobed for two-thirds of its length, and strongly recurved, 2½ to 3 inches long, 2½ to 3 inches wide, lateral ones oblong, erect, peach-coloured, darker at outer edge, and becoming lighter towards centre of flower; labellum with a broad yellow crest, which reaches nearly half-way down the tube; stamen one, anther two-celled, a little curved, filament widened and thickened, connective produced into an oblong petaloid lamina, which is a little contracted in the upper portion, and lacerate at apex, 2 to 2½ inches long, 5 lines wide; ovary three-celled, many-ovuled.

STERNBERGIA MACRANTHA (FIG. 35).

Sternbergia lutea, already well-known in gardens, is a very fine plant, which flowers freely in the open ground from October till January; and *Sternbergia macrantha* is a still better species, the flowers of which are of a bright yellow colour, and twice the size of those. This species was introduced into commerce by Mr. Siehe, at Mersina, who found it in the Cilician Taurus. *U. D.*

KEW NOTES.

JASMINUM NUDIFLORUM.—No colour, it seems to me, is so effective during our dull, sunless, midwinter days as a bright and glowing yellow, and no plant provides it better than does this *Jessamine*. We have a specimen planted against a south-west wall, and covering some 12 square yards of space, which has been in flower more or less since November, but is just now at its very best—every one of its myriad branches a graceful, pendent wreath of blossom. Even in the open, away from a wall or other protection, and merely a sprawling shrub, it is very pretty. It was one of Robert Fortune's introductions from China.

* *Kæmpferia Ethelæ*, n. sp.—Radix tuberosa, aromatica; folia oblongo-lanceolata, amplexicaulia, laminæ superiores, 10–14 poll. longæ, inferiores multo breviores, 2–2½ poll. latæ in media parte, vena media robusta, lateralibus venis obliquissimis; flores solitarii radicales; calyx tubulosus antice diffidens; corolla alba, hyalina, 3-partita, segmentis lineari-oblongis, acutis, cum vena media et 4–5 venis lateralibus utraque in parte, 2–2½ lin. longis, 6–8 lin. latis, in parte media; staminodiu ovato, trilobato, recurvato, lobis lateralibus oblongis, erectis, pallide roseo-purpureis, cum lata crista lutea; lobi antheræ paullo curvatæ, connectivo producto cum lamina oblonga petaloidea, paullo constricta, in parte superiore, et lacerata apice, 2–2½ poll. longa, 5 lin. lata.

THE MEZEREON.

There is an autumn-flowering variety of *Daphne Mezereum* called *grandiflora*, or *autumnalis*, which is in flower by October, and keeps on up to the present time. But the typical plant generally flowers about the end of February, and on through March, although many of our plants are already in full bloom. The white variety (*alba*) does not seem to be so forward as the red-purple type. The *Mezereum* is alike desirable for the beauty of its flowers, and for their delightful fragrance, yet it is by no means plentifully represented in gardens. This, probably, is due, in a great measure, to neglect in keeping up a succession of young plants, which it is necessary to do on account of the comparatively short-lived nature of the shrub and its propensity to decline in vigour after once reaching its full size. It grows wild in several parts of Britain, but is not believed to be a true native.

CHIMONANTHUS FRAGRANS.

It is scarcely necessary at this date to enlarge on the merits of this shrub. For 100 years, at least (it was introduced from Japan in 1776), it has held a high place in the esteem of gardeners. On old garden walls in long-established places especially, fine specimens may be seen. There is one at Glasnevin, which Mr. Moore sends word is magnificent this year. Its chief recommendation, of course, is the delightful fragrance of its blossoms, which in colour are dull yellow, purplish in the centre. They commence to open before Christmas, and continue until March. Although hardy in the open near London, it ought always to be given a place on a wall. Of several varieties, Lindley's *grandiflorus* is the best. *W. J. B.*

PROTEA CYNAROIDES.

There are two large specimens of this, the noblest of all the *Proteas*, in the Succulent-house at Kew, and it is rarely that one or the other of them is without flowers. Several fine blooms will be open in a few days, and as they remain fresh on the plant for two or three months, they will be a lasting attraction (see *Gardeners' Chronicle*, 1895, i., 773). It is evident from the behaviour of these two plants since they were planted in the gravelly-bed among the *Agaves*, that this *Protea*, at any rate, is easily managed when planted in well-drained soil in a sunny greenhouse. The tallest stems are 10 feet high, and they are handsome in their rich green spoon-shaped leaves, apart from the attractions of their enormous flower-heads, which, as the name indicates, are not unlike the head of the Globe Artichoke; they are, however, much handsomer, being cupped, and the bracts are of a bright rose-pink colour. *W. W.*

ORCHID NOTES AND GLEANINGS.

CATTLEYA HARDYANA × VAR. FANYAUIANA.

MR. FANYAU's variety of this fine species is remarkable for its fine coloration, especially of the lip, which is of a rich maroon with a large yellow blotch on each side near the base, and numerous streaks of golden colour. *Lindenia*, t. DXXIII.

ODONTOGLOSSUM BIOTONENSE.

Lindley var. *album*, *Lindenia*, t. DXXIV.

CYPRIPEDIUM INSIGNE VAR. JANUS, *L. Linden*.

The remarkable feature about this variety is the lower sepal, which is pure white, but destitute of spots. *Lindenia*, t. DXXV.

CATASETUM SPLENDENS × VAR. GRIGNANI, flower white, sepals and petals white tipped with carmine, and with spots of same colour at the base. *Lindenia*, t. DXXVI.

LÆLIO-CATTLEYA RIDOLFIANA × VAR. ARMAIN-VILLIERENSIS.

This fine hybrid will necessitate the preparation of longer labels than have hitherto sufficed. It is a hybrid between *Lælia purpurata* and *Cattleya Mossiæ*, differing from either of the other forms having a similar parentage. *Lindenia*, t. DXXVII.

CATTLEYA AUREA.

A double plate of the *Lindenia*, t. DXXVIII-DXXIX, is

devoted to the illustration of varieties of this splendid species.

CYPRIPEDIUM BEECKMANNI × L. LINDEN.

A cross between *C. Boxalli* and an alleged *C. bellatulum*, see *Gardeners' Chronicle*, xxii., pp. 238, 446. The plant, we may mention incidentally, was sold for £160, = 4,000 frs. *Lindenia*, t. DO.

CYPRIPEDIUM INSIGNE CITRINUM.

Although none of the yellow forms of *Cypripedium insigne* which has yet appeared is equal to the famed *C. i. Sanderæ*, yet they are all pretty and interesting as showing the various stages by which that highest example of colour suppression in the species has been attained. In *C. i. citrinum* we have a flower of good form, and of a clear light yellow colour, with the upper third of the dorsal sepal pure white. The yellow portion of the dorsal sepal shows indistinct brown spots, and the white portion some very pale purple ones, so that the suppression of colour as in *C. i. Sanderæ*, and in a less degree in *C. i. Sanderianum*, and others, is not so effectually accomplished in *C. i. citrinum*.

A specimen of it was shown at the Royal Horticultural Society, by Capt. Holford in his fine collection of *Cypripediums*, in January; and a twin-flowered inflorescence, which has been in bloom for a considerable time, is sent by W. M. Appleton, Esq., Tyn-y-Coed, Weston-super-Mare.

LÆLIA ANCEPS.

A plant of what was generally admitted to be the finest white *Lælia anceps* which has yet appeared made its appearance at the Auction Rooms of Messrs. Protheroe & Morris on Friday, February 4. It may be likened to *L. a. Schroderiana*, whose chief characteristic is the unusually large and flat front lobe to the labellum. The variety in question had very large pure white flowers, the sepals and petals of which were very broad, and the whole flower of fine form and substance. The labellum, however, was the most extraordinary feature, on account of its great size, and the extraordinary development of the front lobe of the lip, which appeared to exceed in length the basal portion. The side lobes of the lip had some purple lines, and the crest a yellow tinge. At fourteen and a half guineas it was acquired by H. T. Pitt, Esq., Rosslyn, Stamford Hill, a great fancier of unusually good Orchids.

AN ABNORMAL CATTLEYA TRIANÆI PLUMOSA.

The pretty variety of *Cattleya Trianæi* known in some gardens as "plumosa," and having a finely formed flower, richly coloured labellum, and purple feather on the petals similar to *C. T. Backhouseiana* is always a pleasing object, but the flower of it sent by Walter C. Walker, Esq., Percy Lodge, Winchmore Hill (gr., Mr. Geo. Cragg), presents it in a new but not less beautiful form. The pale lavender sepals, and the broad and slightly darker petals with their showy purple feather are formed and arranged as usual; but there are three labellums, each perfect though slightly narrower than the normal labellum would be. Two of the lips are arranged side by side, the inner edge of each being under the column (of which there is but one); the third lip is below the other two, and effectively arranged with the others, each lip having the colours as in a perfect specimen. *J. O. B.*

SANDRINGHAM HOUSE.

THE disposition of the trees in the park and pleasure-grounds—whether by accident or design, or by both—is most effective and picturesque. Oaks of enormous dimensions and unknown age are dotted all over the noble demesne. The memorial trees, which have a special value to arboriculturists, from the fact that they are mostly named and dated, and that, consequently, their rate of growth can be gauged, are subjoined:—*Araucaria imbricata*, planted by the Countess Valerie Hohenthal, November 9, 1863; 2 feet girth. *Abies Pinsapo*, planted by H.R.H. the Hereditary Grand Duke of Mecklenburg-Strelitz, April 4, 1874; 4 feet girth. *Pseudo-tsuga Douglasii*, planted by Lady Adelaide Talbot, April 20, 1866; 6 feet girth. *Abies nobilis*, planted by Lady Gertrude Talbot, April 20, 1866; 3 feet girth. *A. grandis*,

lanted by H.R.H. the Duchess of Cambridge, April 11, 1866; 6 feet girth. *A. Nordmanniana*, planted by the Right Honourable the Earl of Shrewsbury, April 20, 1866; 4 feet girth. *Cedrus atlantica*, planted by the Duchess of Sutherland, November 13,

to a height of 60 feet. *Abies Pinsapo*, planted by H.R.H. the Princess of Wales, April 4, 1874; 6 feet girth. *Cupressus Lawsoniana*, undated, 8 feet girth, 50 feet high. *Abies brachyphylla*, planted by H.I.H. the Czarewitch, June 29, 1894. Oak, planted

the Douglas Firs will become stately trees. Several old Oaks in the park range in girth from 17 to 30 feet; the latter measurement is quite correct, but an Oak with a diameter of 10 feet is certainly phenomenal. There is a Hornbeam with a girth of 10 feet, a Sycamore with a girth of 9 feet, and a Turkey Oak with a girth of 10 feet. The oriental Planes were in grand plumage, and are probably the best the Society has ever seen. A Medlar, in fruit, 33 feet high, was noted, as well as evergreen Oaks over 30 feet high, in splendid foliage, and well arranged. In the private grounds is a perfect specimen of *Picea pungens glauca*, 9 feet high. A broad-leaved English Elm, 42½ inches (quarter girth) 3 feet up, merited attention; and hanging over the lake, between Sandringham House and York House, we found a *Salix babylonica*, 40 feet high—a most elegant tree with a beautiful weeping habit. In walking from the kennels to the stables, there are two very conspicuous specimens of *Coniferae*—the one *Pinus Jeffreyi*, 50 feet high; the other *Abies nobilis glauca*, 95 feet high. Both are noble specimens of their kind. To the horticulturists, the bedding in front of Sandringham House was a source of real pleasure, and was much admired. The style was quite new, and most effective, the foliage plants and flowers being very artistically intermixed. The Japanese Honeysuckle in the vicinity of York House was also most beautiful. *Transactions of the English Arboricultural Society.*

BELGIUM.

PLANTS AT L'HORTICULTURE INTERNATIONALE.

THERE is now here a fine show of *Lælia præstans*, of which there are many interesting varieties; amongst them *alba*, which is as rare as beautiful. There is also a fine importation of *Cypripedium bellatulum* from Burma, splendid plants, and in full vigour. *Aërides crassifolium* is also a new and interesting importation.

Dendrobium nobile chinense blooms well, and is valuable as a cut flower. This Chinese species flowers from the pseudo-bulbs, and with rare abundance. I believe it may yet rival *Odontoglossum crispum*. Numerous and good varieties of *Dendrochilon glumaceum* are in bloom, and are most delicate and sweetly scented.

Odontoglossum Wilckeanum, which last year was much admired for its great beauty, is now beginning to flower again, and maintains the reputation previously gained. This will afford specialists an opportunity for studying the great variety observable in the flowers of *Odontoglossums*. *Ch. de B.*

AMERICAN NOTES.

THE DWARF SWEET PEAS.

THE enthusiastic Sweet Pea connoisseurs, Messrs. W. Atlee Burpee & Co., of Philadelphia, are introducing this year their new Dwarf Sweet Pea, Pink Cupid. This is a sport from Cupid, the original dwarf white variety, and is said to be somewhat stronger in constitution and easier to grow. The same company promises two more dwarf varieties for 1899, Primrose Cupid, and Eliza Eckford Cupid. This energetic development of such a striking line of novelties is all very delightful, and no one would have the heart to criticise it in a firm which has done so much for Sweet Pea culture in America; but after all, the Dwarf Sweet Peas have not proved to be of any great interest to the ordinary grower of garden flowers, and they do not seem likely to affect favourably or adversely the immense popularity which the Sweet Peas in general are now enjoying.

SOME NEW FLOWERING PLANTS.

A new strain of Hollyhocks, under the general name of Alleghany, introduced last year by Mr. A. E. Wohlert, gardener to the Pennsylvania Railroad, has met with general favour, and is advertised in nearly all the plant catalogues for 1898. The strain is

FIG. 34.—KÄMPFERIA ETHELE: FLOWERS ROSY-PURPLE. (SEE P. 94.)

1865; 5 feet girth. *Abies Pinsapo*, planted by Prince John of Glucksburg, May 5, 1871; 4 feet girth. *Cedrus Libani*, planted by H.R.H. the Prince of Wales, February 10, 1872; 8 feet girth. *Sequoia gigantea*, planted by H.R.H. the Crown Prince of Denmark, April 20, 1878; 4 feet girth. Other *Wellingtonias*, undated, range from 10 to 15 feet in girth, and rise

by H.R.H. Prince Edward of York, October 5, 1896. The acorn of this Oak was planted by Mr. John Jeffreys on July 6, 1893, as a memento of the marriage of the Duke and Duchess of York, and it appeared above-ground in the middle of June, 1894.

Good specimens of *Sequoia gigantea*, of *Cedrus Deodara*, and Douglas Fir are to be seen. In a few years

somewhat like the Japanese Hollyhocks introduced several years ago, having the blossoms, especially of the inner parts, beautifully frilled and fimbriated. The varieties show a wide range of colour, but colours and forms have not yet been selected to an extent to make them very stable. A fair proportion of the seedlings, though, always prove desirable, and the strain is likely to meet general approval.

The Orchid-flowering Cannas are advertised in all the catalogues for 1898, and will probably be seen quite commonly in gardens hereafter. Italia, Austria, and Burbank, seem to be the only varieties generally offered, which is really unfortunate, for such varieties as America and Pandora would surely add materially to the limited appreciation which the Orchid-flowering Cannas have awakened in America.

The Dahlias are enjoying a revival of interest in this country, and dealers are finding a demand for considerable quantities of roots of the finest varieties. The Cactus-Dahlias seem to be special favourites. F. A. Waugh.

THE SEASON OF 1897 AT ISLEWORTH, MIDDLESEX.

THE weather of the past year was not marked by any real extremes, although a retrospect shows it to have been a disappointing season in most respects. April and May were cold, droughty, and a very unfavourable seed time, so that the hot months of June and July, failing to give us any really heavy rains, found vegetation drought-stricken and unable to make much progress. Such conditions, of course, produced precocious flowering, and a general falling of all tree-fruits.

The autumn was cool, dry, and very favourable. The average maximum for the year was 57° (1° below average), the maximum temperature 94°, and the minimum temperature 22°. The rainfall 21.52 inches.

The night temperatures during the summer, until August came in, were very low, minima as low as 41° occurring in July. On the other hand, the day temperatures were above the average, and 70° was touched on seventy-nine days.

Frost was registered on fifty-three nights during the year, but there was no severe cold. Snow was visible on seventeen days.

FLOWER GARDEN.—The copious rains (6.83 inches) of February and March produced almost ideal conditions for the flowering season of our spring bulbs in the beds and borders, and I have never seen Hyacinths, Scillas, and Narcissi generally bloom to such perfection or in such profusion. My experience here being quite the reverse of many of your correspondents in this particular.

The later-flowering bulbous and tuberous rooted plants were failures, owing to the drought of April and May, and the dry conditions ruling throughout the summer. The Japanese Lilies and Dahlias were especially affected, and also the Begonias, although I think the cold nights were perhaps as much to blame for this latter failure.

Tulips made a brave show as usual, although frosts in the middle of May bleached the later early-section.

Among bedding plants Zinnias and Asters did well, and the perennial section remarkably so.

Although the midsummer heats were distressing to pot Chrysanthemums, the autumn (dispite the fogs) was favourable to them. A few choice varieties are made a specialty of here, particularly (1) W. Seward, (2) W. Holmes, (3) Elaine, (4) Ryecroft Glory, (5) W. Stevens, and (6) Cullingfordi. Many of the "exhibition" and "size-above-quality" section have had to be relegated to verandah work, on account of their coarse appearance.

I found Ryecroft Glory and W. Stevens stand very well out of doors, where others failed or were spoiled by the weather.

Lycoris squamigera has become thoroughly established outside, and this year produced 150 flower-scapes (3 to 7 flowers to the scape) which were all in bloom at one time in early August. L. sanguinea (var.) also produced three scapes outside, but I have doubts for its future well-being.

Brunsvigia, of sorts, only produced a dozen blooms out of doors, or about a third of their average amount of bloom. Several tubers of Arisaema fimbriatum planted out in a shady place in June mostly produced spathes in August, and strong leaf growth; so probably this can be used in the same way as many of the Amorphophalli, although it has hitherto been considered as a stove species.

Hippeastrum alicum flowered well outside in August, so that both this species and H. sub-barbatum (Herbert) can be utilized in this way. The difficulty lies in the after-treatment, so as to prepare the bulbs for flowering again another year. This is, however, of a special nature, into which it is impossible to enter shortly.

Garden tuberous Begonias have remained in the soil at the foot of a wall undisturbed for two winters, and flowered again this season, but very late. So also has Oxalis cernua, but I should doubt either surviving a severe winter unless covered up. Oncidium incurvum again flowered well outside for a prolonged period and was much admired.

FRUIT.—Pears and Apples carried very variable crops, one tree having no fruit at all, and the next to it being over-loaded; but generally the result was under average. The

ripening period being cool and dry, the fruit was generally well finished, and of good keeping quality. Cox's Orange was a failure, Blenheim a heavy crop of fine fruit. Among the Pears, the old Bourré Bosc (locally called Calabasse or Calabash) again proved itself to be a heavy and regular cropper, and of superb flavour, second only in my estimation to Marie Louise, which this season failed to produce any fruit whatever. The once much-extolled Pitmaston Duchesse has, after several years' trial, been extirpated as utterly worthless for any purpose except that of exhibition.

Damsons were an absolute failure, and Plums generally a very poor crop. Apricots were scarce; Peaches a moderate crop of fair-sized fruit; Mulberries scarce, also Walnuts, but Filberts and Cobnuts a bountiful crop. Morellos average; Quinces good. Among small fruits, the Gooseberry crop was simply wonderful, the best I have ever seen. Strawberries fair, the variety "The Countess" being the best flavoured of the year. Raspberries very poor. Brambles (of sorts) prolific. Currants under average.

VEGETABLES.—There was no disease among the Potatoes (Sutton's Snowball the best quality); Peas and Lettuces suffered from drought.

Conservatory, &c.—The noticeable results of the year have been (1) the flowering of Eucharis Lehmanni, and Hymenocallis Moritzianum, and the raising of seedlings in both cases; (2) the securing of the mature fruit of Elisena longipetala. This has an important bearing botanically, as it throws doubt upon whether the genus should be any longer separated from Hymenocallis. A. Worsley, Mandeville House, Isleworth.

TITMICE.

ALL the titmice are more or less active hunters of insects, for which they are constantly on the watch, and no inhabitants of the insect world come amiss to them as food. They are especially useful in the destruction of many crop-pests, which they devour in all stages. During the winter they clear off enormous quantities of eggs which have been deposited by insects of various kinds in dormant buds, or near the buds, and in the clefts of the bark or rind of trees. At this season the titmice may be seen frequently running up and down the trunks, stems, and branches, or hanging head downwards from the smaller branches and twigs, prying anxiously into each crevice and fold of the rind in search of eggs, hibernating larvæ, or perfect insects. Their sight is so keen that they can detect such small eggs as those of the Winter-moth, and they have been seen actively devouring the minute red eggs of the Bryobia upon the stems and branches of Gooseberry-bushes and Damson-trees.

It is sometimes alleged that the tits, like the sparrows, pick out the buds of trees and shrubs, either wantonly or for food; but this accusation is wrong, and based upon insufficient investigation of the circumstances, as titmice attack only buds that are infested—for example, Apple, Pear, Plum, and Damson buds infested with the larvæ of the Winter-moth, or the larvæ of the Apple-blossom weevil.

The crested tit, Parus cristatus, is a pretty little bird, but it is scarce, and decreasing in numbers. It feeds upon insects and weed seeds, and should for this reason be carefully preserved. Yarrell, Seebohm, and Harting remark upon the rarity of this bird.

The coal-tit, Parus ater, though somewhat common, is not so well known as the great tit and the blue tit, since it is not domesticated, and lives in woods, copses, and shrubberies distant from houses. It is frequently found in Birch and Pine-woods. "Birch-woods," says Seebohm, "are the favourite haunts of this bird during the breeding season, where the abundance of holes suitable for nesting purposes is probably the chief attraction."

The coal-tit is as great a destroyer of insects as the other members of the same family, and should be rigorously preserved. Yarrell, in writing of this bird, says that like the blue tit it is constantly in motion, roving from tree to tree in active search for those small insects and the seeds of various evergreens, upon which it principally exists.

The coal-tit is rather more than 4 inches long. Its general colour is bluish-grey, with a dull white breast, and it may be distinguished from the marsh-tit, which it somewhat resembles in colour and size, by a large white patch on the back of the neck, and by white spots on the wings. It usually makes its nest in holes in trees and stumps of trees; but Lord Lillford says that he has always found the nests in

burrows and holes in the earth made by rabbits and other animals.

The marsh-tit (Parus palustris) is not so common as the species just described, and is of rather small size. It is occasionally seen in gardens and orchards principally in the winter; but its chief habitats are low-lying meadows and damp situations, where nests in holes in old Willow-trees and other tree pollards, and stumps, very close to the ground. It is insectivorous. Yarrell states that it is also partial to the seeds of the Thistle.

According to Seebohm, it may be seen in almost every conceivable position, searching for insects on buds at the end of a branch. It is slightly smaller than the coal-tit; its head is bluish-black, the sides of the neck are white, the under part of the body light brown, while the upper part is olive-brown, varying shades. It builds its nest much in the same manner as the coal-tit, in holes in stumps of trees and in holes in the earth. Board of Agriculture, Whitehall Place, S.W.

To be continued.

A NEW COTTON-PLANT.

"THE variety of cotton in question has only been known to civilisation for a couple of years. It was first discovered in the region of the Congo by an explorer named Adolph Kyle, an English Jew, who, with a few other young men, started on a prospecting tour in Central Africa in December, 1892. One day towards the end of the following year, they pitched their camp on the outskirts of a village 20 miles south of the Equator, and about 1000 miles from the coast. He observed growing near the camp thicket of mammoth Cotton-plants, 20 feet and over in height, and covered with bolls. The plant was limbless, and bore its seed-pods at the base of its broad Fig-like leaves, and only a few inches from the stem. The native villagers were utterly ignorant of the utility of the product of the shrubs.

"This year (1897) he (Mr. Jackson, a farmer to whom some seed was given) has planted 6 acres, and it is said that he has 'the most magnificent field of Cotton ever seen in Georgia.' Although the season has been unfavourable owing to a prolonged drought, the yield of this crop is estimated at four and a half American bales (containing 600 lb. each) per acre. Experts who have seen the crop are of opinion that the crop is superior even to the far-famed Sea Island product.

"The plant is quite different from that of any other variety of Cotton grown in America. The stalk is stout and straight, and supported by a rough fibrous bark. The blooms open at night, and are cylindrical instead of flaring, so that they do not admit the rain, which causes the dropping of the fruitage in wet seasons; the leaves drop out of the way as the bolls ripen, and the locks hang loosely in the wide open bolls, so that the crop is easily harvested. The new Cotton has attracted a great deal of attention in the United States, and Farmer Jackson has a rush of Cotton-growers, buyers, and mill agents from all over the country to see his wonderful crops, the product of which has been purchased by one of the largest southern mills. It is estimated that the general use of this Cotton in the Southern States will reduce the area necessary to be sown for the present average yield by fully 60 per cent." *Indian Textile Journal*, Nov. 15, 1897. (We should like to see a specimen of this novelty. ED.)

FLORISTS' FLOWERS.

NOVELTIES IN CHRYSANTHEMUMS.

THE novelties of the present season are again numerous, and I have seen amongst them some varieties that are really promising. There are several crimson-flowered varieties that will be especially welcome, as the colour is not by any means common in the large-flowering type. In fact, two of these are likely to rank among the very best. Joseph Chamberlain has long, drooping florets of exceeding rich colour, and is said to be a seedling

from Edwin Molyneux—a fact greatly in its favour. S. W. Gilbert, judged from a bloom I have seen, is much like a crimson Etoile de Lyon. Then there is the sport from Madame Carnot, known as Mrs. W. Mease, which has a pale creamy-yellow flower, and which has been exceedingly well shown by the raiser.

rosy-peach. Frances B. Hayes has a flower of very fine build, the florets loosely drooping, incurving, and in colour a pretty shade of pink. Matthew Hodgson, though not so novel, should be grown by all who like a bright and effective colour. I have not seen it often exhibited, but the plant is a vigorous grower,

FORESTRY.

DEGREES OF THINNING.

WITH regard to Oak, although freely used on most English estates for gates, fencing, &c., on account of its being conveniently at hand, it cannot be looked upon as a tree which is planted chiefly for estate purposes; in fact, except as a unit to the ordinary mixed plantation, the planting of this tree is almost entirely neglected at the present time, chiefly on account of its relatively slow growth. But where a sound and permanent system of forestry is to be inaugurated or maintained, we contend that Oak should still form the backbone of woods on heavy soils, for good English Oak never lacks, nor probably will lack, a purchaser, which is more than can be said for the timber of many species. But Oak timber of the present and future is, and will be, put to very different uses to what was the case a century ago. The "wooden walls of Old England" now exist only in verse and tradition; and in view of the development of modern naval architecture, it seems hardly possible to believe that the British Government should once have thought it worth while to set aside a few thousand acres of land for the purpose of growing Oak-timber for the Navy. But while all ideas of this kind are now obsolete, it can hardly be said that the method of growing Oak for which they are responsible, are equally of the past. Less than a century ago, the most valuable part of an Oak-tree was its bark, and its crooked limbs, the latter forming knees for use in shipbuilding. The greater the number and size of the branches, the better the chance of getting these highly-prized crooks, and the greater the quantity of bark. Naturally, therefore, the old system of thinning Oak brought the density of the plantation very much on a par with that of a Kentish Cherry-orchard, and a plantation specimen differed little from one in a park or hedgerow. Probably to prevent what was considered as a waste of ground, the plantation was filled up with Hazel-underwood, forming what is generally known as coppice, with standards, the latter having every inducement to form large, spreading heads, and short, thick boles. It need hardly be said that the demand for trees of this type no longer exists, although the method of producing them does. With bark at a price which just pays for taking it off and no more, and the once-valued crooks worth their weight as firewood, the man, or rather the series of men, who aim at producing marketable timber, must adopt other methods. Straight, clean timber, of large size, and free from cup- and star shape, now fetch the top price, railway companies using such stuff for wagon-building, &c. Oak timber of this class wants a good soil, a warm climate, and a healthy and vigorous crown of foliage to produce it, and given these and fair treatment, we believe Oak plantations would prove as profitable in the long run as the majority. With the long-lived tree of this description, the survival of the fittest principle comes greatly into play, and the production of first-class timber depends less upon the degree of thinning than upon the constant weeding out of individuals which show little promise of becoming sustained growers. Nothing defeats this end more than the rule-of-thumb species of thinning, which keeps the so-many-feet-apart idea steady in view.

How often do we find a group of three or four Oaks or other trees in woodlands left pretty much to themselves, which all stand on a piece of ground 6 yards square, and yet contain more good timber than a dozen carefully thinned out trees elsewhere. The explanation of this probably lies in the fact that the soil at that particular spot is deeper and richer than the average, and is able to sustain a much greater growth of vegetation, and the moral is "take full advantage of it." The policy of the thinner of an Oak plantation should be that of carefully picking out these exceptionally favourable sites, and giving the trees thereon every opportunity of reaching maturity. While keeping them sufficiently thick to encourage altitude in the early stages, they should

FIG. 35.—STERNBERGIA MACRANTHA: FLOWERS YELLOW. NAT. SIZE. (SEE P. 94.)

A bronzy-coloured sport from Edith Tabor, named Mrs. Banks, will be likely to prove a very good variety; Mrs. J. Gleeson, a pretty rosy-apricot shade on a yellow ground, florets loosely incurving; W. Towers, a very promising yellow Japanese, and Mary Molyneux, are all likely to be good; the colour of the last-named is rosy-lilac, shading to a beautiful

and of dwarf habit. Plants of G. J. Warren distributed last spring were probably too weak, or it will not prove so satisfactory as its parent. I have not heard of a really good first-rate flower being shown this season, and, in my humble opinion, a guinea is too much to pay for a plant that is not vigorous enough to produce an exhibition bloom. E. Knowles.

never be left unthinned long enough to get drawn up and lose a properly balanced crown of foliage, for such conditions favour shaky timber as much as anything next to quality of soil. Other parts of the wood which exhibit a slow or unhealthy growth had better frequently be thinned and cleared comparatively early, and the ground replanted with something more suitable. If mixed freely with Ash at the time of planting, the thinner has the option of taking out or leaving whichever species he finds doing best, while young Ash timber and poles are more valuable than Oak as thinnings.

It is a great mistake, however, to attempt to raise really good Oak woods on the mixed plantation system, and planting single Oaks 30 or more feet apart, in the expectation that each one is going to make a satisfactory tree. In such cases the principle of natural selection never comes into play, and more often than not the plantation never becomes an Oak wood at all, but a mixture of inferior Larch and other Conifers, which produce almost worthless timber on typical Oak soils. Now-a-days, the latter are not planted to any great extent as a means of utilising the soil economically, except perhaps on high and exposed situations, and in such cases the desirability of introducing something which will grow quicker than Oak under the given conditions, is conceivable, and may necessitate a different system in which the Oak is less predominant. *A. C. Forbes.*

(To be continued.)

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Plum Trees on Walls.—Let the pruning and nailing of these trees be finished without delay. If the fruit-spurs are, as is often the case, of great length, the flowers are more exposed to injury than when the spurs are short, and as the Plum breaks from the old wood very freely in all but very aged trees, these should be shortened or removed. Every young fruit-spur should be shortened to back buds annually, and well-placed young shoots laid in by the side of the older main branches, removing the latter as those become fit to fill their places. It is a mistake to be avoided to train in young shoots thickly, as the fruits require light and air when ripening, in order to obtain their proper colour and fine flavour, and the young shoots and branches should have not less space than 4 inches between them, and in the case of large-foliaged varieties like Cox's Emperor and Magnum Bonum, 5 inches should be the minimum. Plums like Imperatrice having small foliage may have less than 4 inches; still it is a good rule to adhere to, as from their lateness in ripening the fruits require every ray of sunshine.

Plum-bushes.—When Plum bushes are much restricted in size, they seldom fruit satisfactorily, owing to the strong annual growth that is made, the only remedy for which is periodical root-pruning. Bushes are, however, more suitable for small gardens than are large standard trees; and it is an easy matter to protect the bloom from frost and the fruit from the birds. The roots of the Plum are very prone to throw up brood—in garden parlance, "suckers"—more especially when the ground is under the spade, and to extirpate these the offending roots should be bared with a spade at this season, and the shoots severed without injuring the roots. These suckers if furnished with roots will, if planted in nursery lines in the reserve garden, form stocks for budding and grafting in a year or two. The Cluster or Crittenden Damson is a variety usually standing on its own roots, and its suckers are, therefore, true. Although not a Damson of the best quality, the Cluster is useful in a scarce year, as it is seldom fruitless, even when all other varieties fail. Last year the fruit was worth £20 per ton. Another small Plum, Mirabelle, is most valuable for all sorts of cooking and preserving purposes; but it is almost unknown in this country, although much grown in Germany, the growth is very similar to Cluster Damson, the fruit pale yellow, sweet, smaller than the common Damson, almost round, and of nice flavour when cooked or preserved. Some authorities confuse this variety with White Myrobalan, from which it is quite distinct, and far more certain in cropping.

Black Aphis on Cherries.—This, one of the worst pests the fruit-grower has to contend with, usually appears plentifully when the fruits are swelling, and therefore when the use of insecticide is pro-

hibited. Badly-nourished trees are more liable to attack than those possessing vigour, and much arises from root-feeding. To do this the more readily, bare the upper roots, and apply 4 inches of decayed cow-stall-manure, and mix some good turfy loam, equal to one-half of the staple, mixed, and a few barrow-loads of plaster or finely-broken chalk per tree, returning the whole after well mixing it together over the roots, and make it quite firm by treading it. Before the buds expand, syringe the trees with a solution of soft-soap, 24 oz.; common brown carbolic acid, one wineglassful; rain-water, 4 gals., well stirred together, and choosing a calm day; apply it over every part, and do not wash it off the trees. While it is being used, the mixture must be kept stirred or the acid will come to the top. It is important that this should be done while the buds are still firm and before growth advances, a little green showing does not signify, but if the buds are much swollen the acid will burn them. On referring to my note-book I find March 19 was the day we did our trees last year, but this season the date will be much earlier. If Lettuce or Parsley are growing at the foot of the Cherry-walls, the solution if it touch them will destroy them.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Zonal Pelargoniums.—Plants which, since flowering, have been kept dry, may be pruned close back, and afterwards placed in a gentle heat, to enable them to break into growth. For increase of stock, cuttings may be inserted in sandy soil, and placed in a warm-house near the glass; and young plants may have a shift into 5-inch pots, making the soil firm round the ball, in order to insure short, sturdy growth.

Cliveias.—Last year's seedlings, which have hitherto been in a cool-house, may be shifted into larger pots, using a potting-soil of rich, friable loam, leaf-mould, rotten manure, and sand; pot firmly, afford water, and place the plants in a house having 55° of warmth. They will soon start into growth, and make strong plants during the summer. Old plants which have been partially rested may be started in a gentle heat to flower them, and when in active growth be afforded abundance of water, and occasionally manure-water.

Dipladenias.—The plants having been kept somewhat dry at the roots may now have the weakly growths removed, and be sponged over to clean them of insects; and those which need more root-space may be repotted in a compost consisting of peat, loam, sand, and small pieces of charcoal, and in well drained pots. Water will not be required before growth pushes freely; and plants that do not require shifting may be top-dressed. Let the growths be trained close to the glass in a light part of the stove, as the plants revel in light, heat, and moisture when growing.

Lapagerias.—Let all weak shoots be removed with the knife, and the main growths untwined and regulated, for nothing is gained by tying in many growths in a bundle; on the contrary they become weak, flowering not at all, or unsatisfactorily. Afford every part of the plants a copious syringing with an insecticide, both when the growths are unloosened, and after tying them in. A close watch must be kept for slugs of all kinds, which are partial to the tender young shoots, protection being afforded by forming a ring of tobacco-powder around the base of the plant, and sprinkling some over the young shoots as growth proceeds, or by placing a piece of wadding the woolly side outwards round the stems close to the ground. If planted out, remove all the soil down to the roots, replacing it with a compost consisting of good lumpy pieces of loam and peat, plenty of sand, and some small pieces of sandstone. Be sure that the drainage is clear, and in good order. Any of the plants that are growing in pots or tubs that require more rooting space may be repotted, and placed on a cool base in a cool-house, watering them carefully till root-growth is active.

Achimenes.—The tubers, or some of them, may be shaken out of the worn-out soil in which they grew last year, and be placed thinly and regularly in baskets filled with light soil, such as peat one half, leaf-soil one half, and plenty of sand, or they may be placed rather more thickly together in shallow pans, just covering them and no more with soil and starting them in gentle heat, affording no water at the first, or until the tubers begin to grow, and shading them from strong sunshine. When 2 to 3 inches high, lift each tuber or several together, and plant these in pots or baskets at about 2 inches apart.

Primulas.—Plants now in small pots and intended for flowering next autumn, must not become root-

bound before they get a slight shift, or be allowed to produce any flowers. Seeds sown at this date furnish plants that will flower late in the autumn. The seed-pans should be filled the day before sowing with a mixture of equal parts of loam and leaf-mould with plenty of sand added, and be afforded water to moisten the soil. When the seed is sown, just sprinkle a pinch of silver sand over it, and cover with a sheet of glass; shade with a bit of brown paper and place in a mild hot-bed, no water being applied for some time. Plants in bloom will require manure-water occasionally, and a temperature of 50° to 55°, with plenty of air whenever possible.

Cyclamens.—If seed has not been sown for another season's supply of plants, no time should be lost in sowing some in pans filled with moderately light soil, the seeds being barely covered with the mould. Place in a brisk heat, and when the plants appear, place close to the glass, and admit air gradually.

Fuchsias.—Any of the plants after a period of rest may be brought into gentle heat. If pyramidal-shaped plants are desired, cut back the side-growths close to the previous year's growth, and shorten the main leader. Plants struck in the autumn of 1897, as soon as growth becomes active, should be sifted into larger pots; and if more plants are required, some of the old plants should be left unpruned, and placed in a brisk heat in order to afford cuttings, and after taking off the required number of cuttings, these plants may be cut hard back.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

Winter Broccoli.—Examine the plants frequently, cutting every head which is large enough for consumption, and if a larger number of heads are turning in than can be kept in good condition if removed from the plants, lift the plants on a dry day, and heel them in, in a cold pit or shed. I have this season had very superior Broccoli from unprotected plants—an unusual occurrence in this part of the country.

Autumn-sown Lettuce and Onions.—The plants in handlights should be freed from decayed leaves, and the surface of the soil loosened. The Lettuces planted on south borders should have vacancies in the rows made good from the seed-beds, and dead and decayed leaves removed, some dry soot being spread between the plants to deter slugs, and mix the soot with the soil by using the Dutch-hoe. The Onion-beds should be hand-weeded, and the plants made firm in the soil by trampling carefully on each side of the rows, as they are sure to have been loosened by frost; after doing this, lightly hoe the ground.

Dwarf Early Peas.—Make a sowing of some early Dwarf Peas on a warm border or other sheltered part of the garden. Good varieties for this sowing are May Queen, 2 feet in height; Chelsea Gem, height 15 inches; Early Sunrise, 2½ feet in height; and William Hurst, 1 foot in height, a space of 2 feet between the rows being afforded. Those who prefer taller-growing varieties should sow Ringleader, height 4 feet; Improved William I., height 3 feet; Kentish Invicta, height 3 feet; and Sangster's No. 1 (syn. Daniel O'Rourke), height 4 feet.

Broad Beans.—A good sowing of Broad Windsor, Green Windsor, and the Green Longpod Beans should now be made in the open, in soil which has been heavily manured, in rows 2½ inches deep, and 3 feet apart. The Windsor varieties do not commence to form pods before the eighth leaf from the bottom of the stem. Those who like white-seeded Beans may sow Sutton's Mammoth Longpod, which is both early and large. The earliest podding Beans are Dwarf Fan or Cluster, and Beck's Dwarf Green Gem, for although dwarf, they are great bearers, and they force well in frames.

Globe Artichokes.—If it be considered necessary, owing to the age of a plantation, to make a new one, seeds of the Green and Purple Globe varieties may be sown in a seed-box or pan, placing the same in a structure possessing a temperature of 50°, and when the seedlings are large enough to be handled readily, pricking them off into a frame placed on a shallow hot-bed, and growing them therein till the end of April, when, after due hardening-off for several weeks, they should be planted out in autumn-trenched and heavily manured soil in part of the garden free from trees, 4½ feet apart each way, and fully exposed to the sun. Heads can be cut in the autumn following from seedling plants. Old Artichokes produce under ground around the root-stock or neck, a number of shoots, "suckers," and these are usually more numerous on each plant to allow of full develop-

ment. The plants in March, when the protective covering is removed, should have these suckers exposed, and all but about three of the strongest removed, this being done without unnecessarily wounding the old stools. The best of these suckers should have the wounded parts of the heel trimmed off, and the leaves shortened a little. These may then be planted in the manner recommended for seedlings, or they may be planted in nursery lines, and planted permanently in June or July, thus rendering the results more certain. By planting suckers from proved good varieties, and at various periods from March to July, Artichokes of good quality can be sent into the kitchen for six months in succession without a break.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Early Peaches.—After the fruit is set, and before the young shoots become crowded, some amount of disbudding should be done by removing the back and front buds, and on parts of a tree where many of these buds appear remove a shoot here and there, taking care, however, not to remove the best placed lowermost shoots, which will be required in building up the tree, and in their turn to bear fruit next year. The disbudding should be done at intervals of five or six days, so as not to distress the trees, as the removal of many buds at one time would do. In disbudding never omit to leave a shoot in front of a fruit or fruits in order to induce a flow of sap, the resulting shoot being either stopped by nipping the point later or allowed to reach its full length as the case may require. Old weak wood on which the fruit is not set may be shortened back to a young shoot, and in some cases to the young shoot nearest its base. As the shoots grow in length, draw them carefully to the front side of the wires or wooden-trellis, and as soon as they are long enough, fasten them with bast, passing it round the old wood and the young shoots so that the shoot starts in a straight direction from the old wood. If after the fruit is set aphid infest the shoots and leaves, vaporise the house with XL All-compound, which, at this season, is the safest and most effective thing to use if the instructions are adhered to. The thinning of the fruits should be done at various stages of development, first when the largest are of the size of a Hazel-nut, and taking off all fruits situated between the branches, and the smallest where they are too close together to allow of full size being attained. A little thinning of the fruits should be performed each week till stoning takes place, leaving a few to be taken away after that period is finished. Do not remove the fruits indiscriminately, but leave those which are seen to be increasing in size faster than others, and leave much of it on the sunny-side of the tree. The temperature of the early Peach-house should range from 55° at night to 60° to 65° by day with artificial heat, and from that to 75° with sun-heat, and allow it to rise 10° higher on being closed early in the afternoon. At dusk the upper ventilators may be opened a small space, and remain open during the night if the weather be not unfavourable; and maintain a somewhat arid atmosphere, so as to keep the wood and foliage firm and healthy. A syringing of the trees daily, more or less, according to the state of the weather, is good for them, but for the present once on fine days will suffice, and later, twice on fine days. When syringing a tree, direct the water on to both sides of the leaves, and do not always syringe the trees from one side only. Should mildew show itself on fruit or foliage, mix half-a-pint of flowers-of-sulphur into a thick paste with a small quantity of water, then blend it with 2 gallons of water, apply with a syringe, wetting the fruit and the foliage, and for a few days discontinue syringing with clean water. The borders will probably require attention in the matter of water, but first have them examined, affording copious waterings if the soil is found to be deficient in moisture, and as the season advances frequent applications will be required. The water afforded should always be tepid. Farm-yard-drainings may be added to the water alternately, and do not allow the soil to become very dry at any season.

Strawberries.—In order to assist fertilisation, the flowers should have a feather or hare's tail passed over them about noon, that is when the pollen is fairly dry and easily distributed. The reducing of the number of flowers, or of fruit, should be performed so that the strength of the plants be not wasted. For many years I have practised the thinning of the flowers when rather more than were sufficient for a crop were expanded with satisfactory results. The number of fruits that a plant will bring

to perfection depends upon the variety, whether it is large-fruited or otherwise. Large-fruited varieties, growing in 5-inch pots will carry six fruits, and if in 6-inch pots ten. When thinning is not practised, the production of first-class fruit is not so great as when thinning is practised. The plants should be strong ones to carry the numbers given above, and if weak the crop should be one or two fewer fruits per plant. Plants with flowers set should have a liberal supply of water at the root as often as moisture is required, which will vary in accordance with the weather, water being always afforded before the soil has got dry. If manure-water be afforded, it should be much diluted, and used at every third watering. If an artificial kind be used, it should be readily soluble when sprinkled on the surface of the soil near to the edge of the pots. No reliance should be put on any one kind, but changes made from time to time. Red spider will be sure to give some trouble, and the best check to the ravages of this mite is to thoroughly syringe the plants on fine days in time to let the plants get dry before nightfall. If the plants stand on shelves near the glass, it is not difficult to wet the under sides of the leaves, where red spider chiefly harbours. Fumigate the plants, if aphid be present, in order to have them clean when the fruit colours. Never fumigate the house when fruit is colouring, as it imparts a disagreeable flavour to it. Let the ventilation be more or less according to the state of the weather, and close the house soon in the afternoon, but afford a slight amount again at dusk if there be no frost or strong wind. Let the temperatures range from 60° at night, 65° on dull, and 75° on sunny days. Do not practice syringing the plants when the fruit begins to colour, or apply manure of any kind; and afford less water and fuller ventilation.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Violas.—The autumn-struck cuttings, or those plants which have been raised from seed sown in the months of August and September, will now be ready for planting in the beds or borders, thus having time to get well established before dry weather occurs. Violas are now become almost indispensable plants in affording material for midsummer bedding, especially as ground work or carpeting under taller plants, and the colours of many of the varieties lend themselves admirably to the prevailing methods of planting, besides affording a long season of flowering.

Violets.—The removal of decayed leaves from these plants will require constant attention. The plants are blooming a great deal earlier than usual; and the fogs and humid atmosphere have caused considerable loss by the damping off of the leaves, especially with the more compact growing double-flowered varieties. Where hand-lights or frames are placed over these, on outside borders, great care should be exercised previous to the placing of them to see that all decayed matter be removed, and that a light surfacing of leaf-mould and sand be placed around them, which will aid in preventing damping off, and afford nutriment to the lateral roots of the plants; afford air liberally in mild weather.

Annuals.—It is quite time that a careful perusal was made of the seedsmen's catalogues, with a view to acquiring those varieties of flower seeds which will make the garden as bright as possible during the summer and autumn months. For outdoor sowing, the following are amongst the best:—Candytuft, in three distinct colours, white, crimson, and carmine; the average height of each is 1 foot, and the spiral varieties are most effective and useful as cut flowers. *Linum grandiflorum*, in three colours, white, blue, and scarlet, the last colour being the most effective; for continuity in flowering, and when an elaborate display of colour is required at a minimum cost, the *Linum* has no equal. For small beds, or for edgings of larger ones, the dwarf varieties of *Nasturtium* are exceedingly pretty. These can be obtained in various colours; they average in height from 6 inches to 1 foot, and bloom profusely if planted in poor soil. Of *Nemophilas*, insignis, the bright blue flowered one is the best, and varies in height from 6 to 9 inches. It makes a bright display of a colour peculiarly its own, but to maintain continued bloom two or three sowings are needed. *Saponaria calabrica* is another capital annual, the flowers in their shape suggest a cross, and are borne in great profusion, and continue for a considerable time. It rarely grows more than 6 inches in height, unless in very strong soils, and is therefore exceedingly useful as an edging plant. The varieties enumerated above, with the addition of the several varieties of Marigolds,

will, if properly treated and the seedlings well thinned out, afford at a little cost great satisfaction to those who grow them.

Dahlia Tubers and Cuttings.—When a large number of any special variety is required, and the stock of tubers is limited, the latter should be placed forthwith in an early vinery or other warm-house, with a not lower degree of warmth than 55°. With this temperature the cuttings are short-jointed, whereas in a higher degree of heat the cuttings come weak and long. The cuttings should be taken from the root-stock, stripped with, if possible, a bit of it, as this ensures quicker rooting. Dahlia cuttings root readily in sand or cocoa-nut fibre, if either be kept moist in a temperature of from 60° to 70°. Let them be potted-off as soon as rooted in any kind of light soil, with a fair amount of sharp-sand and leaf-mould mixed with it; and gradually harden off as the season advances. A sharp look-out must be kept for wood-lice, which are very destructive to the cuttings and young plants.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Epiphronites Veitchii ×.—Plants of this lovely hybrid are now showing their flower-spikes from the apex of the newly-made growths, and at this time if the compost be made too wet, the small leaves become spotted. This free-growing species should be kept in a cool, shady part of the intermediate-house. Do not remove the old stems when the flowers fade, because these frequently produce young plants, which should be constantly watched, so that as soon as they begin to root they may be removed with a portion of the stem attached, and put into small pots in sphagnum-moss only; in two or three months afterwards it will be necessary to repot them. The older plants should be repotted as soon as growth recommences into a rooting material of sphagnum-moss and a few pieces of fibry peat and broken crocks, taking care to well drain the pots. I have tried to grow this plant suspended near to the roof-glass, but it failed to thrive, though upon the stage, in company with *Miltonia vexillaria*, it grows luxuriantly.

Epidendrum Wallisii requires a similar position, and should now be watered freely. *E. Endresio-Wallisii* × and *E. elegantulum* ×, producing their spikes, need careful watering; both hybrids need the same treatment as the *Epiphronites*, and should be shaded from strong sunshine.

Miltonias.—Examine Brazilian *Miltonias*, and afford more rooting-space to any needing same. The dwarf-growing *M. spectabilis*, *M. Moreliana*, *M. Lubbersiana*, and *M. bicolor*, being scendant growers, require considerable space wherein to extend themselves, and shallow pans are suitable. Such of these plants that have become bare in the centre may be broken up, and all decayed bulbs removed from them before the growing pieces are made up afresh. The pans used should be quite half filled with drainage; and as compost, use good fibrous peat (devoid of fine matter) and a liberal quantity of broken crocks. In repotting the specimens, some of the pieces with but few roots must be pegged firmly down to the compost. *M. Clowesii*, *M. Regnelli*, *M. Russelliana*, *M. candida*, and its variety *grandiflora*, are strong-growing species, best grown in pots, using similar compost; and when potting, keep the plants well elevated above the rim of the pot, with the base of the bulbs just on the surface of the compost. Insert a few thick pieces of crock here and there among the peat, so that when the plants are in full growth, water may be given freely without causing sourness. Plants of *M. cuneata* must not be disturbed at present, as their flower-spikes are in course of development. All of these *Miltonias* may be grown in the coolest part of the intermediate-house, choosing a rather shady place for them. The rare *M. Schroderiana*, a distinct and handsome species, is now in full growth, and should be kept moist at the roots.

Masdevallia tovarensis having flowered, it is advisable to remove the spikes at once, because if they be allowed to produce secondary flowers, they tend to unduly weaken the plant. The plants are now making fresh leaves, and if any plant requires to be repotted, the work may now be done. Either pots or pans may be used, and it is very important that they be well drained; they should be filled up to within an inch of the rim with clean crocks, over which place a thin layer of moss, and keep the plant well up on a compost of fibrous peat and sphagnum-moss. Do not pack the material around the plant too closely, but compress it just sufficiently to make the plant firm. Water sparingly until the young leaves are well advanced. The coolest part of the intermediate-house will suit the plant for the present.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

MEETINGS.

MONDAY,	FEB. 14	{ National Chrysanthemum Society (Smoking concert).
THURSDAY,	FEB. 17	{ Linnean Society's Meeting.
FRIDAY,	FEB. 18	{ Annual Meeting of Royal Gardeners' Orphan Fund, at Anderson's Hotel, Fleet Street, E.C.

SALES.

MONDAY	FEB. 14	{ Border Plants, Shrubs, Roses, Fruit Trees, &c., at Stevens' Rooms.
TUESDAY	FEB. 15	{ Continental Plants, Roses, Greenhouse Plants, Begonias, &c., at Protheroe & Morris' Rooms.
WEDNESDAY,	FEB. 16	{ Japanese Lilies, Palm Seeds, Roses, Ornamental Plants, &c., at Protheroe & Morris' Rooms. Roses, Fruit Trees, Shrubs, &c., at Stevens' Rooms.
THURSDAY,	FEB. 17	{ Azaleas, Carnations, Hardy Border Plants and Bulbs, &c., at Protheroe & Morris' Rooms. 22 Cases of Araucarias, 200 Cases of Japanese Lilies, Plants, Roses, &c., at Stevens' Rooms.
FRIDAY,	FEB. 18	{ Important sale of Odontoglossum crispum and other Orchids, by order of Mr. Thos. Rochford, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—39° 1'.

ACTUAL TEMPERATURES:—

LONDON.—February 9 (6 P.M.): Max., 48°; Min., 36°.

PROVINCES.—February 9 (6 P.M.): Max., 50°, south-west Ireland; Min., 42°, east of England.

Weather—slight frost; showers; dull.

COMPLACENCY reigned at the general meeting of the Royal Horticultural Society, on Tuesday last, on all points but one, which will be referred to in another place. The President, council and officers are well entitled to indulge in this feeling, for they have done their best and have achieved success. Who that remembers the South Kensington times could have supposed such a measure of success possible? Whilst thanking all those who have contributed to this result, we may be allowed to congratulate the President on the widely altered circumstances and on his devotion to the Society through ill report and good report. He should have been the chief among the Victoria Medallists, and it is a pity that some such proposal was not put to the meeting.

We have already published the report and extracts from the balance sheet. Sir TREVOR LAWRENCE'S address to the Society naturally followed the lines of the report very closely, so that there is little room for comment. We may, in passing, allude to some of the points of interest. The expenditure on Chiswick amounting to £1800, or nearly one-third of the Society's income, shows no material diminution; but then, it must be remembered, that the establishment had during the evil days we mentioned been allowed to get into the uttermost state of disrepair. All that is put straight; old houses long condemned have at length disappeared, and new ones have been erected in their stead. The great vinery is in good repair, and the establishment generally is in excellent condition. The thought of deriving profit from Chiswick is out of the question; and it is a matter for regret that the

Society is forced under existing circumstances to devote any portion of its staff or their energies to the sale of produce. Commercial market-gardening can be better done by others, while by practising it the Society wastes energy which might more advantageously be devoted to other purposes. Chiswick should be within its limitations a model garden, an experimental garden, and an educational establishment. We hear of prizes and scholarships being awarded, but for what purpose is scarcely apparent. No course of instruction is given; and as for initiation into the principles of the science and art, there is none. Now that a Professor of Botany is appointed, something might be done to secure to the Chiswick lads a fuller modicum of instruction than they now get. We suspect that the feeling expressed by one of the speakers at the meeting to the effect that Chiswick is a "white elephant" is shared by many besides himself. It must be admitted that sentimental attachment to the old gardens induces the whole of the older Fellows to hope for the preservation and improvement of the old garden, but the vast mass of the new Fellows who have joined the Society within the last few years have no such feeling. They know nothing of its glorious past, and are indifferent to its present state. Still, among them are surely some who would, if it were explained to them, appreciate the necessity for an experimental garden, and a school of horticulture.

The allusion to new members induces us to mention that there was a net increase of 325 new Fellows elected last year; while the members elected for this present year, which is only a few weeks old, amount to 113, and this without the aid of band or balloons, fireworks, or frivolity. A "hall for horticulture" is, at the present moment, not a matter of practical politics. However desirable it may be, there is no chance of getting it just yet, even if the President's suggestion, that the guinea Fellows should double their subscriptions, were carried into effect. There must be central places in London more suitable for exhibitions than the present Drill Hall, which was only regarded as a makeshift, but which has proved a very serviceable one.

The subject of the awards of Medals, which the Council thinks has been carried on too lavishly, brought Mr. ALEXANDER DEAN and his brother, Mr. RICHARD DEAN, to their feet, and they represented the seething feeling of irritation at the new edict propounded by the Council. No doubt this matter can readily be adjusted, because clearly no slur was intended to be cast on the committees, whilst, on the other hand, there is no doubt that there is outside the Society a very prevalent feeling that the number of awards made is much too large, and that the reputation of the Society and the value of the awards would be much enhanced by a re-arrangement and simplification of the whole system of medal-giving.

In order that our readers may the better understand the position of affairs, it is necessary to give a slight account of what passed at the Floral and other Committees, held immediately prior to the general meeting:—

At the Floral Committee the paragraph in the Annual Report of the Council, circulated some days since, in which that body gave expression to the opinion that "there still appears to be a tendency to multiply unduly the awards recommended" by the various Committees, was, on the occasion of the meeting of the Committees on Tuesday last, followed by a letter from the Secretary, the Rev. W. WILKS, to the Chairmen of the Floral, Orchid, and Fruit Committees, in which the opinion of the Council was

reiterated, but in a fuller manner; the Council requiring that for the future the awards made to collections and groups should be determined by a Committee formed of three members of each Committee nominated by their respective Chairmen. Beyond the Chairman of the Floral Committee, who is a member of the Council, declaring that he thought the new arrangement a slur upon the committee—an opinion which was generally concurred in by a numerous-attended meeting, no discussion took place; but the chairman enforced his remarks by informing the committee that from the first meeting in January until the last in December, as many as 1248 entries were made of subjects which came before the committee. The awards made were as follows: 24 First-class Certificates, 209 Awards of Merit, 4 Cultural Commendations, and 4 Botanical Certificates. The number of Medals awarded during the same period was 266, and of this number 221 were awarded by the Floral Committee, and the remainder at the Temple Show by the judges. The Medals awarded by the Floral Committee to exhibits at the Drill Hall were 2 Gold, 18 Silver-gilt Floral, 18 Silver-gilt Banksian, 69 Silver Floral, 81 Silver Banksian, 7 Bronze Floral, and 26 Bronze Banksian.

The Fruit and Orchid Committees have followed practice of making Awards to collections of fruit and vegetables, or to groups of Orchids in a body. In the case of the Floral Committee a different course has been adopted; the chairman would nominate three or four members in his opinion best acquainted with the particular subjects staged, to act with himself as a jury, and they recommended the award of certain Medals.

In the course of his remarks on the letter received from the Council, the chairman expressed his conviction that no single Medal had been awarded that was not well deserved, and not till after the fullest consideration.

In the case of the Fruit Committee, an animated discussion also arose; and it must be admitted that a considerable majority of the members of both the Floral and Fruit Committees held that the new regulations put into force that day were, as the Chairman of the Floral Committee expressed it, a slight upon the Committee. The Orchid Committee took matters more philosophically, and whatever they felt they did not give much expression to it.

The San José Scale.

SOME of our readers may have already seen the following notice in the columns of the *Times*; but the matter is, or may be, of such importance to our fruit-growers, that we do not hesitate to reproduce it, and at the same time to publish a note from one of our valued American correspondents, who is in a specially good position to know what amount of injury is being effected:—

"BERLIN, February 3.—Considerable excitement has been caused for the last few days in German trading circles by an order prohibiting the importation of fresh American fruit. On January 30 the Customs officials at Emmerich received telegraphic instructions from the Minister of Finance to stop the importation of fresh fruit from America, and on the following day a similar order was issued by the Hamburg Senate. The reason for this step was stated to be the discovery of a species of plant-bug, the *Aspidiotus perniciosus*, or San José plant-bug, in a case of American Apples. Protests against this measure secured from the Hamburg Senate permission, first of all, for the further export of consignments to England, and subsequently for consignments of American Apples that had already reached Germany to be delivered to the addressees. To-day the subject occupied the attention of the Federal Council, which decided that 'the importation of fresh fruit is only forbidden when the same is discovered to contain the plant bug.' The prohibition does not extend to dried fruit. The importation of windfalls, packing material, and plants, is altogether forbidden."

The official *Reichsanzeiger* of Feb. 4 publishes the following, which we take from the *Daily News* :—

"The report published by the American Agricultural Department on the San José shield-louse gave rise to an official enquiry here into the circumstances under which fruit is imported from America. On January 29 Professor FRANK found on some Pears which were obtained from a consignment of Californian fruit, entered in the Hamburg free port, numerous living shield-lice, in a condition to propagate, which the Professor found to be absolutely identical with the

States, notably Oregon and British Columbia, have taken against it. The official organ then continues :—

"It is thus the unavoidable duty of the Government to give efficacious protection to the home fruit industry from the threatening danger of disease. Therefore is the importation of living plants and fresh plant-refuse entirely prohibited, and the importation of fruit and fruit-refuse prohibited, subject to the condition that at the port of entry of the said imports investigation of the consignment establishes the presence of the San José shield-louse."

the most severe and general fright which we have known for many years. The very mention of the San José scale is enough to put any horticultural assemblage into a fidget. The horticultural papers are full of talk about this insect ; almost every experiment station in the land has published some sort of an account of it ; and all the horticultural meetings, now in full blast throughout the States, show the most intense interest in any information which is offered on this subject. The San José scale is, in truth, doing serious damage in many widely-

FIG. 36.—PASSIFLORA EDULIS : FRUIT DEEP VIOLET. (SEE P. 102.)

true San José shield-louse. He consequently expressed the opinion that the home fruit cultivation was exposed to great and imminent danger by the importation of American fruit. A conference of other important specialists, and the reports of the Imperial Office of Health, confirmed this view in every point, and thus the necessity for prompt measures of protection was fully demonstrated."

The *Reichsanzeiger* goes on to describe in connection with the publication of the Washington Agricultural Bureau the extraordinary perniciousness of the San José shield-louse, as well as the measures which various American

The *Reichsanzeiger* shows by the example of the Phylloxera the danger of not adopting immediate measures of protection, while contrariwise the Colorado-beetle was kept out in time. The journal announces the regulations which are to be adopted internally to combat the shield-louse, and expresses the hope that the German fruit industry, on which a large community depends for its livelihood, may thus be protected from danger.

Our own correspondent writes from Vermont: "The fruit-growers of America are suffering

distributed localities ; and its spread has been so thorough and so insidious that tree planters are entirely bewildered, and know not where to look for protection. This scale was introduced into eastern nurseries from California. When it was first brought to the attention of entomologists a few years ago it did not seem to be widely distributed, nor to have done very great injury, and we were assured that it could not live over a very wide range of territory, especially northwards. Since that time, however, the successive limits set for it have been successively passed, and the pernicious insect has

come to light in the most unexpected places, and under the most disconcerting circumstances.

It is worse, both actually and prospectively, in the Southern States, but it has been found in Canada, and there is not a single fruit region on the continent for which immunity can now be promised with any confidence.

The scale is terribly omnivorous, feeding upon all sorts of fruit-trees and bushes, and attacking with equal appetite the deciduous trees and shrubs of the lawn. No practicable remedy has yet been found, except total destruction of the affected plants. A fungous parasite has been discovered, but its general applicability remains to be demonstrated. Several States have passed quarantine or inspection laws, but rather in desperation than in hope, for it really seems to be impossible to prevent the distribution of the insect without stopping entirely the distribution of plants. It is plainly to be seen, however, that the present excitement is out of proportion to the damage actually accomplished, and nobody would feel defrauded if the future should fail to justify it. At any rate, it is comfortable to hope that our fright will die away and leave us not so very much worse than we were before, as it did at the historical invasion of the Colorado Potato-beetle. *F. A. Waugh.*"

PASSIFLORA EDULIS.—The interest which has been shown of late in edible Passion-flowers, induces us to give an illustration (fig. 36) of the fruits of the true *P. edulis*, which we are enabled to do through the kindness of W. H. MAXWELL, Esq., of Munches. As will be seen, there ought to be no possibility of confusion with the edible fruits of the section quadrangularis, known by their square and winged stems and large leaves and fruits. The purple fruits of the present plant contain a highly perfumed pulp in the cells surrounding the seeds, and the flavour is as delicious as the perfume, but it is only by wide extension of meaning that it can be called edible. The plant is a native of South Brazil, where there are one or two nearly allied forms, some with yellow-coloured fruits, and nearly, if not quite as fragrant. The plant must be treated as a warm green-house or stove-plant, and a good look-out should be kept for mealy-bug. They may be planted out in the border, but require to be checked, as they ramble far and wide.

LINNEAN SOCIETY.—On the occasion of the meeting of this Society on Thursday, February 17, 1898, at 8 P.M., the following papers will be read:—1, "On the Genus *Arenaria*," by F. N. WILLIAMS, F.L.S., &c.; and 2, "On the Histology of the Salivary and other Glands of the Corlubridæ," by W. G. S. WEST.

BOTANICAL MAGAZINE.—The plants figured in the February number are:—

Richardia Elliottiana, Knight, tab. 7577; the largest species of the genus, with broad cordate leaves marked with white blotches, the spathe is rich yellow; see *Gard. Chron.*, July 30, 1892, p. 123.

Paphiopedilum (*Cypripedium*) *Chamberlainianum*, O'Brien, tab. 7578; *Gard. Chron.*, Feb. 20, 1892, fig. 34; native of Sumatra.

Daphne Blagayana, tab. 7579, Frazer; native of Styria; *Gard. Chron.*, Feb. 21, 1880, p. 245, fig. 47.

Dasystachys Drimiopsis, Baker, tab. 7580; a Liliaceous plant from tropical South-east Africa, with fibrous roots, short erect stems, broadly linear, recurved, glabrous leaves, spotted at the base and terminal crest, crowded racemes, flowers white with a short tube, and a 6-lobed limb about one-sixth inch.

Anemone vernalis, Linn., tab. 7581. An alpine species closely allied to *A. Pulsatilla*, which, though common in Scandinavia and in the Alps, does not occur in Britain. The flowers are creamy white with a central tuft of yellow anthers.

MEDALS.—We see that the French Society of "Chrysanthemists" (we have not the word yet) has

decided that medals shall be replaced by diplomas, so that more funds shall be available for the publication of the journal, *Le Chrysanthème*. A reduction in medals is very desirable nearer home, lest with each one, as now given, the honour be proportionately diminished!

STOCK-TAKING: JANUARY.—We take it to be a healthy symptom that the year's accounts open with an increased demand for articles of food and drink—dutiable or duty free; of course, in the matter of cereals the increase, as to great part is in money value, witness our averages of prices from week to week, and the Transatlantic "ring-keepers" are reaping their reward, we at home paying the piper on a high-priced loaf. In dutiable articles Tobacco shows a slight reduction, but work having now resumed throughout the engineering world this diminution will doubtless be reversed in next report. The increase on the imports foot up at £140,823. The falling off is to be found in Tobacco (£445), Chemicals, &c. (£61,705), raw materials for textiles (£3,264,315); and the major increases are to be found in food, duty free (£1,405,567); ditto., dutiable (£549,905); manufactured articles (£532,692), metals (£200,685), raw materials for sundry industries and manufactures (£337,058). The following excerpts have their usual value:—

IMPORTS.	1897.	1898.	Difference.
	£	£	£
Total value ...	89,775,668	39,916,491	+140,822
(A.) Articles of food and drink—duty free ...	11,847,359	13,252,926	+1,405,567
(B.) Articles of food and drink—dutiable ...	1,816,827	2,366,732	+549,905
Raw materials for textile manufactures ...	11,566,396	8,302,081	—3,264,315
Raw materials for sundry industries and manufactures ...	3,239,851	3,576,909	+337,058
(A.) Miscellaneous articles ...	1,180,270	1,376,612	+196,342
(B.) Parcel Post ..	120,275	130,881	+10,606

Of course, tariffs have to do with the falling-off in textile materials: more reason for opening up new fields for senders, as to which there is now some stir, and doubtless the desired end will be attained. By the way, in the matter of Hops, we have to note an increase of 47,741 cwt.; paper pulp has gone down 5834 tons; Clover and grass-seeds have gone up by 10,621 cwt.; cotton-seed is in excess over January, 1897, by 22,846 tons. Potatoes are especially conspicuous in the following table:—

IMPORTS.	1897.	1898.	Difference.
Fruits, raw:—			
Applesbush.	280,991	295,551	+14,560
Cherries
Plums	3	+3
Pears	2,458	3,060	+602
Grapes	1,381	1,001	—380
Unenumerated	36,630	56,441	+19,811
Onions	491,264	443,749	—47,515
Potatoescwt.	23,465	739,955	+716,490
Vegetables, raw, unenumeratedvalue	£64,017	£75,019	+£11,002

In the matter of Apples, our German friends have assumed that they have discovered a louse in the American Apples placed on their markets—they are now shut out, as was the pork some time since to keep from their fatherland the pest of trichinia, found in American pork, nowhere else! Possibly the loss to Germany may be a gain to us—at any rate, the supply has gone up, as will be seen by the table.

EXPORTS

now claim attention; and really the general unsettlement of things all over the world might well excuse a greater comparative deficit than that of £554,832. The total for the past month is £19,231,404, as against £19,786,236. The great decreases are to be found in yarns and textile fabrics, £502,480; in

machinery and millwork, £405,997; apparel, &c., £96,442; articles of food and drink, £10,475, &c.; whilst in the recorded increase we find metals, and articles manufactured therefrom, except machinery, £237,532; in raw materials of £134,956; all other articles, £67,967. The "raw materials," it may be noted, are made up in great part of coal, fuel, cinders, &c. We may be allowed to add that, so far as we can see, a more favourable record of trade may be reckoned on.

THE ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION.—The monthly meeting was held at Newport on Saturday last, Mr. J. H. PERKIN, Los Altos, Sandown, in the chair. Mr. J. HYGATE, gardener, The Briary, Cowes, gave an excellent address on "The Cultivation of Grapes in a Cool House."

THE AUTHOR'S CIRCULAR.—A new magazine "The Official Organ of the English School of Journalism" (295 Strand, W.C.), is admittedly devoted to the commercial side of literature, as a medium between writers and publishers. We hope it will find favour with all branches of the profession, and it will assuredly do good service to young authors if it persuade them not to flood the market with unsaleable wares, and to publishers if it can introduce them to really valuable contributors.

THE COST OF LONDON PARKS.—We take the following from the *Daily News*. Sir JOHN LUBBOCK has been trying to make a point against the London County Council on the ground of the cost of the parks. There is no more popular branch of the Council's work than its splendid management of the parks and open spaces under its care, and the cost of maintenance, calculated after Sir JOHN LUBBOCK'S manner, by the acre, is wonderfully cheap compared with the cost of some of the royal parks with which the County Council expenditure is comparable. For example, if you are going to divide your cost by your acreage, the sum voted in the Estimates for the maintenance of Hyde Park, St. James's Park, and the Green Park is £36,650, for a combined acreage is a little over 500, or between £73 or £74 an acre. The expenditure per acre complained of on the part of the County Council is £28. The absurdity of a calculation by the acre in the case of the parks is shown by the comparison of the cost of the royal parks above-mentioned with Richmond Park, which costs the county £2,250, but is of so large an acreage that, measured in this way, its cost is a little less than £1 the acre. The County Council's park expenditure includes the wages of constables who patrol the commons and open spaces for the protection of the public and their children, and many other charges which have little to do with acreage.

AUNT KATE'S GARDENING BOOK.—This handbook (published at the *People's Journal* Office, Dundee), offers, at the low price of a penny, forty pages of information concerning the cultivation and exhibiting of plants. It is illustrated, and the utility of the directions given may be depended on.

PUBLICATIONS RECEIVED.—*May's Practical Methods to Ensure Relief and Cure without Drugs*. This is the abbreviated title of a book on home-doctoring, by E. & B. MAY, the wisest direction being to lose no time in sending for a qualified medical man, and sedulously to avoid quack remedies, however insidiously advertised.—From the New York Agricultural Experiment Station come the following Bulletins: Popular edition of No. 125 on *Tomato Forcing*; No. 129, *Report of Analyses of Commercial Fertilisers for the Spring of 1897*, L. Van Slyke. No. 130, *A Bacterial Disease of Sweet Corn*, F. C. Stewart; No. 131, *Results with Oak Smut in 1897*, C. P. Close; No. 132, *Source of Milk Fat*, W. H. Jordan and C. G. Jenter; *Spraying in 1897 to prevent Gooseberry Mildew*, C. P. Close.—From the U. S. Department of Agriculture: *List of Publications relating to edible and poisonous Mushrooms*, J. A. Clark; *Farmers' Bulletin*, No. 68, *Black Rot of the Cabbage*, E. F. Smith.—From the University of Vermont, Agricultural Station: *Bulletin* 62 (Jan. 1898)

Home-grown Grapes in Vermont, F. A. Waugh; No 61, *Hardy Apples for Cold Climates*, F. A. Waugh.—*Botanical Magazine* (Tokyo) Dec. 20, 1897.—*Native Guano* (Native Guano Co., Blackfriars, E.C.)—*Wiener Illustrirte Garten Zeitung*, January, 1898.—*Bulletino della Società Botanica Italiana*, No. 5, 6, and 7, for October, November and December, 1897.—*Nuovo Giornale Botanico Italiano*, January, 1898.

PLANT PORTRAITS.

ECHEMEA CYLINDRATA, Lindman, Metz, in *Gartenflora*, t. 1447, February.

HYACINTH "HADYN", single, violet-coloured flower, *Florilegium Haarlemense*, t. xiii.

LAVATERA TRIMESTRIS, *Garden*, January 22.

NARCISSUS: 1, *Pseudo-Narcissus*, double flower, Van Sion; 2, *N. incomparabilis*, fl. pl. orange-phoenix; 3, *N. incomparabilis*, sulphur-phoenix; 4, *Sulphur Crown*, *Florilegium Haarlemense*, t. xv.

TREE-PEONY, Madame Gustave Croux, rose-pink, *Revue Horticole*, February 1.

TULIPS: 1, Duchess of Parma, red with yellow margin; 2, Thomas Moore (rendered *Morus*!), pinkish-buff; and 3, Ophir d'Or, yellow, *Florilegium Haarlemense*, t. xiv.

MARKET GARDENING.

PREPARATION OF THE GROUND IN THE NEW HOUSES.

The next work needing to be done is the preparation of the ground in the several glasshouses for the reception of the respective crops. The houses intended for Vines, Peaches, and Tomatos (exclusively) should be trenched between 18 inches and 24 inches deep, according to the natural depth of the soil, breaking-up the bottom of the respective trenches with a digging-fork, and laying thereon about 3 inches thick of good manure. Cover this with the top-spit, which, if lumpy, should be broken with a spade in doing the work, following with another layer of dung, the remaining portion of good soil being placed on the top, and so on, until the work is done. The houses allotted for Peaches and Nectarines should be planted as soon as the houses and ground are ready. Indeed, for that matter, and in order to save time, the trees may be planted—say 15 feet apart—before the borders are double dug or trenched by simply opening good-sized holes, breaking up the bottom spit, manuring, &c., as recommended above, and planting the trees therein; covering the roots with the natural soil enriched and well mixed with, say, one-third or one-fourth, according to circumstances, of short manure. In completing the planting of each tree, take hold of the stem with the hands, and give a couple of short pulls, or rather shakes, in an upward direction, in order to let the soil well in among the roots. Early Alexander, Amsden June, and Hale's Early Peaches, and Rivers' Early and Lord Napier Nectarines are capital varieties to grow, the fruits being extra early, good size (when well grown), fine colour and full of flavour.

Tomatos planted in rows from 18 inches to 24 in. apart, and running from the central pathway to the brickwork on either side, and set at 1 foot from plant to plant in the row about a month or six weeks hence, will, in themselves, yield satisfactory returns for the houses thus planted for the first two or three years, by which time the Peach and Nectarine trees will have fully established themselves and completely covered the trellises, extending over the greater part of the 14 or 15 feet rafters with fruit-bearing wood, the trees having been, as a matter of course, trained on the "extension system," as advocated from time to time in the *Gardeners' Chronicle*. Tomatos may be planted in the same way in vineries, and for about the same period of time, as in the case of Peach-houses. Of course, the number of plants grown in each row will considerably diminish each succeeding year, as also the weight of the crop obtained therefrom, by reason of the increased shade cast over the ground-space by the Vines and Peach-trees. The lateral and leaf-growths must be kept persistently thinned, that is, the side-shoots must be pinched hard back to the main stem, and the leaves cut back to within one or two pairs of leaflets during the whole fruiting stage of the plant's growth, so as to concentrate all the strength of the individual plants into the production of flowers and fruit.

FIG. 37.—SAN JOSÉ SCALE ON Californian Pear, moderately infested: natural size.

FIG. 38.—SAN JOSÉ SCALE. Female scale enlarged.

FIG. 39.—SAN JOSÉ SCALE. Adult Female, containing young: greatly enlarged.

FIG. 40.—SAN JOSÉ SCALE. Young Larvæ: greatly enlarged.

These figures are taken from the Bulletin No. 121 of the Michigan Agricultural Experiment Station. See p. 100.

In the case of Vines, when they have made about 3 feet of growth above the rims of pots, they should be planted about 2½ feet apart in the border at from 9 inches to 1 foot from the division-walls or piers, making the soil firm about them in planting. It is much better to let the young Vines attain to a height of 3 or 4 feet before being transplanted than to plant them earlier, inasmuch as the tops of the young canes are at that length (3 or 4 feet) brought well up to within a few inches of the glass.

A house intended for Cucumbers need only have a trench taken out about 2 feet wide and 9 inches deep the entire length of both sides, keeping close to the piers or division-walls, as the case may be. Break up the bottom soil in each trench with a digging-fork, then lay on a good coating of well-rotted manure, and cover this lightly with some of the best soil excavated from the said trenches. This done, insert sticks long enough to reach the first wire in the trellis (to which they should be secured) at 2 feet asunder along the centre of each trench, and at these several points make hillocks, each consisting of about 1 bushel of compost composed of three parts best available mould and two parts good manure. On each of these hillocks put one Cucumber plant as soon as the soil has become warm. Press the soil moderately firm round the roots in planting, and afterwards afford tepid water to settle the soil about the roots. Rollisson's Telegraph (true), Carter's Model, Webb's Bountiful, and Rochford's Market are excellent ones to grow for the supply of the market. H. W. Ward, Rayleigh.

FOREIGN CORRESPONDENCE.

SOLANUM WENDLANDI.

This beautiful climber flowered splendidly in Stuttgart, for the first time in the open, in the nursery of Mr. Wm. Pfitzer. Planted out at the end of May, in a warm and sunny position, and in a nourishing not too heavy soil, against the wall at the end of a greenhouse, it soon covered all the available space on the trellis, which had to be extended. It bloomed throughout July and August, notwithstanding the unusually rainy and inclement weather, which prevented the *Daturas* (*Brugmansias*) from displaying their full beauty. After flowering, the *Solanum* was in October cut well back and planted in a tub, and then placed in a warm greenhouse, in order to become well established before the winter. After furnishing material for propagation in the spring, the process will be repeated.

These remarks may perhaps lead to the more extensive planting out of this and similar plants in the south of England and in other warm and sheltered localities. Beside the above-mentioned *Daturas*, of which D. Knighti, fl.-pl., is periodically covered with its fine white flowers, various other sub-tropical plants, generally cultivated in pots or greenhouses, are planted out. *Hibiscus rosachinensis* and its varieties, for instance, given a suitable soil and a somewhat sheltered position, will bloom beautifully, daily producing fresh flowers. H. R. W.

VARIORUM.

TOBACCO-DUST AS A REMEDY FOR SLUGS.—Observing the note on p. 30, headed, "To destroy Snails," I may say that about twenty years ago a Tobacco importing company in Liverpool—I think it was the Richmond Tobacco Company—tried the experiment of grinding up the refuse tobacco, like coarse snuff, and selling it at a very cheap rate, mixed with lime to satisfy the Excise, as a remedy against insects in gardens. I think the wholesale price was only 9s. per cwt. For several years I used it, with very good results, especially against slugs; but the firm gave up making it, not meeting, as they told me, with a sufficient demand, and I have not been able to get it since. C. Wolley Dod, Edge Hall, Malpas.

HOME CORRESPONDENCE.

THE GARDEN CHARITIES, CANVASSING.—A friend sends me for inspection no fewer than six post cards he had received, asking for votes for one Orphan Fund candidate. If others were appealed to in the same ratio, what a wasteful, wanton expenditure does this represent. I make it a rule never to vote for any candidate thus canvassed for, to place all candidates, whether they have influential backers or not, on the same footing; canvassing on behalf of any candidate should immediately be followed by disqualification. With respect to the Gardeners' Benevolent, Mr. Crump urges me to use my influence to secure more gardener subscribers. What is the good of importuning anyone in the face of such a rebuff to subscribers as that given at the recent election? Is there anyone who is satisfied with the results? Until the executive alters the rules so that none but subscribers of at least five years, or their widows, shall be eligible to be candidates for the pensions, can it be expected that gardeners generally, to most of whom a guinea is a great consideration, will become subscribers. A good deal has been made of certain unsigned papers being returned at the last election; were these papers sent to the secretary direct or to some member of the Committee or active promoter of some candidate who had importuned for them? None the less, were all voting-papers numbered as issued, the number on each corresponding with the secretary's list, not a paper need be signed; and a real ballot would be instituted. Nothing is easier, and would be opposed only by those who may wish (as they should not) to ascertain how So-and-So voted. *A. D.*

THE FLORAL COMMITTEE AND ITS AWARDS.—That the Council of the Royal Horticultural Society succeeded in irritating the members of its committees, there can be no doubt; and vigorous expression was given to the dislike generally entertained to the new regulations—and it also found utterance at the Annual General Meeting, held on Tuesday last. The Council appears desirous to restrict the number of awards made to new plants, flowers, fruits, and vegetables, or such of them as may appear to call for recognition. Occasionally, an old subject is produced in exceptionally fine character, something that possesses great merit, but which has practically fallen out of general cultivation, and an award is made to it as an appreciation of its value. It should be borne in mind that at the present time the work of hybridising, crossing, and selecting plants is being actively pursued; raisers and exhibitors multiply, and there is a constantly increasing number of novelties seen at shows and meetings, more especially during the summer months. It should be remembered that the Floral Committee is a large body—too large in some respects; the members vary in their partialities for certain flowers, and when something is presented to them which they conceive to surpass anything they are acquainted with, they are desirous that it should be recognised. A bare majority suffices to carry an Award; and in the case of some special subject, known intimately to only a very few, but a small majority suffices. Comparatively few subjects find unanimous recognition from the members of the committee present, and when such an Award is made, the object shows the highest possible development. There are at times sharp divisions, the committees being almost equally divided, and a vote or two more on one side than the other carries the day. Whether a stated majority of the committee be required to carry an Award, is perhaps both doubtful and inexpedient in practice under the present methods of appointing to the committees. In this respect there is much room for improvement. *R. D.*

MORISIA HYPOGÆA.—For the information of readers who may wish to add to their stock of this beautiful little alpine plant, spoken of by your correspondent, "E. S., Woking," on p. 89, I may say that in addition to the methods of increase by seed or cuttings it can be readily propagated by root-cuttings. A plant carefully lifted will yield a good many of these. My method is to cut them into lengths of an inch, which I place in pots of sandy soil, keeping the upper part of the cutting on a level with the surface of the soil, and placing the pot in a greenhouse. I prefer the month of March for making the cuttings. In a rather dry soil the *Morisia* does not flower so freely as in one with more moisture, and in this garden the flowering period is shorter than it is further inland. Do any of your readers know if this plant ripens its seeds in our climate? I am doubtful if it even produces any;

and on reference to-day to an article written by an expert on hardy flowers, which appeared in a contemporary (*The Garden*) in 1891, I observe that the writer says:—"It is said to ripen seed, but plants which flowered freely with me have not produced any; at any rate, I have failed to find it, although I have carefully scraped the soil away from the roots." I have grown it here for about six years, and have been unable to find seeds. It is a beautiful little plant, with leaves glossy as with varnish, and flowers of a clear yellow hue. *S. Arnott, Carsethorn, Dnm-fries, N.B.*

—All lovers of alpine ought to be deeply indebted to "E. S., Woking," for bringing this lovely little species under notice (p. 89), for it is certainly well worthy of a place in every collection. For brightening up the rock-garden it has few equals; and considering how accommodating it is, and how easily it may be increased, it ought to be more freely grown. I should like to know if it is known in gardens under any other name [No.], as I find no mention of it in *Nicholson's Dictionary*, while one very seldom sees it catalogued. *W. J., Pife.*

ABNORMAL FLOWERING OF CALANTHE VEITCHI.—We have had two bulbs of the above-named, grown singly in separate pots here, throwing two flower-spikes, and flowering at the same time, viz., one at the bottom of the bulb, whence the flower-spike naturally comes, and the second spike breaking through the top of the bulb; the spike at the top of the bulb showed seven buds, one carrying five perfect flowers, and the other four. I shall be pleased to know if any readers of the *Gardeners' Chronicle* has had a similar experience, and if it is unusual. *W. R., Cadlands.*

EXPORTATION OF SEEDS AND PLANTS.—The season is now at hand when many nurserymen, including myself, will be receiving numerous small orders from Germany for plants such as Dahlias, &c. The cost of sending small lots by rail and steamer is expensive and very inconvenient compared with the parcel-post; but here we are handicapped by the postal authorities prohibiting plants with roots being sent by parcel-post. The reason for this regulation is difficult to understand, seeing that we do not suffer from Phylloxera to any extent in Great Britain. Could not something be done by our traders to try and get rid of such a grievous hindrance to trade? And I, for one, and I have no doubt a great many readers of the *Gardeners' Chronicle*, would be glad to elicit the opinions of others in regard to this matter. *John Green, Dereham.*

MORE ABOUT FREESIAS.—I herewith enclose for your inspection some cut scapes of Freesias. One spike with eleven individual flowers, one with ten, others with nine and eight. I have a large number of scapes with eight and nine flowers. Under ordinary cultivation, the number of individual flowers on a scape of *refracta alba* will average from three to seven; and I have many with two and three laterals averaging from twenty to thirty flowers from one bulb. My object in writing is to ascertain if any readers of the *Gard. Chron.* have ever produced a larger number of individual flowers from one bulb than eleven on a scape? I notice in bulb catalogues that eight blossoms are shown in illustrations; nine flowers are all I can produce on *Freesia refracta alba*, and eleven on *F. Leichtlini* major, under good cultivation. If more has been produced on these varieties, I have still something to learn of their cultivation. My treatment is similar to that recommended by Mr. Swan in the *Gardeners' Chronicle* for January 1 of this year, which I read with much interest. *S. Kerry, Hatfield Peverel, Essex.*

PASSIFLORA ALATA.—I was much interested in the remarks made by D. T. Fish in your copy of January 22. It would appear to me that as Mr. Fish so constantly and regularly fruited the form he describes as *P. edulis*, and that such fruits were served at table and eaten with avidity, or as he says, "few fruits were more greedily devoured," they must have been the same as those figured—and which I have grown as *P. alata*. I have had four names given me as the correct one, viz., *P. quadrangularis*, *P. edulis*, *P. macrocarpa*, and lastly, *P. alata*; the latter it now seems to me to be the correct one. Mr. Fish complains of the size of the figure of leaf on page 449, Dec. 25. I am surprised myself at the diminutive form, measuring $3\frac{1}{4}$ inches in breadth, by 4 inches in length, minus the leaf-stalk, and it must have been reduced in the engraving [the leaf was purposely reduced to fit our columns though, unfortunately, this was not stated. Ed.]. I now send four leaves which measure $7\frac{3}{4}$ and 8 inches in breadth, and

10 inches in length, minus the leaf-stalk. These leaves were taken from a plant that still remains in the old pine stove here, and since Dec. 11 has had no fire-heat at all. In fact from that date no attention whatever has been given to it. A spell of frosty weather, however, would now soon cause it to shrivel and die away. *W. Swan, Bystock.*

PASSIFLORA EDULIS.—I think Mr. D. T. Fish is on fairly safe ground in his advocacy of *Passiflora edulis*; whether the one usually grown be the species or a garden variety, I do not pretend to say; though the editorial note, "Something to suck, but little or nothing to eat," probably holds good. I never tasted a fruit grown under glass. In places in latitude 33° S., I have seen the plants flourishing without protection, and subjected to 7° or 8° of frost without injury, which may bear out Mr. Fish's remark about cool treatment. *Passiflora quadrangularis* would not succeed under like conditions. To be appreciated, the fruit must ripen on the plant, and be eaten immediately after removal, as it deteriorates within a few hours. To this fact may be attributed the frequent adverse opinions of those who have partaken of tropical fruits, an instance of which occurred in the *Gardeners' Chronicle* for November 6 last, when noticing the Mangosteen. Again, the dried Litchie fruits, which reach our markets, convey no idea of what the fresh fruit is like when freshly gathered, being as little like the latter as a Muscatel Raisin is to a well-ripened Muscat of Alexandria direct from the Vine. Persimmons, or Japanese Date-Plums, have lately been noticed, the taste for which will in many cases have to be acquired; but speaking generally, the Passion-fruit, Litchie, and Mangosteen, are agreeable to our tastes generally. Unlike the Banana, I do not think that any of the fruits I have noticed will endure the adverse conditions of a long sea voyage, and it must be always admitted that fruit consumed in a ripe state as taken from the tree is to be preferred. *C. B.*

SOPHRONITIS GRANDIFLORA.—One of the finest examples of this plant is to be seen in the gardens of J. C. Waterhouse, Esq., Collar House, Macclesfield. The plant is contained in a cork basket, 9 by 6 in., and 2 inches deep, and carries sixty-six fully developed flowers. There are numbers of smaller but equally healthy and well-flowered plants under Mr. Hall's care. *J. Robson.*

THE GREEN COLOUR IN FLOWERS OF VON SION DAFFODILS.—This has been a much debated subject for years through the *Gardeners' Chronicle*. This being one of the earliest of seasons of which we have any record so far as flowers are concerned, thousands are in full show here, and such yellow, solid flowers I have never before noticed. Will some better judges than myself explain this? I have my own opinion about green blooms. I should say such early growth and bloom should make the bulbs of great value for forcing next year. *Wm. Baylor Hartland, Ard-Cairn, Cork, Feb. 8.*

PRUNING YOUNG STANDARD APPLE-TREES.—My experience with regard to young Apple-trees, after several years close observation, leads me to say that if you wish to ruin them follow up the method practised by your correspondent, Mr. Kettle. For if there is any one thing that will cripple a young tree, it is to overcrop it. Half a sieveful of good fruit, as stated by Mr. Kettle, from a tree three years old from the bud is a very heavy crop indeed, and I greatly fear that as time goes on he will find that instead of his trees making good specimens in a short time, just the reverse will occur; a tree once overtaxed when young, takes years to recover its vigour. What are we then to do with young trees received from a nursery furnished with 5 to 7 shoots 2 feet in length, are we to allow these to go unpruned? Most practical men know that if these shoots be left at full length, fruit in quantity will be borne the following year; and if these fruits are allowed to remain their weight will drag down the shoots, and if not supported perhaps some of them will be torn off at the base—and further, these shoots will fail to produce a free growth the following year, and frequently a fruit-bud will form at the points, and they will fail to thicken. I tried the practice once as an experiment, and had after a couple of years' to shorten them back in order to force a fresh growth, so that instead of gaining I lost time. Young fruit trees should be well planted, and in order to obtain an evenly-balanced crown, shorten the leading shoots more or less, according to their strength, cutting back the small laterals to within 2 inches of the main shoots, or removing them in some cases entirely, and taking care when shortening

the leaders to cut to a bud pointing in the direction in which the next growth is needed. Leading shoots, if of normal strength, I usually leave about 12 inches in length, weak ones at less than that. The knife should be carefully used for the first few years, and when the branches have acquired strength to bear fruit, let the crop be heavy or light, in accordance with the vigour of the trees, but do not overcrop any young tree that inclines to bear fruit before it has sufficient strength to bear and grow freely. In reference to Mr. Ward's advice, I consider his teaching is sound and practical. *H. Markham, Northdown, Margate.*

WATER-BOUQUETS.—The note by "A. G. B." on these very interesting objects induces me to say that with one exception, at Farnham, I had never seen them elsewhere exhibited except at Basingstoke, where, a few years since, if not still, they constituted a very pretty and an attractive class. The method of securing the stems of the bunch of flowers to be immersed in water to the dish on which stood, varies in practice. No doubt, where stout glass-dishes, some 9 or 10 inches in diameter, each having in the centre a small knob or loop to which the bunch could be securely tied, it would be the simplest way; then, in any case, whatever method or weight be used, a few flakes of nice moss secured to the dish covers the lower portion of the stems. At Basingstoke, where the bouquets were first introduced by a gentleman, whose name I forget, some used a lump of clay to secure the flowers to the dish, others a piece of lead; whatever was used, however, was always neatly covered. The bunch of flowers should not be large, be neatly grouped, and thinly arranged. Single flowers seem to be best. When immersed the water materially magnifies them. The glass-shade or cover should be fairly stout, as the body of water contained, when the flowers are properly immersed, exercises material lateral pressure. The shade or cover should not press upon the flowers, and in placing it over them in a large tub or tankful of clear water, sideways, no air must be allowed to enter. As "A. G. B." has mentioned, when the glass-cover is in place, the whole can be lifted out of the water, be stood on a tray to run dry, and then be more pleasing as an ornament if stood upon an elevated glass dessert-stand. *A. D.*

VEGETABLES.

EGG - PLANT.

THOSE persons who like the fruit of this plant as prepared on the Continent, should sow seeds next month and in March on a hot-bed, and prick out the seedlings on another hot-bed in about a month after germination has taken place. They might be planted out in May at the foot of a south wall, in very warm parts of this country, but are better for receiving glass protection. They will not do under the shade of Vines or Peaches, and should have a pit or house to themselves, or at least a cold frame. Here it is advisable to grow only the early-ripening varieties, as Early Purple Dwarf, and Early Long Purple. There are many varieties but these are too late in ripening to be suitable for cultivation in this country. The plant likes a fairly adhesive, not over-rich soil, and to be potted firmly. Having set a crop of fruit, the later blooms should be removed, and manure-water occasionally applied if the soil is permeated in every part with roots.

GOURDS.

Beyond the two or three varieties of Cucurbita Pepo (Vegetable Marrow), we are singularly deficient in our appreciation of the food to be found in many of the Gourd family, and even those we have got accustomed to eating, are partaken of in their very least nutritive state of development. What sustenance can be found in an unripe Vegetable Marrow? As an adjunct to a well loaded dinner table it is an allowable vegetable, but on the scantily provided poor man's table, it should have no place. With Pumpkins or Gourds it is very different. These are not considered edible until they are quite ripe, in which condition their nutritive value is greatly increased, and they are capable of being kept sound throughout the winter, and even after being cut open they remain in good condition for several weeks. Moreover the large seeds of some of the varieties are as pleasant eating when stripped of the outer cover-

ing as filberts. There are of Pumpkins, the Mammoth, the Etampes, the Boulogne Gray, the Warded Marrow. The Turks' Cap, Canada Crook Neck, and of Marrows to be eaten when ripe the Patagonian Squash, and Bush or Crook Neck, and Custard Seeds should be sown in March, and the plants put out under hand-lights in May, the lights being kept over the plants so long as the weather is cool.

NEW INVENTION.

LAWTON'S PATENT POT-SUSPENDING CLIP.

THIS simple invention will be found useful in a variety of ways, amongst which may be specialised the suspension of plants in pots for conservatory or other decorations, either against a wall or from the roof. To the Orchid-grower it is invaluable, as by its use a few moments only are required to make any pot or pan ready for suspension, without any of the usual difficulties and unsightliness caused by the binding round of string, wire, &c. The clips can

FIG. 41.—SUSPENDING FLOWER-POT CLIP.

with equal facility be used for suspending cut flowers in vases, &c. (it may even be used for an ordinary tumbler), thus getting over one of the greatest difficulties in floral decorations for walls. It also makes an excellent substitute for the wire holdfasts used for holding plates, plaques, &c., against a wall, and has the advantage of being considerably less in cost.

The inventor has had these clips in use for some considerable time, and can guarantee their efficacy and durability. The sole agent for the sale of these suspenders is Mr. J. George, Horticultural Sundries-man, 14, Redgrave Road, Putney, S.W.

MARKET NOTES.

APPLE CROP OF TASMANIA.

WE have received from the Agent-General, Tasmania, the information that the number of cases of fruit to be sent for the home market will be fewer than on previous occasions. There may be three reasons for this—the crop may promise to be a short one, it may pay best to send only a supply of the very finest samples, or if the crop in Australia threatens to be a short one, then it will require to be supplemented by supplies from Hobart.

NURSERY NOTES.

MESSRS. CARTERS' PRIMULAS.

AN extensive and interesting display of Chinese Primulas may be seen at the present time in the nursery that Messrs. Carter & Co. have at Forest Hill. Dropping in on a bright bleak morning, a day or two since, in response to an invitation, we had the pleasure to carefully inspect the entire collection, and to contrast or compare the peculiarities of the numerous varieties. Some idea of the show these Primroses make may be obtained from the fact that seven of the long-span roofed houses are more or less filled with them, which we were told numbered upwards of 7000. The condition of the plants is surprising, as they have been all produced from seed sown towards the end of last July, which appears to us rather late in the season. They were only put into the pots in which they flower about two months ago—in December—and upon turning out a plant from a 5 or 6-inch pot, the roots are seen to be just gripping the soil loosely; yet every one is producing an abundance of bloom. We may have seen sturdier habited batches of plants at establishments surrounded by purer atmosphere than is possible in London urban districts, but seeing that the plants at Forest Hill are from seed sown but six months ago, and have been grown in the locality mentioned—well, they would cause many a visitor some reflection.

The varieties are numerous, and some of them are very much like each other, the difference being one of tint only. They are arranged in batches, and from so many plants, the average colour, habit, or size of any variety is easily obtained.

Of the single-flowered strains, the purest white appears to be Elaine, an erect variety, with dainty flowers of moderate size. In general effect, however, it is excelled by Queen, a handsome Fern-leaved variety with profuse and bold flowers that open white and become very pale blush afterwards. There is a Lilac Queen too, the shade being somewhat novel, and a Rose Queen, but this is much too light in colour for such a designation, being barely a pink. We saw no approach to a yellow Primula at Messrs. Carters', but the colour that usually stands for blue in these plants, is seen in double and single types. The single one created quite a distinct effect. Princess May is a giant form, and probably the largest flowered of all the Primulas at Forest Hill; sturdy in habit, there is substance in leaves and flowers, and the truss of bloom is a strong one, the colour of the flowers being pink and white, and giving an effect of blush pink or rose. Of the bright colours, there are Magenta, Vermilion, and Carter's Scarlet. All of these are very good, in colour especially. From the first named, however, an improved strain has been obtained, and from the few plants of this to be seen, it promises to be valuable. Vermilion is good, and Carters' Scarlet being side by side with it, the difference is well shown. There were good batches of either, and the Scarlet being one of the earlier varieties to flower, had set, and was already swelling a good number of seeds. Ruby, on the contrary, is one of the latest, and its first ruby-red blossoms, with bright eyes, were at their best above the Fern-like foliage—probably the only batch that the "polleniser" had not been over with his brush. Carmine is a variety excelled by few; it produces large, handsome, fringed flowers, and robust foliage. Venus has flaked flowers, and may be had with plain or Fern-like foliage. Amongst other single forms, we may mention one known as Salmon, a pretty tint of salmon-rose colour.

Messrs. Carters' double Primulas consist of semi-double sorts that are propagated by seed, and come true by this method—a type that has ousted to a large extent the really double Primulas that must be propagated by cuttings, and are found somewhat difficult of cultivation in gardens. Snowflake is one of the earliest of these to flower, and is a capital variety for furnishing blooms for cutting. It has very small foliage, and pale, slender petioles, the flowers open blush, but soon become white. The

Princess of Wales is also nearly white, but the flowers are flaked a little with rose. In Prince of Wales, an early rose-coloured double, we noticed a very charming flower that seemed to possess several shades of colour, and the margins of the petals are prettily crimped. Aurora has moderately small flowers, but the variety is exceptionally free; the blooms are salmon-pink. Blue Rosette has much the same tint as the single-flowered one already noticed. Vivid is only less bright than Double Scarlet. The former has a shade of carmine in it, but the latter is a truer scarlet. Lilac Queen is a shade of some novelty, approaching deep lilac.

We were much interested in a batch of plants of

THE "BOUQUET" PRIMULA, a "variation," in which the calyx of the flower is foliaceous to an extent that it surrounds each flower, and forms a perfect button-hole, as it were. Another singular circumstance in the habit of this plant is that previous to the usual central truss of bloom developing, there are produced from the base around the spike of the truss [but not from it] five blooms, upon solitary stems, 3 inches high, the calyx in these being extremely foliaceous. In the truss there is a foliaceous development of the bracts and of the calyx under each bloom, but not so marked as in the early "basal" flowers. The blooms are white when first open, but become blush afterwards. Independently of the flowers, the plants are exceedingly distinct in appearance; the leaves are of great substance, and crimped and cut unusually. The plants we saw had been raised from seeds, and there was a fairly good batch; but seeds may not be bought yet, and it seems uncertain when it may be catalogued, or even if it will not have to be propagated by cuttings. It seeds very little, and the effect of using repeatedly pollen from normal varieties might cause the reversion of the type altogether.

A splendid batch of Cineraria plants was observed that will soon bloom.

SOCIETIES.

ROYAL HORTICULTURAL.

FEBRUARY 8.—The second meeting of the committees of this Society for the present year was held on Tuesday last in the Drill Hall, James Street, Westminster. There was a moderate display, not quite so much in extent as is sometimes the case on the occasion of the Annual General Meeting of the Society, when an augmented number of Fellows in attendance is comparatively certain. Orchids, however, were rather more numerous than they have been at several recent meetings, and there were large and excellent collections of Chinese Primulas. An exhibit of Freesias in pots from an amateur (the Hon. H. C. LEGGE) were well deserving of praise. The comparative mildness of the weather enabled the cultivators of hardy plants to show some of their earliest treasures from the open ground, and others in pots or pans that have been protected in cold-pits. Other interesting exhibits of miscellaneous description are remarked upon below. There was not much fruit staged, but in the "flavour" classes the competition was somewhat remarkable, and many good Apples and Pears were exhibited. The Fruit Committee granted two First-class Certificates, one to an Apple, previously distinguished by an Award of Merit, and the other to a Pear that has been in cultivation many years. Considerable irritation was caused among the various committees by an intimation from the Council that it was proposed to invest the privilege of granting Medals to meritorious exhibits of plants, flowers, or fruit, that formerly had belonged to each committee, in a body composed of several gentlemen to be deputed by each committee, and this body (not the whole committee) would award Medals to Orchids, and other plants, fruits, or such exhibits as were thought worthy of reward. The intention of the Council was good, it being none other than to lessen the number of the awards, and thus increase their comparative value. The means taken, however, were not judicious or desirable, and at the Annual Meeting, Sir Trevor Lawrence, in answer to spokesmen from the Floral and the Fruit Committees, was understood to say that he would recommend the Council to rescind the proposal, and suggest that the several committees select two or three of their members to award honours to collections, whilst the rest were engaged with novelties—a practice that has obtained in the Floral Committee for some time past. Thus, a fruit-grower will not be called upon to appraise the value of a group of Orchids, or vice versa, and the sensibilities of the committee-men will be respected.

Floral Committee.

Present: W. Marshall, Esq., Chairman; and Messrs. John Fraser, Owen Thomas, J. T. Bennet-Poë, H. B. May, R. Dean, J. H. Fitt, Geo. Stevens, W. Howe, Jas. Hudson, J. Jennings, C. J. Salter, R. B. Lowe, H. Selfe-Leonard, J. Fraser, W. Bain, Chas. Jeffries, J. D. Pawle, Geo. Gordon, Chas. E. Shea, Jas. Walker, J. W. Barr, E. T. Cook, H. J. Cutbush, H. Turner, Chas. E. Pearson, H. J. Jones, and Geo. Paul.

Messrs. R. & G. CUTHBERT, Southgate, exhibited a collection of varieties of Crocuses in pots; also Scilla sibirica and S. s. alba, and a number of straw-coloured Roman Hyacinths.

Bougainvillea spectabilis, from Her Grace the Duchess of CLEVELAND, Battle Abbey (gr., Mr. W. Camm), created a sensation. It was shown as three long and beautiful sprays, literally smothered with flowers the whole length, and the colour was irresistibly attractive. This species less commonly flowers than B. glabra, but the colour of the flower is more telling than that one. The orange-flowered Bignonia venusta was shown in sprays from the same establishment.

A most commendable exhibit of Freesias in pots was made by Major Hon. H. C. LEGGE, Fulmer, Slough (gr., Mr. J. G. Mowbray). This fragrant exhibit consisted of about 100 5 and 6-inch pots, and all of them contributing a good share of blooms.

Messrs. JAS. VEITCH & SONS (Ld.), King's Road, Chelsea, contributed such Chinese Primulas that could hardly have presented better cultural effect, or greater excellence of strain. In the double and single flowered sorts, the quality was good, the plants possessing healthy, well developed foliage, and the flowers being remarkable for size, strength, and brilliant colouring. The double-flowered varieties included Rose, Salmon, Lilac, Crimson, Blue, and White, each distinct in batches of a dozen or more plants. Then there were singles, Chelsea Blue, Rose, Fringed Red, Fern-leaf Lilac, Gigantic Blue, New Salmon (very fine), Fringed White, Chelsea Crimson, Gigantic White, Fern-leaf Blue, Gigantic Rose, and Gigantic Red. A few plants of a white-coloured variety of Stellata in the centre of the group were as pretty as showy, and a few "Blue" Primroses were shown from the open ground, where they had been slightly protected.

One half of one of the long tables was well filled with excellent Chinese Primulas, from Messrs. H. CANNELL & SONS, Swanley, an exhibit that created more effect than any other in the hall. The ordinary florist's Primulas were capably represented by such varieties as Cannell's White, White Swan, Cannell's Red, Swanley Blue, Duchess of Fife (pink), Dr. Nansen (white), Cannell's Pink, Swanley Giant (fine rose), Her Majesty (white), Glow-worm (red), Victory very bright rich magenta, White Perfection, and others, all single-flowered varieties. The "Lady" strain, or varieties of P. stellata, hort., was shown, and several new varieties, obtained from crossing the "Lady" with ordinary florists' varieties, were capital. The best of these was Mrs. R. W. Cannell. This has very large white flowers, produced on stout stems considerably above the dark foliage, characteristic of the "Lady." Lady Whitehead, though similar, is a cross less removed from the "Lady" type, and is more floriferous, has a greater number of trusses, flowers of rather less substance, and creates a beautiful display. The whole collection showed excellent cultivation.

Two dozen beautiful blooms of the Rose Catherine Mermet were shown by Mr. GEO. MOUNT, from his Rose Nurseries at Canterbury.

Mr. THOS. S. WARE, Hale Farm Nurseries, Tottenham, showed hardy flowering plants, such as Daffodils, Iris reticulata in several varieties, Saxifragas, Primula denticula, and others, Anemone pulsatilla, and the curious little Sceloporus Bigelowi, figured in *Gardeners' Chronicle*, March 3, 1894, p. 267. Fritillaria plurifolia, a plant also recently figured in these pages, was shown.

From Messrs. PAUL & SONS, The Old Nurseries, Cheshunt, came a collection of Christmas and Lenten Roses, also Cyclamen Coum zonale, several of the minute growing Saxifragas, and sprays of Alnus glutinosa aurea, with male flowers; and of Amygdalus Davidiana alba, &c., which appears to be very beautiful this season.

Messrs. BARR & SONS, King Street, Covent Garden, made their first exhibit of the season by staging some varieties of Holbores, also beautiful plants in pots of the pretty Lachenalias in variety, Crocuses, Scillas, Muscari, and other interesting "forerunners" of spring.

Mr. JOHN RUSSELL, nurseryman, Richmond, Surrey, exhibited a group of varieties of Euonymus of various sizes and degrees of variegation. Some of them were trained as standards. Also some large plants of Daphne Mezereum, and varieties called D. M. atro-rubrum and alba, Andromeda Catesbaei, with deep purple foliage, were remarked.

Messrs. WM. PAUL & SONS, Waltham Cross Nurseries, Herts, contributed a group of Camellia plants in pots; these were well-cultivated specimens, and represented choice varieties; many blooms were exhibited in boxes also. But for Messrs. Paul's commendable practice of exhibiting Camellias each season, the plant would be almost absent from the shows of the Society.

Sir TREVOR LAWRENCE, Bart., Burford, Dorking (gr., Mr. Bain), exhibited a plant in flower of a white Heuchera—H. sanguinea alba; also many spathes of a hybrid Anthurium, named Dr. Lawrence. The large spathes of this hybrid are flesh-pink in colour, and the spadix, which is almost at right angles with the spathe, is pale yellow, that becomes whitish towards the tip (First-class Certificate).

S. G. LUTWYCHE, Esq., Eden Park, Beckenham (gr., Mr.

S. Paterson), exhibited a plant of Iris chinensis, pale lilac or heliotrope-coloured.

Messrs. R. WALLACE & Co., Colchester, showed plants of Iris histrio, I. histrioides, I. reticulata, &c.

A capital exhibit of Ferns was made by Messrs. J. HILL & SONS, Lower Edmonton. Many of the choicer species and varieties of the better known genera were shown as finely-cultivated plants. Adiantums, Davallias, Nephrolepis, Pteris, and Gymnogrammas, were most numerous.

A miscellaneous group of forced flowering-plants, arranged with fine-foliated species, was shown by Messrs. J. PEED & SONS, Upper Norwood.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. J. O'Brien (Hon. Sec.), H. Little, H. M. Pollett, de B. Crawshaw, H. Ballantine, H. J. Chapman, W. H. Young, F. J. Thorne, W. H. White, E. Ashworth, J. Jaques, E. Hill, T. W. Bond, W. Thompson, C. Winn, S. Courtauld.

The show of Orchids was a good one, and those staged by Sir TREVOR LAWRENCE, Bart. (gr., Mr. W. H. White), were specially interesting, as demonstrating the fine proportions to which Orchids may be grown when afforded good cultivation over a series of years. Among the principal objects were a grand specimen of Sophronitis grandiflora, which came into the Burford collection in 1889, and it is now bearing forty-four flowers; Angreum pertusum, with twenty-five spikes, in 1878; Masdevallia polysticta purpurea, with many spikes, in 1878; Dendrobium x endocharis, in 1879; Angreum eburneum, Odontoglossum Andersonianum, and some plants of O. crispum, each of which had been many years at Burford, and had acquired great strength; Brasso-Cattleya x Lindleyana, with twenty-four flowers; Odontoglossum aspersum, bought in 1881; and a fine example of the pretty Epidendrum Endresii. Of the hybrids raised at Burford, there were shown Dendrobium x Juno, D. x Burfordiense, Cypripedium x hirsuto-Sallieri, Calanthe x gigas, &c.

Messrs. JAS. VEITCH & SONS, Ltd., Royal Exotic Nursery, King's Road, Chelsea, staged a fine group in which were three of their new hybrid Phalaenopsis, viz., P. x Cassandra (Stuartiana ♀, rosea ♂) which made its first appearance, had neatly-formed flowers of a bluish-white colour, and slight rose base to the sepals and petals; the long and peculiarly-shaped lip was rose-colour, with close brown spotting on a yellow ground at the base; P. x Vesta (Aphrodite ♀ x rosea leucaspis) had bright rose-pink flowers with some effective darker marking on the lip; and P. x Hebe (Sanderiana ♀ rosea) resembled a large P. intermedia Portei. In the middle of the group was placed a fine batch of Dendrobiums principally hybrids, and embracing the pretty D. x Dulce, D. x euosmum, and D. x e. leucopterum; D. x Dominianum, D. x endocharis, D. x Wardiano-japonicum, D. x Cybele nobilium, D. x splendidissimum, and D. x s. grandiflorum, D. x Schneiderianum, the pretty orange-scarlet hued D. subclausum, D. secundum, and D. s. album, D. aureum, D. crassinode album, &c. Other showy things in the group were Lælio-Cattleya x Myra (Trianei ♀ L. flava ♂), the reverse of that originally shown, bearing clear yellow flowers, with rose-pink veining on the front of the lip; Cypripedium x Enid (bellatulum x Spicerianum), C. x Lathamianum superbum, with very large and handsome flowers; Calanthe x Ariadne, with creamy-white flowers, bearing some purple blotches; Epidendrum O'Brienianum superbum, with dark scarlet flowers; E. x elegantium, E. x Endresio-Wallisii, Cattleya x Miranda, and other showy hybrids.

NORMAN C. COOKSON, Esq., Oakwood, Wylam, near Newcastle (gr., Mr. W. Murray), showed Calanthe x splendens (rosea x Bryan), with brilliant carmine-crimson flowers, darker towards the centre, but not exhibiting an "eye," as usually seen in hybrids of its class (Award of Merit); Phalaenopsis x grandis (Phaius grandifolius x Calanthe Bryan), the best of its class, bearing a stout, erect inflorescence of many showy flowers, in which the sepals were white, tinged with rose at the base, the broad, open lip white on the outside, and rich purple on the surface, with a few white stripes (Award of Merit). Mr. Cookson also showed the fine yellow Lælio-Cattleya x Doris (L. harpophylla ♀, C. Trianei); Cypripedium x Sanderio-superbum, C. x Youngianum superbum, C. x Morganiae, and a fine specimen of C. x Ceres (Spicerianum x hirsutissimum).

Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, (gr., Mr. W. H. Young), showed the true Lælia pumila prestans; and Odontoglossum Schillerianum, a rare and pretty variety with yellow flowers spotted with red.

P. CROWLEY, Esq., Waddon House, Croydon (gr., Mr. Harris), had the honour of receiving the only First-class Certificate awarded at the meeting for Lælia anceps Crowleyana, a very handsome pure white variety with broad open lip on the side lobes, on which were a few pale purple lines. The flower in form somewhat resembled L. a. Schroderiana.

Messrs. HUGH LOW & Co., Clapton, staged an effective group, including varieties of Cattleya Trianei, of which the handsome C. T. plumosa with a distinct purple feather on the petals was the best; Dendrobium nobile Ballianum, D. x splendidissimum grandiflorum, D. x Luna, D. crassinode, and other Dendrobiums; the showy Cypripedium x Prewetti, C. x Swinburnei splendens, varieties of Odontoglossum crispum, O. Hallii, O. tripudians, O. Rossii, &c.

Messrs. B. S. WILLIAMS & Son, Victoria and Paradise Nurseries, Upper Holloway, staged a group consisting of Cologynne cristata, Chatworth var.; Cypripedium x Williamsianum, C. x Pitcherianum, Williams' var.; C. x Ashburntoniae superbum, C. x calophyllum, C. x Spicerianum purpureum, C. Sallieri aureum, C. x politum, varieties of C. x

Leeanum, C. x cœnanthum superbum, C. x nitens, Lycaste fulvescens, with many flowers; Lælia anceps Williamsiana, varieties of Odontoglossum crispum, Dendrobiums, &c.

W. THOMPSON, Esq., Walton Grange, Stone, Staffordshire (gr., Mr. W. Stevens), showed Odontoglossum excellens spectabile, a very fine variety, which secured an Award of Merit on April 7, 1896; and O. hystris grandis, a beautiful variety of O. luteo-purpureum.

Mrs. WINGFIELD, Amptill House, Amptill (gr., Mr. Empson), showed a plant of Dendrobium, Wingfield's variety of nobile, with large and well-formed flowers. De B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr., Mr. S. Cooke), sent the Rosefield variety of Odontoglossum Rossii rubescens, a fine flower, the white parts of which are tinged with purplish-rose. F. W. MOORE, Esq., Royal Botanic Gardens, Glasnevin, Dublin, sent a flower of Maxillaria Augustæ Victoria, somewhat similar to those of M. Sanderiana, but with clear white sepals and petals, and a broad yellow lip having purple markings.

Mr. THOS. DUCK, Abbey Wood, showed a Cypripedium that is alleged to have been imported with C. insigne montanum, but which bears a marked resemblance to a small, pale form of C. x Leeanum. Major JOICEY, Sunningdale Park (gr., Mr. F. J. Thorne), showed a finely-flowered example of a large and pretty Lycaste Skinneri. Messrs. F. SANDER & Co., St. Albans, showed the pure white Calanthe rubens alba; a grand form of Cattleya Trianae of the C. T. Backhouseiana class, Lycaste Skinneri alba, &c. PERCY B. TUBBS, Esq., showed a very finely coloured Cattleya Trianae. Mr. C. W. CHARD, Clapton, showed Cypripedium Chapmani; and a fine group of C. insigne was staged by LORD FOLEY (gr. Mr. J. Miller), Ruxley Lodge, Esher.

Mr. Wm. Murray, gardener to NORMAN C. COOKSON, Esq., Oakwood, Wylam, showed specimens of his patent Orchid-stand, an excellent invention for raising plants above the staging, and obviating the destructive fungoid growths which nearly always occur where inverted pots or no elevators are used.

Fruit Committee.

Present: Philip Crowley, Esq., in the chair; and Messrs. T. Francis Rivers, G. W. Cummins, M. Gleeson, Jos. Cheal, Jas. H. Veitch, W. Poupart, A. F. Barron, J. Wright, Alex. Dean, Jno. A. Laing, J. W. Bates, C. Herrin, Geo. Woodward, W. J. Empson, F. Q. Lane, Jas. Smith, G. Reynolds, W. H. Divers, G. Norman, J. Willard, and Robt. Fyfe.

Mr. GEO. MOUNT, the indefatigable exhibitor of early Roses, contributed a collection of Apples, representing Cox's Orange Pippin, Dumelow's Seedling, Mère de Ménage, Court Pendu Plat, Newton Wonder, Bismarck, and others, in a capital state of preservation.

Out of many dishes staged, the best Pear in the flavour competition was Passe Crassane, shown by Mr. Geo. Woodward, gr. to ROGER LEIGH, Esq., Barham Court, Maidstone. These fruits were first-rate in quality, and the variety was further honoured by the award of a First-class Certificate. The fruits were from trees on the Quince, growing against a west wall, in light rich soil. The 2nd place was won by the variety Olivier de Serres, shown by Mr. W. H. Divers, gr. to the Duke of Rutland, Belvoir Castle, near Grantham. Mr. Divers had also the best Apple, in Cox's Orange Pippin, from an orchard standard on Crab stock, in strong clay; Mr. G. Woodward's Calville Blanche was 2nd.

A First-class Certificate was granted to Apple Lord Hindlip, shown by Mr. JNO. WATKINS, Pomona Farm, Hereford. This proves to be an excellent dessert or culinary fruit, and a late keeper. It has previously been granted an Award of Merit and was figured in these pages Jan. 25, 1896, p. 115.

Messrs. SUTTON & SONS, Reading, showed two flats containing twenty-four magnificent heads of Sutton's Superb Early White Broccoli, the heads being 8 inches in diameter, and beautifully firm, and of a creamy-white.

Mr. O. THOMAS, Royal Gardens, Frogmore, showed a nice-looking Cucumber, named Every Day, the fruit resembling Kenyon's Improved. It is a cross between Rochford's Market and Dickson's All-the-Year-Round (Award of Merit).

A Cultural Commendation was awarded to S. W. KEENE, Esq., Barnes, for some first-class Mushrooms.

Medals Awarded by Joint Committee.

Silver-gilt Flora to W. Paul & Son for a Group of Camellias.

Silver-gilt Flora to J. Veitch & Sons, for Orchids and Primulas.

Silver-gilt Banksian to J. Hill & Son, for Ferns.

Silver-gilt Banksian to Sir Trevor Lawrence, for Orchids.

Silver Flora to Messrs. H. Cannell & Sons, for Primulas.

Silver Banksian to Hon. H. C. Legge, for Freesias.

Silver Banksian to Mr. G. Mount, for Roses and Apples.

Silver Banksian to Lord Foley, for Cypripediums and Fruit.

Bronze Banksian to Messrs. J. Peed & Son, for Plants.

Bronze Banksian to Messrs. Low & Co., for Orchids.

HIGHGATE AND DISTRICT CHRYS-ANTHEMUM.

FEBRUARY 2.—At the Annual General Meeting of this Society, held on the above date, the financial statement showed that the income during the past year amounted to £165 6s. 6d., of which £63 7s. 6d. was subscribed, and the expenditure to £161 2s. 2d., of which £87 2s. had been awarded in prizes.

The last exhibition was considered very satisfactory, and it was decided that the show in November next should be held in the Holloway Hall, and extend over two days. Mr. C. F.

CORY-WRIGHT was elected President in succession to Mr. Birks, and Messrs. McKercher and W. E. Boyce were re-elected Treasurer and Secretary respectively.

BECKENHAM HORTICULTURAL.

FEBRUARY 4.—This Society has arranged an interesting course of lectures to supplement the ordinary weekly meetings, at which various papers are read, and discussions follow. The first lecture took place on Feb. 4, when Mr. James Martin, from Messrs. Sutton & Sons, of Reading, gave an interesting and instructive discourse on the Gloxinia.

The lecturer reviewed the history of the Gloxinia from its earliest known date, 1739, and described its evolution to the state of perfection to which this beautiful plant has been brought. Mr. Martin interspersed his remarks with many witty anecdotes.

The chair was taken by Mr. H. J. Jones, of Ryecroft, and a charming group of Cyclamen, brought by Mr. T. Croswell, created a deal of interest, and drew from both chairman and lecturer the highest compliment for cultural skill.

TREES AND SHRUBS.

PRUNUS DAVIDIANA ALBA.

THIS lovely shrub has been in flower in the Messrs. G. Cooling & Sons' Nurseries, Bath, since Jan. 20, and is so still. Prunus Davidiana rosea showed a few blooms on the 1st inst. Of this variety there are also some fine specimens in flower at Wayfield Batheaston. Both are still uncommon plants in our gardens. We also have in flower since February 1, Cornus mascula, the giant Saxifraga, the Wilson blue Primrose, Prunus Pissardi, P. sinensis flore-plena alba, P. fl.-pl. rosea, and others. F. Nash.

ENQUIRY.

"He that questioneth much shall learn much."—BACON.

WILL any correspondent kindly inform "J. M." of the present address of the raiser of *Rent payer* Pea?—a Mr. Brownhill as he believes.

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

THE PAST WEEK.

THE following summary record of the weather throughout the British Islands for the week ending February 5, is furnished from the Meteorological Office:—

"The weather during this period underwent a considerable change; at first it was extremely mild, with rain in the more northern and north-western districts, but with generally dry weather in the south and south-east. Later in the week, however, rough, cold weather set in, and squalls of wind and cold rain, hail, or sleet extended from the north to all parts of the Kingdom.

The temperature was very high during the earlier part of the period, but subsequently fell very quickly. The averages for the whole week were, however, again above the mean, the excess ranging from 2° in 'Scotland, N.' to 5° over the greater part of England. The absolute maxima were recorded between Jan. 30 and Feb. 1, and were very high for the time of year. In 'England, E.' (at Gellleston on Tuesday), and in 'Ireland, S.' (at Dublin on Sunday), the thermometer rose to 61°, and in 'England, N.E.' (at Shields and Durham) to 60°. Elsewhere the maxima ranged from 59° in the 'Midland Counties' and 'England, N.W.' to 54° in 'Scotland, N.' and the 'Channel Islands.' Towards the end of the week the daily maxima were low, in many instances less than 40°. The lowest of the minima were registered, as a rule, on the 5th, and ranged from 23° in 'England, S.W.', 24° in 'Scotland, N.', and 25° in 'Scotland, E.' to 29° in 'England, N.E., N.W., and S.' and 'Ireland, N.' and to 39° in the 'Channel Islands.

"The rainfall was much more than the mean in 'Scotland, N.', 'England, N.W.', and 'Ireland, N.', and slightly in excess in 'England, E.' and 'Scotland W.' In 'England, N.E.' the mean was just equalled, but in all other districts the fall was again less than the normal.

"The bright sunshine exceeded the mean over Scotland and in nearly all the English districts, but over Ireland and in 'England, S.W.' there was a deficiency. The percentage of the possible duration ranged from 34 in 'England, E.' and 30 in 'England, N.E.' and 'Scotland, E.' to 17 in 'Scotland, W.', 16 in 'Scotland, N.', 11 in 'Ireland, S.', and 9 in 'Ireland, N.'"

* This is the highest reading of which there is any record in Dublin in January. The record dates from 1871.

MARKETS.

COVENT GARDEN, FEBRUARY 10.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. ED.]

THE

Gardeners' Chronicle.

SATURDAY, FEBRUARY 19, 1898.

THE TABLE-GRAPE INDUSTRY IN FRANCE.

IT is estimated that there are 19 million acres of land in the world under vineyards—of this total, France claims nearly one-third; she had more before the phylloxera appeared, but replanting is rapidly making good the loss, as the cultivation of the Grape, whether for table consumption or wine-making, is very remunerative, as evidenced by the well-being and contentment of the growers. Besides, the culture of Grapes affords constant and agreeable employment nearly throughout the year. The culture of the Vine, M. A. de Candolle asserts, can be traced to the Bronze Age, as seeds have been found in the lake dwellings of Castione, in Italy, and leaves of the Vine have been discovered in the soft stone subsoil at Montpellier, which coincides with the pre-historic period of our globe. What about the origin of the juice—of wine itself? Pictet attributes it to the Semites and Aryans, and as these peoples migrated, they made known the process in the countries where they settled down, notably in Egypt, India, and Europe. Thus the Vine and wine possess very ancient title-deeds.

In general, table Grapes in France are grown in the open air, and by ingenious processes of conservation can be kept fresh up to June. Of course, there are hothouse Grapes grown, and of late the artificial culture under glass is spreading in Northern France, as at Roubaix, Lille, &c., where coal is relatively cheap, to dispute the foreign markets with Belgian forced productions. These vinery Grapes can never have any important sale in France; their price, 2s. to 3s. per lb., being only for persons with fat purses, and the owners of the latter being mostly *gourmets*, prefer the superior delicacy, flavour, and "bouquet" of the natural well-preserved Chasselas Grapes. From the closing days of June till the middle of July, France has no open-air grown Grapes; but then she has an ample supply of small fruits. Algeria sends the first consignments of fresh Grapes to the Paris central markets; they have not the fineness and delicacy of the Grapes of continental France, but they are rapidly becoming ameliorated by greater care in cultivation. Next to arrive are the Grapes from Vaucluse, the Eastern Pyrenees, Hérault, &c., and, in due course, the pleasant-eating Chasselas of Montauban and Toulouse. The Chasselas Grapes have a thin skin, crisp pulp, sugary melting like a bonbon, and of delicious flavour. It is not a wine Grape, because it does not yield much juice, and does not possess good keeping qualities; but it is a sure-cropping, profitable, table Grape, that thrives on strong lands, and in a humid climate. The several varieties of Chasselas are not distinctly marked, and their differences are due more to soil and culture than

to other causes. The Chasselas of Fontainebleau may be regarded as the parent of that celebrated variety, now so widely spread, because plants are raised in nurseries for sale.

Originally it came from the village of Chasselas, near Maçon, and was planted in the royal park of Fontainebleau during the reign of Henri IV. or Louis XIII. It was shoots of this royal Vine that Marmieux, in 1730, planted, and made famous, at Thomery, a picturesque village, 3 miles from Fontainebleau, and sheltered on the north and west by the wood-clad hills.

In autumn, no more beautiful walk exists than to descend from the forest-heights of Fontainebleau into the lowlands, for miles around the country only series of walls covered with Vines, espaliers, and *contre-espaliers*, are to be seen. This is the head-centre of the culture of the Thomery table-Grapes, that only became a world-celebrated industry since 1840. Although a few cultivators raise Grapes under glass, the normal culture is carried on in the open air. Perhaps the secret of the monopoly resides in the conservation of the fruit—as fresh and velvety as when first gathered on the Vine—till May or June, when they sell at from 5s. to 6s. per pound. The walls in the gardens are 33 feet apart, and 11 feet high; supports are fixed to allow of a sloping shelter of straw, wood, tarpaulin, or better still glass, to protect the Vine-espaliers from injury by frost and rain. In the spaces between the walls are the *contre-espaliers* with galvanised-wire for the branches, the latter equally protected from the severity of the weather by hoods of straw matting. All the Vine branches are, as a rule, trained mostly horizontally and vertically. Following the mode of pruning adopted, the Vines are planted 16 to 30 inches apart, and only one bunch of Grapes per bearing branch is desired. The Thomery Grapes owe their famous reputation to the *cisellement*, or thinning and *effeuillage*, or removal of foliage practised. When the Grapes are about the size of a Pea, the bunches are examined, and every berry tending to obstruct the development of its neighbour, or presenting the appearance of an abortion, is carefully removed by a sharp and fine-pointed pair of scissors—that operation is called *cisellement*.

The removal of the leaves, when they interfere with the development of the bunch, is *effeuillage*; the second removal of the leaf will not take place till the fruit be matured, and is intended to expose the berries to the sun, in order to acquire the golden hue so much desired by *connoisseurs*.

In consequence of the extension of hothouse raising of Grapes in the North of France, the large "Frankenthal" violet-black Grape is not so much cultivated at Thomery. Experiments continue to be successfully made with hybridisation, and some other practices, to obtain a golden Chasselas with berries as large as the Frankenthal. The secondary quality of Grapes grown at Thomery, those raised on the *contre-espaliers*, the insufficiently, or too-ripe, or the meagre-looking bunches, are packed in special small baskets, and sent to the Paris central markets, where they nevertheless obtain a top price. But the best Grapes, that is to say, all the prime crop, and those destined to be conserved till the spring, are cut with a pair of scissors or a pruning-knife, and the bunches handled with care, so as to retain their bloom. These bunches are left uncut as long as sunny days will permit, thus allowing much of the water in the berries to evaporate, and in that way augment

the quantity of sugar retained in the berries, of which as much as 30 per cent. has been found.

The Romans, in order to preserve Grapes from one year to another, inserted a part of the branch with the bunch attached in a glass-globe, and covered the mouth with pitch. At Thomery, growers have special halls or rooms maintained at a temperature of 39° to 42° Fahr., where, on racks, wide-mouthed bottles filled with water are ranged, slanting-wise, and into which the piece of the branch, nearly 3 inches long, that has the bunch attached, is inserted, and to be kept constantly wet. This will ensure the duration of the plumpness and the original freshness of the berries. In the bottom of the bottles should be placed a few pieces of charcoal to prevent the decomposition of the water. The Grapes to be thus preserved should always be cut during dry weather, with 3 inches of the branch attached to the bunch; the storeage-room ought to have its openings facing the north, and to be maintained hermetically closed, so as to guard against atmospheric variations. It is essential to inspect the fruit frequently, and remove all that is affected with must; place in a corner some lumps of quick-limestone or chloride of calcium to absorb humidity, when the hygrometer exceeds 72 degrees, and if a musty smell exists, burn a few sulphured wicks. Grapes that are not expected to preserve their pristine greenness are stored by the small growers at Thomery in the central room, on the first story of their dwelling house; the bunches are placed on open-work shelves, so as not to touch, and are covered over with very dry Rye-straw or Fern. The room must have facilities for ventilation, and the usual uniform temperature and hygrometric condition of the atmosphere secured. It has been found that Grapes obtained from Vines not less than ten years old, keep better than such as are produced by younger Vines, and that the products of argilocalcareous soils preserve better than those from silicious soils.

In Southern Russia, fresh Grapes are preserved in a well-closed cask with the finest cork dust, so that each berry be well embedded in the powder. In the South of France, where the Grapes are excellent and abundant, all attempts made to preserve them throughout winter have failed—at Montpellier especially, owing to the sudden transitions of temperature.

The packing of the Grapes for exportation is executed by women specially trained to the work; small deal boxes are lined inside with the whitest of paper, the border of the latter being of a lace pattern. The bunches of Grapes are then laid, stalk upwards, so as not to touch each other, with paper separations of an undulatory nature; a sheet of paper covers all, and the lid is closed down.

Hérault is the department which excels for ordinary vineyard table Grapes, and these are forwarded to Paris, from August to October, in circular wicker baskets containing 25 lb. of fruit. It boasts to have Chasselas as good as those of Thomery; which is not quite exact. An acre produces two tons of Grapes, which sell on the spot at a fraction less than one penny per lb., the transport to Paris, duties, storage, commission, &c., amount to 2d. per lb., so the retailer pays 3d. wholesale price, and sells at 5d. to 7d. per lb. The railway charge covers the return of the "empties." The "Grape-trains" leave Montpellier at midnight, arriving at Paris in 23 hours; the Grapes are delivered to the commission agent, and auctioned off six hours later. *Edward Connor.*

NEW OR NOTEWORTHY PLANTS.

CORIARIA TERMINALIS, Hemsl.*

IN the sixth number of the *Mittheilungen der Deutschen dendrologischen Gesellschaft*, just issued, there is a coloured figure of a plant named *Coriaria nepalensis*, but which is undoubtedly my *C. terminalis*, published in the work cited below, in 1892. It is so very distinct from *C. nepalensis*, that when one has fairly good specimens under observation there can be no question, yet herbarium specimens of *C. terminalis* have long been included under *C. nepalensis*. It was from excellent specimens collected by Mr. Pratt in West Szechuen, China, on the Tibetan frontier, at 9,000 to 13,500 feet, that I first discovered that it was an undescribed species. Further research led to the discovery of Indian specimens of the same plant in the Kew Herbarium, collected in Sikkim by Sir Joseph Hooker, nearly fifty years ago, at elevations of 9,000 to 11,500 feet. These specimens are marked "var. *sikkimensis*," though they are not distinguished from *nepalensis* in the *Flora of British India*.

The plant figured in the *Mittheilungen* was from the garden of Baron von St. Paul, at Fischbach, in the Riesengebirge; but its origin is not given. In his communication respecting it, Baron von St. Paul says he "could hardly expect that this charming shrub would prove hardy in his locality, though Mr. Max Leichtlin found it perfectly so in Baden-Baden."

It is described as always having terminal racemes of flowers, and in this character it differs from all other known species. From *C. nepalensis* it also differs in the leaves, being from 5 to 9- (usually 7-) nerved, as well as being a much less woody plant. Indeed, judging from the herbarium specimens, I came to the conclusion that the stems were of annual duration, and flowered only once; in other words, that it was a herbaceous perennial. Though Baron von St. Paul designates it a "strauch," it might from the figure in the *Mittheilungen* be either a dwarf shrub or a herb, not a shrub 8 to 16 feet high, as true *C. nepalensis* is. It certainly has the appearance of being a very ornamental plant, in the form of a dense bush, with crowded dark-green leaves, and terminal pendulous racemes of dark-yellow and chocolate flowers. My description in the place cited may be useful:—"Herba perennis (ut videtur), caulibus erectis, 2-3-pedalibus pauciramosis crassiusculis. Folia opposita vel subopposita, sessilia vel brevissima, petiolata, fere membranacea, late ovata vel interdum fere orbicularia, vel in ramulis lateralibus oblongo-lanceolata, 1-3 poll. longa, abrupte breviterque acuminata, basi cordata et semi-amplexicaulia vel rotundata, 5-9-nervia sed sæpiissime 7-nervia, subtus præcipue secus nervos asperula. Flores polygami, in racemos solitarios terminales, 3-7 poll. longos dispositi, pedicellis gracilibus puberulis vel asperulis, circiter semipollicaribus demum patentibus. Sepala ovata vel lanceolata, obtusa vel acuta. Petala per anthesin parva, quam sepala multo minora, post anthesin accrescentia, incrassata, intus carinata. Carpella glabra, carinata, sæpiissime bicostata."

There is one objection to planting this and other species of the genus: the attractive fruit is decidedly poisonous. The fruit, I may add, consists largely of the petals, which become fleshy, and enclose the dry carpels. Besides *C. nepalensis*, which extends eastward to Japan (*C. japonica*) and the Philippine Islands, there is one native of the south of Europe, and three of New Zealand, two of which have annual stems, and the third, a tall climber, is also a native of the Andes, from Chili to Mexico. It is figured in the *Botanical Magazine*, pl. 2470. *W. Botting Hemsley*.

DIDIERA MIRABILIS (FIG. 42).

Several years ago, the late Professor Baillon described in the *Bulletin of the Linnean Society of Paris* (1880, p. 258), a remarkable plant from Madagascar, and which was so anomalous that he thought it might eventually form the type of a new genus. The stems are something like those of the

succulent Euphorbias, and have long spines and leaves, and pendulous flowers in tufts. The perianth consists of three pairs of alternate rose-coloured leaflets. There are, according to the figure, eight hypogynous stamens, a superior ovary with one perfect, and, as it appears, two imperfect compartments. The solitary ovule is ascending anatropal. The ovary terminates in a long style, expanding at the top into a broad wavy three-lobed stigma.

In the atlas to the *Histoire Naturelle et Politique de Madagascar*, published by M. Grandidier, are figured without description, two species, *D. madagascariensis*, with a thick fleshy conoidal stem with spines and

house, and one out of doors protected by a bell-glass; the first, says M. Guihéneuf, did the worst. In autumn, after the fall of the leaf, they went to rest and were wintered in an intermediate house, and the soil kept just moist. In spring they were repotted and started into growth again. Now they are doing perfectly well, and have attained a height of about 8 inches. The soil used is sandy peat. In a young state, when at rest, they have much the appearance of a small Melocactus, but lose that habit as they get older.

The second portion of the seed was sown on pure sand kept perfectly dry in the same stove as the

FIG. 42.—DIDIERA MIRABILIS: SEEDLING PLANT ABOUT 8 INCHES HIGH.

tufts of linear-oblong leaves on the one side, and tufts of pendulous flowers on the other. The second species, *D. mirabilis*, is a weird uncanny-looking thing with spreading serpentine branches, thickly covered with spines. Through the kindness of M. Guihéneuf, 20, Rue Albany, Paris, we are enabled to give a representation (fig. 42) of one of the six seedling plants in Paris. M. Guihéneuf tells us that the plant grows to a height of several mètres on dry rocky soil. Three years ago a branch was sent to Paris in a wooden box. The flowers opened during the journey, and some of the seeds arrived at maturity. These were sown immediately in pure moist sand, and germinated in forty-eight hours, and the seedlings when strong enough were potted in thumb-pots; some were placed in a stove, some in a temperate

others. None of these germinated, but after six months the seeds were moistened and once more germinated in twenty-four hours. The plant requires a very sandy soil, moderate heat, plenty of air, moderate waterings, and a perfect rest in winter. Everything about the plant, its conformation, structure, and rapid germination in the presence of moisture, denotes the nature of its habitat, and suggests the treatment to be adopted here.

It is one of the most singular plants introduced of late years, and the botanists at present do not know where to place the new-comer. It is more like some of the odd-looking [plants of which the fossil remains only are known to us, and when we get it in cultivation not only its flower and seed but its anatomical conformation will require close scrutiny.

* Hooker's *Icnes Plantarum*, xxiii, t. 2220.

FIG. 44.—ASPHODELINE BALANSE GROWING IN THE CILICIAN TAURUS: FLOWERS WHITE. (SEE P. III.)

THE GENUS ASPHODELINE.

THIS week we publish a series of illustrations from photographs sent by Mr. Siehe, of Mersina (Asia Minor). The species have been identified by Dr. Udo Dammer, of the Berlin Botanic Garden. One view (fig. 44) shows a group of these plants as growing in their native country, Cilicia and Cappadocia. As the

those of *A. Balansæ*, inflorescence irregular, fruit much constricted in the middle (fig. 45). The last two species attain a height of 5 feet, and the inflorescence is sometimes ramose.

4. *A. Dammeriana*, Siehe, sp. nov. Stem smooth, without scales; height, 2 to 3 feet; inflorescence almost always branched, flowers white, fruit spherical.

5. *A. imperialis*, Siehe, sp. nov. A fine plant,

FIG. 43 — ASPHODELINE BALANSÆ

plants are quite hardy it will be seen that they are likely to form very fine decorative plants. "The species specially alluded to are:—

1. *A. brevicaulis*, yellow-flowered species.

2. *A. Balansæ*, with a stem destitute of scales, white flowers, oblong fruit, somewhat constricted in the middle. This fine plant has the habit of a Dasy-lirion, the tuft of leaves at the base has a diameter of 3 feet (fig. 43).

3. *A. isthmocarpa* has flowers rather larger than

attaining a height of 7 feet; inflorescence apparently always unbranched; fruits spherical.

6. *A. taurica*, an alpine species, with leaves up to the base of the inflorescence; fruits oval. A very interesting species, from its snow-white bracts and white flowers; see *Gardeners' Chronicle*, March 13, 1897, fig. 52.

7. *A. Basilii*, Siehe, sp. nov. A species with ovate-oblong fruits, found near Cæsarea, on Mount St. Basil, whence the name, *U. D.*"

ALPINE GARDEN.

POLYGALA CHAMÆBUXUS.

ALTHOUGH not a rare plant, the Box-leaved Milk-wort is yet absent from many alpine gardens where it could be grown with advantage. Its evergreen habit, added to its pretty yellow and white flowers cannot fail to please those who see it for the first time, nor to give lasting satisfaction to its grower. Introduced about 240 years ago, from the Alps of Austria and Switzerland, it has but slowly acquired its present position of favour among alpine flowers, prized by those who know them well.

Polygala Chamæbuxus is a choice little plant which rarely grows more than a foot in height, and is more frequently seen much dwarfer. It is of shrubby, evergreen growth, and the branches are clothed with small, light green leaves, resembling those of the common Box. The flowers greatly resemble those of a papilionaceous flower, and, as has already been mentioned, are white and yellow in colour, the yellow changing to buff with age. There is also a very beautiful variety known as *P. Chamæbuxus atropurpurea* or *purpurea*. This has the calyx and wings of a fine purple colour. This variety is said by M. H. Correvon, in *Le Flore Colorié de Poche*, to occur in the granite districts, and more especially in the Southern Tyrol. In the *Botanic Garden*, where the type is figured, Maund tells us that several varieties "are spoken of, some with red or purple flowers, others with red and yellow." *P. Chamæbuxus* is not difficult to cultivate, and may be grown well in a peaty soil, or one composed of peat and loam. I have seen it occasionally doing well in a clayey soil. It is increased by division or by cuttings; and the means for the former are easily procured, as the plant increases naturally by sending out creeping roots. Cuttings may be taken off with a heel of the old wood. The plant comes into flower in April or May, and lasts in bloom for a long time. The writer prefers to take cuttings in spring, and to divide the plant either before it comes into flower, or in September. It may be grown in the border as well as in the rock-garden, and will give satisfaction in either.

IRIS CRISTATA.

The Irises are amongst the most admired of our border flowers, and yield us also a few rock-garden plants of much beauty. Among these none are more interesting or more beautiful than *I. cristata*, from the south-east of the United States, occurring on the mountains of Kentucky, Virginia, and Carolina. It appears to have been introduced about 1756, and Mr. J. G. Baker, in his *Handbook of Irideæ*, says, "there is a specimen at South Kensington, dried, from the garden of Collinson in 1766." It is *I. odorata* of Persoon, and *Neubeckia cristata* of Alefield; while *I. cristata* of Miquel is *I. tectorum*, a Chinese and Japanese species. *I. cristata* belongs to the sub-genus *Evansia*; it is an exquisite little plant, possessing flowers which are large in proportion to its height. The flowers are of a beautiful pale lilac with yellow throat, and a pretty yellow crest; they appear in April or May, but in the north generally in the latter month. Two flowers are usually produced on each stem. The leaves are a pretty light green, and not so long as to interfere with the effect of the flowers. The normal height of *I. cristata* is given as 6 inches, but it is frequently considerably taller if in a favourable situation.

There appears to be a current impression that this little fragile-looking Iris is not quite hardy, and it is undeniable that the plants are frequently lost the first year or so after being planted. I do not think this is due to any tenderness, but simply to the Iris not having had time to take root properly before unsuitable weather-conditions weaken or destroy it. It prefers to have its root-stock above the surface of the soil, with only its fibrous roots in the ground. In planting, this is frequently disregarded, and the rhizomatous root-stocks are covered, with the result that decay sets in. It is highly desirable that this Iris should be planted either in spring or in July or August. A light and fairly dry sandy peat soil is generally recommended for it, but it does not thrive

so well if not properly supplied with moisture in summer. Some continental growers, indeed, go so far as to recommend growing the crested Iris as a bog plant, with moss placed over the root-stocks. It does well planted on a flat terrace in the rock-garden, where it soon spreads and, when happy, forms a thick, dense tuft of leaves, and gemmed at the flowering time with many exquisite blooms. It is also used in some gardens with much success as a border plant or as an edging. In an Irish nursery there is a long, broad margin of Iris cristata growing in fairly heavy soil, and delighting everyone with its vigour and beauty. Did it do as well everywhere, no one could fail to welcome it in the garden.

ANDROSACE LANUGINOSA.

This Androsace is one of the best of our rock plants, and one which is becoming more appreciated as it is seen that its requirements are not very exacting upon its cultivator. It comes from the Himalayas, whence we have a considerable number of plants reputedly difficult to grow in our climate. The silkiness or woolliness of its foliage would point to the desirability of protecting *A. lanuginosa* from wintry rains, but, after some years' trial without such shelter, I have come to the conclusion that it is not absolutely essential, even if it is beneficial. For some years a covering with a sheet of glass was adopted, but as the plants increased in size, they became too large to be thus shielded, and they are now left uncovered. In consequence, at the dawn of spring, they look rather dejected and unhappy; but a week or two of seasonable weather will soon bring them round again.

Androsace lanuginosa is a choice alpine flower, with long trailing shoots covered with leaves of a beautiful silvered-silky appearance, caused by the silk-like hairs which cover them. It looks at its best when it depends from the face of a rock. In such a position its silvery leaves look pretty, and when in flower, the appearance of the whole is very pleasing. The beautiful delicate rose flowers with yellow eyes are produced in umbels. A good-sized plant will flower very freely, and the bloom will be continued from June till October. Occasionally in mild seasons stray flowers will appear later still.

An open and sunny situation is the one it prefers, and the soil in which it thrives best is one composed of sandy-peat. Although of trailing habit, it does not look flat on the surface, as it is rather inclined, if on the level, to form a little shapely mound, and those who do not find it convenient to give it a pendent position, will not regret growing it on a level terrace, provided that the latter is large enough to allow the *Androsace* to extend. Its height, if grown in this way, is from 6 to 9 inches. It was introduced about 1842, and a variety named *A. l. Leichtlini*, with paler flowers, and a deep crimson eye, has since been brought into cultivation. Either may be propagated by cuttings or layers. *S. Arnott, Carsethorn, by Dumfries, N.B.*

ORCHID NOTES AND GLEANINGS.

SPIRANTHES COLORATA VAR. MACULATA.

FROM Mr. Otto Froebel, of Zurich, comes a fine inflorescence and some foliage of this handsome South American terrestrial Orchid, of which he justly expresses great admiration in the letter which accompanied it. Its foliage is of a bright green hue, marbled and spotted with silvery-white; and from the centre of the plant rises the erect inflorescence about 1 foot in height, the upper half of which bears a head of pretty coral-red and white flowers, each furnished at the base with a coral-red bract. The green variety, known formerly as *Neottia* and *Stenorhynchus speciosus*, is an old friend in gardens; and the spotted-leaved one has often appeared, and an account of the difference in its foliage from the type had been variously named, until Mr. N. E. Brown identified it as above, and recorded it in the *Gardeners' Chronicle*, 1883, i., p. 210. It makes a useful decorative plant, lasting in beauty in a healthy room for upwards of six weeks.

DENDROBIUM NOBILE VARIETIES.

A fine set of grand varieties of *Dendrobium nobile*, some of them equal in size and breadth of petal, is forwarded by Messrs. James McBean & Sons, florists Cooksbridge, Sussex, who have made for themselves a good name as cultivators of Orchids useful for market purposes. One handsome kind has white flowers slightly tipped with purple on the sepals and petals. The lip has a maroon blotch at the base, primrose-coloured front, and purple tip. The opposite of it is coloured all over, except the white zone on the front of the lip, with a rich crimson purple hue; and between these two extremes are many handsome variations. Peculiarities in all the forms are the unusual length of the flower-stalks and the extraordinary size of the lips. *J. O'B.*

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Odontoglossum crispum.—Numerous importations of this species taking place at the present season, some hints as to treatment may be acceptable to those about to commence their cultivation. In removing them from the stems and branches of trees, the collectors will have damaged the roots very considerably, and the plants will have been further weakened by being deprived of moisture and light on the journey, and the vicissitudes to which they must necessarily be subjected; the leafless pseudo-bulbs, therefore, are wasted and shrivelled by the time they reach the gardener. To attempt to make these pseudo-bulbs at once plump, or to excite growth after losing a large portion of their vital force, would usually end in failure. The better method on receiving imported plants is to prepare a stage in the cool-house, and if it consists of quartering, overlay it with boards or slates, and a thin layer of sphagnum-moss spread over these. Then having cut away all decayed parts, and cleansed the plants from dirt and insects, lay the plants on the sphagnum apart from each other. At this season, owing to the moist air in the cool-house, there is no necessity to moisten them; for evaporation of the juices is at once arrested, and in due time the back pseudo-bulbs send up sap and enable the leading bulb to distend itself, and to push out a new growth, from which sooner or later roots will appear. When this stage is reached the plants should be potted; but instead of potting up the whole of them, select only those that have made the strongest start, and do not make up specimens by putting several pieces together, it being almost certain that the varieties will differ in their flowers, scarcely two being found exactly alike. Not unfrequently *O. Lindleyanum* and *O. gloriosum* are imported with *O. crispum*, which, if made up in the same pot, would have to be pulled to pieces later on, probably to the detriment of the plants. Each piece should be put into as small a pot as can conveniently be used, filling them almost to the rim with crocks, with but a thin layer of sphagnum-moss at the top, the base of the plant being kept just above the level of the rim, then a small quantity of peat and moss should be packed tightly around each plant, so as to keep it firmly in its place. Stand the plants in a damp corner of the house, and keep the atmosphere about them cool and moist; the object of doing this being to keep the plants fresh without having recourse to heavy applications of water during the first few weeks. As the roots push their way into the soil and among the crocks, the growths will increase in vigour, and water at the roots may be safely afforded, gradually at the first, but increasing in quantity as growth progresses. Exposure to strong sunshine will cause the loss of the young leaves, to avoid which careful shading is necessary. By the month of September, these imported pieces should have completed their first growth, and probably some of them will be starting to grow again, rendering repotting necessary. Imported *Odontoglossums* which start with vigour at the first sometimes flower the first season, and those who possess any of the plants will be desirous of seeing the flowers, but it is wiser to reduce the number to one or two on a spike. *O. crispum* is a plant very impatient of artificial heat at any season, and no more should be employed than is necessary to maintain the temperature at about 45°. From the present time it is probable that very little will be required, and in warm weather not any. Like most Orchids, they require ventilation whenever air can be admitted with safety, regulating the volume of it in accordance with

the outside temperature. Cold draughts should not be permitted to reach the plants, and on bright, cold days, when the outer air is below 40°, air should not be admitted with the object of keeping down the temperature, but blinds or shading should be used; but with an outside temperature of 45° and 50°, all the bottom ventilators may be opened wide, and when it is 50° out-of-doors air may be admitted gradually at the top as the warmth inside the house increases.

Miscellaneous Species.—The distinct looking *Odontoglossum Uro-Skinneri* may be repotted, in ordinary Orchid compost. Pot the plant as advised for *Masdevallia tovarensis*, and grow it in a moist, shady part of the *Odontoglossum*-house. *O. bictonense*, and its variety *album*, will thrive under the same kind of treatment. *Odontoglossum nebulosum*, and its unspotted variety *candidulum*, are both growing freely. It succeeds well under the same cultural conditions as *O. crispum*. The same remarks apply to *Masdevallia racemosa Crossii*, a plant now rarely seen in bloom, but which has been in flower for several weeks past at Burford.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Heliotropes.—If a quantity of plants is necessary for bedding, the seed should be sown now in a warm house. Prick out the young plants when large enough, and grow them in considerable warmth for a time, repotting them as often as may be necessary. They may be hardened-off gradually during May. The usual method of propagation is by cuttings, which should be dibbled in sand or cocoa-nut-fibre, and kept in a warm house or hot-bed until rooted. Care is necessary in watering them, as the young plants are liable to damp off if afforded too much water at the root or atmospheric moisture. Large plants when trained pyramidally are very suitable for use as centre plants in beds, or as isolated specimens plunged in the turf. In Devon and Cornwall planted against walls and buildings the *Heliotrope* flowers the greater part of the year.

Mathiola bicornis (the night-scented Stock) is an annual worthy of culture by reason of its scent alone. The plant grows about 1 foot in height, and has flowers very similar to those of the Virginian-stock, which upon the approach of evening fills the whole surrounding air with its aroma.

The Sub-tropical Garden.—The plants intended for this portion of the garden should be sown during the present month. Such plants constitute a happy relief from the characteristics of the usual summer-bedding. *Acacias*, possessing light and graceful foliage, have a fine effect when planted amongst the purple and crimson foliage of the *Amaranthus*; *Ricinus* (the Castor-oil plant), is of upright growth and magnificent foliage; *Daturas* (*Brugmansias*), with their large trumpet-shaped, deliciously fragrant flowers. Several of the species of *Eucalyptus*, but particularly *E. globulus*, are also useful for this style of gardening. Intermixed with these and similar plants should be planted Lilies that flower during summer and autumn, *Gladioli*, *Montbretias*, and *Hyacinthus candicans*. The beds should be composed of light sandy soil, and a liberal supply of well-rotted leaf-mould may be worked into them previous to planting. If a little peat can be added, the better will be the results.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Cucumbers.—Plants which have been in bearing throughout the winter will appear, as the days lengthen, to have taken a new lease of life, and will begin to grow anew with freedom. At this time the old, unproductive bine should be gradually removed, so as to give room for the new to extend. In order to assist the plants, they should be afforded a dressing, 1 inch in thickness, of light turfy loam three parts, and spent Mushroom-bed manure one part. Those plants that were set out in the beds early in January, if they have been subjected to the treatment advised, should be growing and gaining in strength, and their roots permeating the soil in every direction. When the roots show on the outside of the hill, place some rich mould 1 to 2 inches in thickness on the latter, and 3 or 4 inches around the sides. This additional soil should have been warmed previous to employing it. The bine of the plants should be induced by stopping and training to cover the lower part of the trellis first, in order to make the most of the space at command. Let the removal of the laterals from the main stem cease for a time, and at one joint beyond the point where the stem has

reached the trellis nip off the point, and then endeavour, by the suppression of weak growths, to throw the strength of the plant into three main shoots, which should when long enough be secured to the trellis, the side ones at a right angle to the central one, which will be allowed to extend onwards as the main shoot, and in course of time to develop other lateral shoots, and cover the entire space. Minor laterals may be stopped at the third leaf, reckoned from the point of issue. It is better to have some definite method of training the bine, than to let it wander at will over a trellis as some do. It is very necessary to avoid the crowding of the trellis with foliage at this season; and the removal of spent leaves and redundant shoots must be attended to frequently, and not left untouched for weeks, and then the plants denuded wholesale at one time. Do not exhaust the plants by excessive cropping, or leave mis-shapen fruits to develop. Those who grow their early plants in pits, and do not use a trellis, should employ cucumber-glasses or boxes if they want straight fruits, although this is a matter of no consequence when the fruits are sliced or stewed. I can give no rule for affording water to the beds, as so much depends on the nature of the soil—its depth, the sort of bottom-heat supplied, and the kind of house or pit. The best guide in this matter is to have several test-sticks thrust into the bed to the depth of a foot, and these should be examined twice a week. The soil must be kept in a moderately moist condition, not, however, soddened with water at all times, or souring will occur, followed by an unhealthy state of the plants. As a considerable amount of fire-heat is necessary, there is always the danger of having red-spider and thrips attacking the leaves; and to check the ravages of these pests of the Cucumber, a humid air must be maintained at all times, and a gentle syringing of the foliage practised once or twice daily, according to the state of the weather. Plants raised from seed sown early in January will now be large enough for planting in the beds, which may be done according to the directions given at the time of sowing.

Melons sown at the same time will be fit for planting out. Some gardeners construct their Melon-beds above a chamber heated by means of hot-water pipes, and others employ a bed of Oak, Beech, or Chestnut-leaves and stable-litter, or leaves alone 2½ to 3 feet deep, in addition to the hot-water heating. The fruit from a hot-bed of leaves, &c., is always of a better flavour than that from water-heated beds, probably because the soil requires fewer applications of water. If an ordinary hot-bed be used, place heavy loam in a moderately moist condition to a depth of 8 inches on the bed; and if it be a bed over a chamber, use a little more soil, treading or beating it firmly, and let a day or two elapse for the soil to become warmed before planting the Melons. The bed should have a warmth of 80° to 85°. On a bed 3 to 4 feet, and a trellis 6 to 8 feet wide, two rows of plants may be grown on slightly-raised mounds at 3 feet to 3 feet 6 inches apart. In planting, sink the balls till the soil reaches the two cotyledons, but letting these stand clear above the soil, and firmly press the latter round the balls. Secure each plant to a stick long enough to reach the trellis, and pinch off all growths up to within two joints of the trellis. Use the syringe and warm water once only on fine days, and not at all in cloudy moist weather. The plants succeed in a drier air than Cucumbers, and in a warmth of 65° to 70° at night, and 75° on dull days, and 85° on sunny ones. Keep the house rather close for the present, and shade from bright sun for a few days after planting.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

The Sowing of Onion-seed.—The chief sowing of Onion-seed should be made as early in the spring as the weather and the state of the land will allow; a dry day should be taken advantage of when the soil is dryish on the surface to give the plot a slight dressing of soot and salt, to stir it with a fork to a not greater depth than 6 inches, breaking the clods and making it level. This done make it firm by closely trampling it, and then make it smooth with a wooden rake. It will then be ready for drawing the drills, or rather for placing a row of slight pegs at either end of the plot at 12 inches apart to show where the drills will come, and to mark out the alleys. An Onion-bed may consist of five or six rows, and between the beds there should be alleys of 1½ to 2 feet wide for the convenience of thinning, cleaning, drawing the bulbs, &c. A drill should be drawn to the depth of 1 inch, and when the seed is sown thinly

therein, it should be closed with the feet from both sides at once, and then a short-toothed iron rake should be used to make the surface smooth. Onion-seed may be broad-casted over a bed of 5 feet in width, and covered to the depth of ½ an inch with the surface soil from the alleys. The Onion-bed should be made firm by beating it with the back of a spade, or by passing a wooden roller over it. Straw or pale brown skinned varieties are best for late keeping, and the following will be found excellent: James' Keeping, Bedfordshire Champion, Strasburg, Improved Reading, Brown Spanish, Giant Zittau. Blood Red is perhaps the best red-skinned late-keeping Onion. The white-skinned varieties are, White Spanish, White Globe, Rousham Park Hero, all of them good for use in the autumn and early winter months. The Queen is a small early variety, which if sown at this season on warm borders will afford usable bulbs by the end of June. It is a variety that every owner of a small garden should grow.

Rhubarb.—The present month is suitable for lifting and transplanting Rhubarb roots. As this disturbance of the plants checks growth for one season, only a portion of the stock should be lifted. Let the root-masses be carefully trenched out with all their roots, and if they are large, split them up into two or three pieces, each furnished with one or two buds; and plant them 3½ by 4 feet apart in richly-manured, trenched ground, burying the crowns 1 inch below the soil. No stalks should be pulled from the transplanted roots till the following year. The old plantation should be afforded a liberal dressing of bone-meal or cow-stall manure, digging the dressing in without injuring the roots of the plants.

Forcing Vegetables.—The supply of forced French Beans should be maintained by weekly sowings, and a hotbed for forcing Asparagus should be made, following previous instructions as to making it. Place roots of Seakale and Rhubarb in the Mushroom-house or other suitable place; or in the case of Seakale forced in the open, fresh beds may be covered with pots and stable litter and tree-leaves, getting these in a fermented state before putting them round the pots. Preserve the heat in forcing-beds by taking away the old, and placing fresh warm linings of prepared materials around them, and see that the lights are well protected at night with mats and litter; afford air to the inmates whenever the weather is favourable.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Bougardias.—If an increase of the stock of plants be desired, some of the old plants may have the soil shaken from the roots, and the strongest roots removed and divided into lengths, laid in a mixture of leaf-mould and sand in pans or boxes, affording a soaking of water and placing them in a close hot-bed or case. Plants that were placed in pits may now be lifted, have the shoots pruned hard back, and be then placed close together in boxes, filled with leaf-mould and sand, when, if stood on the hot-water pipes in a stove or other hot-house, and kept moderately moist and syringed, they will start into growth in a short space of time.

Eulalias.—Plants which have been rested may have the spent soil shaken from the roots, and be re-potted. If an increase be required, divide the roots, and place the divisions in pots of a size suitable for indoor decoration. A compost consisting of good loam two-thirds, spent Mushroom-bed manure one-third, and sharp sand suits them. In order to have some of the plants available in the autumn, keep them in a cool position, and the soil on the side of dryness for some time longer.

Acalyphas.—The tops of lanky plants may be made into cuttings, and inserted in thumb-pots in light sandy soil, and placed in a hot-bed frame to be rooted. Do not allow the plants to become pot-bound in the early stages, or they will soon lose their bottom leaves. The old stems, after being cut back should be kept rather dry at the root till they break anew, afterwards repotting them in a compost consisting of loam, leaf-mould, and sand, pressing the soil firmly about the roots. When in active growth, abundance of water, with occasional doses of manure-water, are required. Let the plants stand close to tiff glass, in order to ensure high colour in the foliage.

Cocos Weddelliana.—This Palm should be examined in case Thrips or red-spider infest the foliage, and if any are found, clear them off with a bit of sponge dipped in a solution of Gishurst soap. Plants requiring a shift into larger pots should be afforded a

mixture of good fibrous loam and peat, with some leaf-mould and sand added. Should the roots be in a bad state from over-watering and low temperature, shake the soil from the roots, cut off all decayed portions, and repot into a much smaller pot, affording water only when really needed, and giving them stove temperature. Where a supply of small plants is required for table-decoration, this species of *Cocos* is an extremely useful one, remaining of a usable size in presentable condition for a considerable length of time.

Geonoma gracilis is another useful Palm for decorative work, and a similar kind of treatment should be afforded as that recommended for the foregoing.

Araucaria excelsa.—In the cool conservatory, and for house decoration, this plant remains for a long time in a presentable condition. It requires a fair amount of root-room in the early stage of growth; when, however, the plant comes into a 6-inch pot, repotting is only needed when it has become top-heavy. It should be grown cool, as heat causes spindling of growth, and weakness of stem. When well established and rooted, plenty of water should be afforded, and an occasional dose of soot-water when the plant is in active growth does good.

THE HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Morello Cherries on north walls are often the last fruit-trees to be pruned and nailed, but the present mild season is exciting them into growth, and they will need attention much earlier than usual. As the fruit is borne chiefly on one-year-old growths, the most suitable method of training is the "fan-shape;" and an important item in the pruning is to remove as much as possible of the old wood yearly, so that young shoots may be laid-in at full length in its stead. These young shoots should now be relieved of the shreds, sticks or ties, by which they were secured in position during the summer, so that the walls may be thoroughly cleaned of cob-webs, decayed leaves, and other refuse that harbour injurious insects, and especially spiders, the webs of which cause much disfigurement of the fruits. So much of the wood on these trees is removed annually that the shoots may be trained-in rather more closely together than other fruit-trees; but young shoots should never be placed closer together than 2 inches. Those shoots that were cut back in the summer to 3 inches should now be further shortened to the base-buds, which will form short fruit-bearing spurs, and furnish young wood for laying-in next season. Keep all the branches as straight as possible when training, and it is fairly easily done as the wood is very pliable. For directions as to a winter dressing for Cherry-trees, see ante, p. 98.

Pears.—The pruning of pyramids and bushes should be completed at once, as the buds are fast pushing into flower. Trees that have been recently root-pruned will not make so much growth this year; if they have space, therefore, the leading branches need not be pruned so severely as heretofore. Take care to shorten any spurs that are getting long, or the fruits will be dashed about by the wind. If the trees are too full of wood, take away some of the main branches, to allow plenty of air to circulate among the leaves. Should a tree grow habitually strong, yet produce but few fruit-buds, it should be root-pruned; as see p. 23; but this must be done immediately, or deferred until the autumn. The leading shoots need only be shortened one-third of their length, if there is room for a further extension of the tree. In all cases cut to a bud pointing in the direction the young growth is required to take. Shoots that were shortened during summer to 3 inches should be cut back for half their length. Some varieties form flower-buds on the young growths only, and in pruning these, the shoots without flower-buds may be shortened; and the others, if sufficiently long and pliable, may be tied to the main branches, in order to avoid damaging the fruit by wind, and then be cut off after fruiting.

Apple Bushes.—The above remarks on Pear-trees apply also to Apples, with the exception that Apples should be given much more light than Pears sometimes obtain, in order to obtain fruits of full colour and flavour. Large pyramidal trees are not the best adapted for this, and the finest Apples are obtained from thin, vase-shaped bushes, which are kept quite open in the centre. Considerable care in training is necessary before the bushes can be got into this condition, especially the more upright-growing varieties; but after five or six years the branches become rigid, and the stakes that hitherto have been used can be entirely dispensed with.

APPOINTMENTS FOR THE ENSUING WEEK.

MEETINGS.

THURSDAY,	FEB. 17	Annual Meeting of Kew Guild at 8 P.M.
SATURDAY,	FEB. 26	Royal Botanic Society—General Meeting.

SALES.

MONDAY,	FEB. 21	Roses, Fruit and other Trees, Bulbs, &c., at Mr. Stevens' Rooms.
TUESDAY,	FEB. 22	Imported and Established Orchids, Carnations, Begonias, Montbretias, Azaleas, &c., at Protheroe & Morris' Rooms.
WEDNESDAY,	FEB. 23	Japanese Lilies, Continental Plants, Roses, Gladioli, Herbaceous Plants, &c., at Protheroe & Morris' Rooms.
		Roses, Fruit and other Trees, Bulbs, &c., at Mr. Stevens' Rooms.
THURSDAY,	FEB. 24	Roses, Carnations, Begonias, Hardy Plants, &c., at Protheroe & Morris' Rooms.
		Roses, Fruit and other Trees, Bulbs, &c., at Mr. Stevens' Rooms.
FRIDAY,	FEB. 24	Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—39° 8'.
ACTUAL TEMPERATURES:—

LONDON.—February 16 (6 P.M.): Max., 54°; Min., 45°.

PROVINCES.—February 16 (6 P.M.): Max., 51°, south-west Ireland; Min., 36°, Aberdeen.

San José Scale. THE American horticultural journals are filled with articles on the spread of this pest (figured in our last issue, figs. 37-40, p. 103), and with the enactments made by the several States in the Union, and Provinces of the Dominion, to prevent its introduction, or check its development. On the whole, we glean that while there is ample reason for care and watchfulness, there is none for panic, and that, like the Colorado beetle, it may not come at all.

At a recent meeting of the New Jersey Horticultural Society, Prof. J. B. SMITH, the State entomologist, is reported in the *National Nurseryman* to have said:—

"I am happy to be able to say that I believe that the insect can be controlled with comparatively little trouble, but will say at once that no such thing as extermination now is possible in this State, though it is possible to completely rid one or a hundred trees, or an entire orchard, which is quite a different thing from exterminating it. My chief reason for saying that the insect cannot now be exterminated is, that it has become established everywhere in the region between Burlington and Camden. We must deal with the scale as a native insect in the future. We must recognise the fact that it is one more enemy to be fought by the fruit-growers, but at the same time there is no reason why that enemy should not be conquered like others.

"We know that kerosene will kill San José scale at any time of the year wherever it touches them. It will not harm plant-life if not used in excessive quantity or under such circumstances as to prevent evaporation. Kerosene mixed with soap makes a mixture which will not readily allow the kerosene to evaporate. The kerosene must be put on in the finest possible spray, and no more used than is absolutely necessary to wet. To show what I mean, I say that with an atomizer holding one pint I covered completely a Pear-tree in full foliage, 10 feet in height, and with a diameter through the branches of fully 5 feet. The application cost but one cent. for foliage. Whale-oil soap is not so effective as kerosene in penetrating the crevices. There is one point not quite settled, and that is the effect of kerosene upon fruit-buds."

If it can really be controlled by spraying with kerosene emulsion, the danger to our orchards is less than in the case of "American-blight." At any rate, our horticultural

lecturers should make known the characteristics of the insect, and insist on the necessity for constant watchfulness.

For years we urged the establishment of peripatetic horticultural teachers, and of late we have had the pleasure of noting the good work accomplished by them now that they are appointed. The threatened spread of the San José scale is a case in point. Energetic as the conductors of the horticultural press may be, and wide as is their circulation, yet it is certain that a large proportion of the classes most concerned and most in need of information, either do not read, or do not heed what they read. How often do we find information, which has been given repeatedly in these columns, requested, not only by beginners and amateurs, but by business men on subjects directly concerning their industry! Not a week passes in the season but diseased Tomatos or Cucumbers, which have been described and figured scores of times, are sent us, not only by the amateur or private gardener, but by the commercial grower; who is obviously quite uninformed as to the nature of the disease, and the means, if any, of dealing with it. A competent instructor, with illustrative specimens and drawings, can reach some classes of the horticultural community more directly than the press can do, and hence it is that we suggest the San José scale as a subject for a lecture before fruit-growing communities. A great deal of good will be done by the inculcating of general principles, even if in this particular case there may be no need to apply them. There are only too many similar visitations where, as Captain CUTTLE says, "the bearings of this observation lays in the application on it."

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, February 21, 1898, when a paper will be read by Mr. T. W. WHEELER, Q.C. (Associate), entitled "Legal Liability for Professional Opinion." The chair will be taken at 8 o'clock.

LINNEAN SOCIETY.—Mr. W. C. WORSDELL, F.L.S., read a paper at the meeting of the Society on Thursday, February 3, on "The Comparative Anatomy of certain Genera of the Cycadaceæ." The chief points touched upon were:—In *Cycas*, the conduplicate vernation and arrangement of the bundles in the fleshy hypogæal cotyledons, the secondary extra-fascicular rings, the concentric cortical strands, and, in one species, the peculiar concentric structure of the leaf-traces, in the stem, and in the hypocotyl some curious concentric strands running obliquely out from the cylinder, and, in a small seedling, the secondary vascular cylinders lying outside the normal stele; in the seedling of *Stangeria paradoxa*, the small primary concentric bundles in the stalk common to the two cotyledons, which both higher up and lower down become collateral, and in the adult stem the occurrence of a secondary concentric strand in the periphery of the cortex, which appeared to be the remnant of a once normal system of nude strands; and in *Ceratozamia mexicana* the vertical succession through the pith of a large stem of effete peduncular cylinders the peduncles which successively terminate, the stem being in turn pushed to one side, and their basal region enclosed by a lateral shoot, which continues the main vegetative axis. In conclusion, the author endeavoured to show that certain characters in the vegetative structure of these plants showed them to be nearly allied to, or descended from, certain fossil Fern-like plants, notably the *Medulloseæ*, and these characters were: the extra-fascicular zones in the stem of *Cycas*, which really represent the outer portion of the flattened concentric strands in the stem of the *Medulloseæ*, the inner portion of which has died out; and all the various concentric structures above-mentioned. For the type of structure prevailing in the

ancestors of the *Cycads* would have been the concentric, whereas in their descendants it is the collateral. The significant outcome of this study is to form, in the vegetative characters of these plants, a connecting-link, over and above that already afforded by the discovery of spermatozooids in *Cycas* and *Ginkgo*, between "flowering" and "flowerless" plants. Dr. D. H. SCOTT, F.R.S., in criticising the paper, referred to the importance of certain facts which had been elucidated by the author, and which he himself was able to confirm.

ROYAL HORTICULTURAL SOCIETY.—"The details given on p. 48 of the Society's 'Arrangements, 1898,' in reference to The Sherwood £10 10s. Silver Cup for Annuals and Biennials, do not appear to some people sufficient, and various applicants have asked the following questions, which, with their answers, the President and Council would be greatly obliged by your kindness in publishing for the information of others:—"

Q. "The contents of each tube must consist of one variety only." Am I to understand that *Coreopsis grandiflora* and *C. Drummondii*, or *Nasturtium* "Cloth of Gold" and *N. "Crimson King,"* and so on, may not be exhibited in the same tube? A. They may not.

Q. Are the tubes "not to exceed 3 inches diameter at the top side?" A. They must not exceed.

Q. "The vases must be provided by exhibitors, and must not exceed 6 inches in diameter inside." Does this apply to the "plain glass vases" only? A. Yes. The tubes must not exceed 3 inches, nor the vases 6 inches.

Q. Who provides the tubes? A. Exhibitor, unless he is content with the stoneware-jars the Society provides at all times.

Q. Will Regulation XI. be enforced—"All specimens must be the *bonâ fide* property of and grown by exhibitor"? A. Yes.

Q. Must exhibitor stage (i.e., arrange) his own exhibit, or may he call in professional help? A. A special person may not be procured for this special purpose, exhibitor or his gardener, or some member of the family of either, must arrange exhibit.

Q. Can the exhibit be repeated? A. Yes.

Q. Will other foliage be allowed? A. Only the foliage of the variety itself.

Q. May grasses be mingled with flowers? A. No.

HORTICULTURAL CLUB.—The twenty-third annual house dinner of the club was held on Tuesday, the 8th inst., when there was a larger gathering than on any previous occasion. The chair was occupied by Sir J. D. T. LLEWELYN, Bart., M.P., chairman of the club. There were also present Mr. Harry J. Veitch, Vice-Chairman; the Rev. W. Wilks, the Rev. Joseph H. Pemberton, Messrs. J. Gurney, Fowler, and J. Hudson (newly-elected members of the Council of the Royal Horticultural Society), James Walker, Geo. Bunyard, Geo. Monro, C. J. Wise, Peter Kay, Harry Turner, J. Asbee, J. R. Featherby, A. Goodinch Williams, G. Paul, H. J. Pearson, Charles Pearson, Philip Crowley, A. Watkins, J. Sweet, R. Gorton Salmond, H. T. Armitage, R. Ritches, &c., and the Secretary. Mr. Geo. Bunyard arranged for an excellent selection of instrumental and vocal music to be given during the evening; an admirable dessert was provided by the kindness of Messrs. Geo. Monro, Asbee, and Peter Kay, while the tables were beautifully decorated with flowers and plants from Messrs. J. Veitch & Sons. The usual toasts were given, and altogether a most successful meeting took place. The condition of the club was stated to be very satisfactory, and several new members were added.

CHESTER PAXTON.—At the usual fortnightly meeting, held in the Grosvenor Museum on Saturday last, Mr. C. FLACK, of Cholmondeley Castle Gardens, read an able and instructive paper entitled, "Grape Growing for a Private Establishment." Mr. FLACK, who is a recognised authority on Grape-growing in Cheshire, dealt extensively with the subject, entering fully into all the details of treatment and cultivation of the Vine, and gave a list of the best and most

useful varieties for keeping up the season's supply. An interesting discussion followed the reading of the paper.

KEW GUILD.—The annual general meeting will take place on Thursday evening, February 24, at 8 o'clock, in the Lecture Room, in the Royal Gardens. Entrance by Melon-Yard Gate.

NATIONAL CHRYSANTHEMUM SOCIETY.—The Second Annual Smoking Concert in connection with the above Society took place at Anderton's Hotel, Fleet Street, the object being the benefit of the Reserve Fund. The room was delightfully decorated by plants kindly lent by Messrs. W. Cutbush & Son, Highgate Nurseries; the floral decorations were carried out by Mr. D. Ingamells. The chair was taken by Mr. James H. Veitch, F.L.S., supported by his brother Mr. J. G. Veitch and friends, the large room being filled to overflowing, a considerable number of ladies being present. An excellent and varied programme was provided, and at its close a vote of thanks was given to the chairman, proposed by Mr. Richard Dean, V.M.H., seconded by Mr. Brian Wynne, his health being also drank with full musical honours. The proceedings were brought to a close, by singing "Auld Lang Syne."

NEW PLANTS.—A descriptive list of the new garden plants of last year has just been issued as Appendix II. of the *Kew Bulletin*. A similar list has been prepared and published in the same way annually at Kew since the year 1888. These lists are useful as a guide to the correct names of plants, and as fixing the date of their introduction into gardens. They include not only plants brought into cultivation for the first time, but the most noteworthy of those which have been re-introduced after being lost from cultivation. Other plants included in the list may have been in gardens for years, but either had not been described or their names had not before been authenticated. Only species, botanical varieties, and hybrids with botanical names, are included. The list is compiled from all the botanical and horticultural publications in which new plants are known to be mentioned. The name and that of its author are given, the place of publication is cited, with a brief description of the plant, its habitat, and the name of the garden into which it was first introduced. The total number of new plants enumerated in this last list is 338. They include 160 Orchids, 8 Ferns 48 stove plants, 34 greenhouse plants, 77 hardy herbaceous plants, and 11 hardy trees and shrubs. As usual, Orchids are by far the most numerous; among them are 25 Cypripediums, 25 Cattleyas, 10 Dendrobiums, 12 Lælio-Cattleyas, 8 Miltonias, and 13 Odontoglossums. The list may be had from any bookseller, or from the Royal Gardens, Kew, price 4d.

"LA SEMAINE HORTICOLE."—The number for February 12 is entirely devoted to an account of the career of the late JOHN LINDEN, and the ceremonies observed at his funeral. The most valuable portion of this biographical document are the account of his travels in South America, and the long list of remarkable plants introduced by him. These alone should ensure the preservation, in our libraries, of what is no ephemeral production. The filial piety of the son, so pleasant to witness during the life of the father, has touchingly manifested itself now that the grave has closed over the energetic man whose loss will be felt by botanists and horticulturists throughout the world.

M. C. BALTET.—The Russian Government has conferred the decoration of the Order of St. Anne on M. CHARLES BALTET, of Troyes, in recognition of his important work in pomology and allied subjects, appreciated in Russia for more than thirty years. M. BALTET, when the telegram announcing the fact was received, was presiding over a meeting of the horticultural section of the Universal Exhibition. The news was received with cordial acclamations.

CATTLEYA ACKLANDIÆ ALBA.—The succession of law-suits in reference to this plant has been so far settled in favour of Mr. ASHWORTH, the purchaser, who is adjudged by the Court of Appeal to receive £50. It is possible the case may be carried

one step further, to the House of Lords, so that no comment is at present desirable. As the case is one of great importance, and will probably in the future be cited as a precedent, we append in another column the *Times* report of the case in full (see p. 118), reserving comment of our own till we know when the lawyers have finished their work.

LOUGHBOROUGH AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—On Wednesday evening, February 9, the members of the above Association attended a lecture on "Plant-food," by Mr. E. LUCKHURST, Lecturer to the Derbyshire County Council, and Horticultural Instructor to the Midland Dairy Institute, Kingston-on-Soar, Mr. A. HEMSHIRE, gr., Beaumanor, in the chair. The lecturer dealt with the condition of the soil in regard to the growth of plants, and its manipulation, manures, &c., illustrating the subject with the aid of the blackboard.

SHROPSHIRE HORTICULTURAL.—The annual meeting of this Society was held at Shrewsbury last week, the financial results of the year were laid before the members. The receipts (which were the largest the society has ever taken) amounted to £4517 4s.; the expenditure to £3384 10s. 3d., thus leaving a gross profit on the summer show of £1130. The amount the Society paid for prizes including medals during the year amounted to £982 1s. Hearty votes of thanks were given to the Fruiterers' Co. of London for their splendid medals, and also the Veitch Memorial Trustees for their medal and prize. T. F. KYNNESELEY, Esq., was elected president for 1898. The schedule for the coming year was passed, the prize-money being nearly £1000.

THE DOG ROSE AS A STOCK FOR ROSES.—It is asserted by some American cultivators that this stock is inclined to rest during the winter, and on that account unsuited for Roses which are to be forced into bloom at an early date. This idea is regarded by others as imaginary, and they hold that the scion has as much or more to do with the inclination to rest as has the stock. What are the opinions of Rose-growers on this side?

TOBACCO-DUST.—Referring to the Rev. C. WOLLEY DOD's article on this subject, Messrs. CORBY & Co., 13, Finsbury Street, E.C., write, that they have been makers of this since 1866, and that it is quoted in their wholesale price lists, which are in the hands of most seedsmen.

MARRIAGE OF A LADY GARDENER.—The Hon. ALICIA AMHERST, the authoress of the *History of Gardening*, and the only lady member of the Worshipful Company of Gardeners, was, on the 16th inst., married to Mr. EVELYN CECIL, nephew of the Prime Minister. The Worshipful Company, as in duty bound, presented a bouquet, and the Orange-flowers were furnished by Miss. WILLMOTT, V.M.H.

PUBLICATIONS RECEIVED.—*The National Dahlia Society Annual Report.*—*The Gardener, February—Proposed Revolution in the Science of Meteorology*, by W. G. Wenley, Chelmsford.—*Orchid Review.*—"Jevremovac," exchange list of seeds of the Botanic Garden, Belgrade, Professor St. Jaksic, Director; Z. Jurisic, Curator.—*Wilts County Council Report on the Calne Agricultural Demonstration* (Eyre and Spottiswoode).—*The Flora of Berkshire*, by G. C. Druce, M.A., Oxford, at the Clarendon Press.—*The Culture of Vegetables and Flowers . . .* by Sutton & Sons, Reading, 7th edition (Simpkin, Marshall, & Co.).—*A Flower-hunter in Queensland and New Zealand*, by Mrs. Rowan (John Murray).—*Twenty-first Annual Report, Connecticut Agricultural Experiment Station*, 1898.—*Blotter and Diary*: together with an account of the Chinchas Guano Islands, by The Anglo-Continental (late Ohlendorff's) Guano Works Co.

KEW NOTES.

PITTOSPORUM BICOLOR.—Flowering branches of this rare and distinct species of *Pittosporum* have lately been sent to Kew by Mr. Begbow, the gardener at

Abbotsbury Castle, where it has formed a dense shrub 18 feet high in the open air. It is a native of Victoria and Tasmania, ascending to 4000 feet in the latter island, where it is said to always grow in shady ravines, or shady places on the sides of rivers and streams in rich, moist, alluvial soil. It attains a height of from 20 feet to 40 feet, with a trunk 1 foot in diameter, and flowers in October and November, afterwards ripening an abundant crop of red drooping berries about the size of Peas. A form of it is figured in *Regel's Gartenflora*, vol. i. (1852). The Abbotsbury plant has numerous short branches crowded with linear-lanceolate leaves from 1½ to 2 inches long, the margins revolute, the upper surface dark green, the underside clothed with felt-like wool. The flowers are solitary in the axils of the leaves, the pedicels being ½ inch long, and the tawny-yellow and red corolla is ¼ inch long. It is an interesting evergreen for the warmer parts of the kingdom, and is worth a place among curious plants for the conservatory.

VACCINIUM GLAUCO-ALBUM.

A plant of this comparatively unknown species has lately been sent to Kew by Mr. Thomas Acton, in whose garden at Kilmacurragh, Rathdrum; it is quite hardy, forming a dense shrub with angular branches, whorled, bright green, leathery, corrugated obovate leaves 2 inches long, the margins serrate, the underside white. Its flowers are produced in dense axillary racemes 3 inches long, with large white persistent bracts, and egg-shaped white and pink corollas ¼ inch long. It is a native of Sikkim Himalaya at an altitude of 10,000 feet, where it was discovered by Sir Joseph Hooker. It belongs to the same section of the genus as *V. serratum*, which is cultivated in the temperate-house at Kew, and which is represented in the *Botanical Magazine*, t. 5103 (var. *leucobotrys*). *V. glauco-album* will probably require protection during winter—in the colder parts of this country, at any rate. W. W.

HOME CORRESPONDENCE.

THE ROYAL HORTICULTURAL SOCIETY'S COMMITTEE AWARDS.—No doubt presently, when the matter comes to be dealt with in a practical and sensible way, the subject of medal and certificate awards by the various committees can be satisfactorily settled. Had the Council invited a conference with selected representatives of the three committees prior to issuing any communication of the nature published in the *Gardeners' Chronicle* recently, the matter might have been determined without irritation. But the proposed arrangement, whereby the committees shall appoint a small number from each body to deal with their own respective groups or exhibits, furnishes no guarantee that there will be any reduction of medal awards. On the other hand, were it ordered by the Council that no certificate or merit award be made by any committee except on a vote of two-thirds majority of all the members present, then a change would soon result. The Fruit Committee, at its first meeting this year, awarded two First-class Certificates, a most unusual circumstance; but then, these were awarded to standard fruits that may be in wide cultivation fifty years hence. An Award of Merit was, however, made by a vote of, I think, six to four—an absurdity when twenty-two members were present. Under the rule advised, to carry this award the majority should, excluding the chairman, have been fourteen. Had that been the rule, the award would not have been made. Whether this proposed rule would work with the Floral Committee or not, it would with both the Fruit and Orchid Committees, as their range of subjects is much more limited. I draw attention to the fact that in the *Gardeners' Chronicle* alone is published the return—evidently a belated one—of the medal awards made by the Hybrid Committee on the 6th inst. There are ten such awards, and of these, three only are to amateurs, the remaining seven being to the trade. That represents, I believe, a fair average result of the Drill Hall meeting awards. But still there were collections or groups exhibited by four other members of the trade, all as well worthy of medals as some of those that were subjects of awards, and that number raises the proportion of trade exhibits materially. It is thus evident that by far the larger number of the Drill Hall medals certainly fully two-thirds, if no more during the

year go to the trade. To go on as before, granting them of course with judgment and discretion to amateurs, can do no harm, and would leave little room for cavil. As to the trade groups, I would suggest to the Council that the Award Committee make no medal awards to these, but only marks or points, the maximum of which and the basis of granting them, shall be duly specified. Then at the end of each year these marks or points shall be placed to the credit of each trade exhibitor, and one gold medal, which would be taken by the same trader once in five years only, with silver medals of substantial value, should be awarded according to the number of points gained during the year. How many medal awards would that method save, and how highly prized would be the annual medals when won! I am not sure whether it would not lead to a very healthy competition on the part of the trade to obtain what would then be real honours. A. D.

MORISIA HYPOGÆA.—In reply to my friend, Mr. Arnott, I may say that it is quite possible to get seed from *Morisia hypogæa*. I had the plant for several years, and failed to get any seed. I then determined to practice the maxim Max Leichtlin once gave me—"You can get seed from almost anything, if you'll only take the necessary trouble." Each day I visited the plant armed with a camel's-hair brush, and dabbed it into flower after flower. The result was, that presently the stalks began to bend over, and buried the swelling pods deep down among the foliage. Eventually I got quite a nice crop of seeds, which I am sowing this spring. In the same way I got seed from *Tecophilæa cyano-crocus*, *Lithospermum Gastoni*, and other choice things. The brush evidently supplies the place of some fertilising insects which we have not got here. Arthur K. Bulley, West Kirby, Cheshire.

AN OLD TREATISE ON THE DAHLIA.—In the *Gardeners' Chronicle* for May 22 last year, I gave a short sketch of Dahlia bibliography. Quite recently a friend in America has forwarded me a copy of a curious little treatise, with the existence of which I was not previously acquainted, bearing the title of *A Treatise on the Culture of the Dahlia and Cactus*, by E. Sayers, author of the *Flower-garden Companion*, &c., which was published in Boston, U.S.A., as far back as the year 1839. It is 6 inches by 4 inches in size, and has stiff cardboard covers, and consists of seventy-two pages, the first forty-eight of which are devoted to the Dahlia. The author acknowledges his indebtedness to the works of Paxton and McIntosh, and has probably adapted much of their teaching to the requirements of American growers. Besides a brief survey of the history of the Dahlia, a descriptive list is given; and I only draw attention to the work now by way of complementing my former observations on the subject, and especially as Sayers' treatise is almost, if not wholly, unknown to present-day English growers of the Dahlia. C. H. P.

THE PRUNING OF FRUIT-TREES.—I do not pursue the matter of pruning without good reasons, it being an important subject. Mr. Kettle's remarks on p. 74 do not answer my questions. I do not understand what Mr. K. means by "pruning to a certain number of inches" "which will not always work." Where did Mr. K. read anything I said about any number of inches? Certainly not on p. 45, where my questions will be found, but which are not answered by Mr. Kettle. He quotes what was said about Pitmaston Duchess on the Pear stock, "side by side with another on the Quince," one of 8 feet, the other 3 feet, yet both bear fruit; and why not? still I say, let me have the tree first, and afterwards the fruit. What of the concluding remarks, that "pruning tends to multiply branches close home," and so on—why, the very thing to make a tree shapely. Mr. K. will some day learn that the habit of fruit trees varies with the variety, yet all shoots when a tree is young should not be pruned to any particular number of inches, but according to their strength, and the form the tree is to take—standard, espalier, fan, or cordon. If the absence of pruning will accomplish these ends, then I have a great deal still to learn. Does Mr. K. assert that a fruit tree will develop into as shapely a tree without as with pruning? Charles Hott.

LAUDANUM.—A year or two ago I raised the question in the *Gardeners' Chronicle*, when and why was the name Laudanum transferred from the gum of the *Cistus* to a tincture of opium? That laudanum, ladanum, labdanum, are different ways of spelling the same word there can be no reasonable doubt. Clusius, writing in the sixteenth century (*Rariorum Plantarum Historia*, p. 81) says "the gum of the *Cistus* is

called 'in Greek and Latin Ladanum, and in shops Laudanum.' Skeat (*Concise Etymological Dictionary*, p. 239) fully discusses the word Laudanum, and shows that it is certainly the same as Ladanum. Whilst recently reading the "Life of Paracelsus" in the *Penny Cyclopædia*, I found that this alchemist, before the middle of the sixteenth century, was the inventor of a wonderful panacea, which he called Laudanum. In the dictionary at the end of his biography it is thus described:—"Laudanum Paracelsi est medicina laude digna, ex duabus tantum rebus constans, quæ morbos fere omnes curabat." As the same biography tells us that Paracelsus was the first to bring opium into general use as a medicine, and as the composition of Laudanum was kept by him a secret, it is highly probable that it was a mixture of opium and the gum of the *Cistus*, which would operate powerfully as an anodyne, and become as universal a popular remedy as chlorodyne at present is in France. The words *laude digna* in the above passage show the probable origin of the absurd derivation *laudanum*, i.e., "to be praised," which we find given for *laudanum* in almost all old dictionaries. C. Wolley Dodd, Edge Hall, Malpas.

PEACH AND NECTARINE TREES AT CALLIS COURT.—Some of the best and healthiest Peach and Nectarine trees which have come under my notice I saw in the gardens of H. Marks, Esq., Callis Court, Broadstairs. They are planted against a wall, which they cover for a distance of 100 yards. The trees have certainly been planted too closely together, being only 12 feet apart, but rather than take out each alternate tree the wall has been raised about 4 feet, thus affording space for the upward extension of the branches, and averting the necessity for much restrictive pruning so detrimental to the well being of the Peach. The gardener, Mr. Richardson, lays in the shoots thinly and evenly over the trees, and these give great promise of a crop the current year. The varieties consist of many of our very best and most profitable kinds, including Waterloo, the best early Peach, and some of the best late varieties; the only variety which does not succeed at Callis being Golden Eagle, for although the tree bears well, the flavour, I was told, is inferior. H. Markham.

GALANTHUS GRANDIFLORUS.—I am sending you some flowers of *Galanthus grandiflorus*, which I think you may like to see. It was described by Mr. Baker in the *Gardeners' Chronicle* of March 25, 1893, under the name of *G. maximus*, and since changed by him to *grandiflorus*, as he found there was already a *G. maximus*. The first name would have been more descriptive of this form, as though the flower is fine its striking feature is its very robust habit of growth, with very long flower-stalks, which are thick and strong, and stand well up. Though like *G. plicatus* in the leaf, patches of these varieties growing side by side look very different. R. O. Backhouse.

WILLIAM CATTLEY.—Mr. Hemsley is a little premature in saying that we do not intend to include Cattley in the supplement to our *Biographical Index*. He will probably appear there, although his claims to insertion are very slight; and I confess Mr. Hemsley does not, to my mind, show any good reason for including him. With reference to Van Braam's *Icones Plantarum*, it may be noted that the lithographs were done by Charles Henry Bellenden Ker, whose initials are attached to some of them (see *Pritzel*, 10,779; and *Biogr. Index*, p. 96). Jas. Britten.

STERNBERGIA MACRANTHA.—The fact that *Sternbergia lutea* does not flower freely in every garden is pretty well known; and it is to be feared that *S. macrantha*, figured on p. 97 of the *Gardeners' Chronicle*, will not prove more accommodating. Mr. Edward Whittall, of Smyrna, sent some bulbs of this fine *Sternbergia* to this country a few years ago, and I was indebted to him for several bulbs, and succeeded in flowering them under glass the first season. Planted out I have, however, been unable to flower it, although it is apparently quite hardy. I believe it will require a thorough "roasting" in summer in most parts of the country. S. Arnott, Carsethorn, Dumfries, N.B.

CALANTHE VEITCHI.—I read with interest "W. R., Cadlands" remarks at p. 104 of the *Gard. Chron.* about the rather abnormal flowering of his plants of *Calanthe Veitchi*, as my own experience chanced to be similar, and it occurred two years in succession. In one case the flower-spike was more than 3 feet long, measured from the base of the pseudo-bulb, one break at the first leaf-joint, and another at the

apex of the spike. In another case a bulb had two large flower-spikes, which came from the base of the pseudo-bulb, and one from its apex. In both instances the terminal flower-spikes were small, as they were pinched off before the flowers expanded. The pseudo-bulbs were very large, and the abnormality was probably due to their being fully matured. I had a plant of *Calanthe vestita* which produced two flower-spikes at the base, and one on the top of the pseudo-bulb, where the one joint is not exact at the apex, as in the case of *C. Veitchi*. C. Branson, Gardener, Coleshill Park.

NOVELTIES IN CHRYSANTHEMUMS.—On p. 4 of the late issue of the *Gard. Chron.*, you published under the head "Novelties in Chrysanthemums" and signed E. Knowles, a communication which I almost word for word a copy of a note from my pen, which appeared in the *Gardeners' Magazine*, on p. 82 of a late December number in 1897. I enclosed cutting, which please return, which will prove to you what I say, as a clerical error which I corrected, also appears in your correspondent's somewhat smattering piece of work. W. H. Lees. [The communication was sent to us in the ordinary way by Mr. Knowles, of the Gardens, Yewden Manor, Henley-on-Thames. We were entirely ignorant that the note was substantially a copy of a communication of Mr. Lees, that had previously appeared in the *Gardener's Magazine*. We have been grossly imposed on, and all we can do is to express our great regret to our cotemporary, to Mr. Lees, and Mr. Wells, and any one else concerned. Ed.]

VALUABLE LATE APPLES.—In this neighbourhood I still find none to surpass Newton Wonder and Royal George, which are equal in every way, I think to Bramley's Seedling or Prince Albert. The last named, however, is a grand Apple, and I enjoy it as a dessert fruit. Newton Wonder, the Derbyshire Apple (raised, I believe, at King's Newton), I find no trouble in selling at 25s. per cwt. (a price that I also obtain for Royal George). I am sending you sample of Newton Wonder, Royal George, and Bramley's Seedling. All the best fruit have gone, and those I send are ordinary examples. They were cultivated near to each other, Bramley's Seedling having the sunniest spot, Royal George next, and Newton Wonder in the lowest ground on a sunny slope. Geo. Bolas, The Gardens, Hopton Hall, Wirksworth, Derbyshire. [The fruits are very commendable and well preserved. Newton Wonder is undoubtedly a first-class late-keeping kitchen Apple, and it succeeds capitally in the Midlands, and equally so in Kent. Royal George was shown by Scott of Merriott at the Royal Horticultural Society's Apple Conference, and is described in the report of the proceedings, but we fail to find it mentioned in Dr. Hogg's *Fruit Manual*. The fruits are of moderate size, very solid, have little core, and on one side are coloured similarly to the Beefings. Ed.]

THE PREVAILING MILDNESS OF THE WEATHER.—Whilst looking round our nursery to-day, we noticed the variegated Hollies to be growing, many of the silvers having as much as 2 inches of new growth upon them. The Daffodils are also forward, but, perhaps, the most remarkable of these bulbs was the white trumpet Narcissus, Mrs. Thompson, which has leaves 12 inches high, and was showing flower buds; and *N. poeticus præcox* are 8 inches high and showing for bloom. This variety of Pheasant's Eye being always the earliest, and this year it is earlier than usual. The nursery is 600 feet above the sea level, and lies 6 miles west of Birmingham, so that the situation cannot be considered a very warm one. Pope, Birmingham. [As touching upon this feature of the season, we received from the head gardener at Enville Hall, Worcestershire, some young shoots and leaves of the Horse-Chestnut, the former measuring 4 inches in length, and the latter 8 inches in greatest width. Ed.]

—In 1856 just such a mild winter as the present one was experienced, and at the end of the month of January vegetation was very forward. But a different state of things prevailed at the end of February, and during March cold easterly winds, and sharp black frosts occurred with an almost entire absence of sunshine. On March 10, a keen frost set in which increased in severity on the 11th and 12th, and caught many gardeners napping, and caused much destruction of early crops. Apricots that were in full bloom suffered greatly; one night the mercury fell to 22° Fahr. The bitter experiences of gardeners in 1856 may be repeated in 1898, but to be forewarned is a measure to be forearmed, and by retarding instead of forwarding outside crops, and by having plenty of

protecting materials at hand ready for immediate use such as a good big heap of strawy stable-litter, dry fern and hay, frigidomo, canvas, mats, &c., and a lot of pliant hazel rods for forming bows to support heavy coverings. R. D. [The gardener will be prepared for whatever may happen. ED.]

FREESIAS.—Having read with much interest the notes, in which Mr. Kerry has written inquiring if

PASSIFLORA EDULIS.—I am pleased to see the figure of *Passiflora edulis*. When I was a young gardener in a private place near Southampton, about the end of the "forties," there was in the garden a somewhat lofty lean-to greenhouse, and at the back of it there had been planted the true form of *P. edulis*. The house had an old-fashioned plant-stage, with shelves rising tier above tier, but with a walk behind it, and a narrow border against the wall. In

— I am much interested in the correspondence which has recently taken place in these columns respecting the above, as I had cultivated the species and fruited it for many years. I had it trained on the back wall of a late lean-to vinery at Longford Castle, its roots being confined to a narrow border. The illustration of fruit and leaf given in last week's *Gardeners' Chronicle* is a very good one. The shell-like epidermis containing the seedy, Tomato-like pulp, was of a dark-purplish colour, when ripe, as described, and the pulp highly perfumed, and has a pleasant acid flavour. All the same, I am in agreement with the editorial note, "something to suck, but little or nothing to eat." The plant is propagated from seeds or cuttings in warmth. The annual shoots that are not wanted for further extension should be cut back to the old wood, and the latter trained thinly over the wall or along the supports near the roof. The wall is, in my opinion, the best place for *Passiflora edulis*, a place on the roof being too valuable to be occupied by a mere novelty in the way of fruit. H. W. W.

LÆLIA ANCEPS WADDONIENSIS.—There is an error in your report of the Royal Horticultural Society's meeting in respect to the variety of *Lælia anceps* then certificated. It was entered in the Society's book as *L. a. Waddoniensis*, and as such it was labelled, so that I am at a loss to know how it got named *Crowleyana*. J. Harris, *The Gardens, Waddon House, Croydon*. [Our representative informs us that the name was altered several times in the Drill Hall, and the one given in the *Gardeners' Chronicle* report was thought to be the final one. ED.]

MADRESFIELD COURT GRAPE.—We have heard but little recently of the splitting of the berries of this valuable Grape, one of the very best black varieties grown. Some years ago it was thought by many gardeners that the variety would fail to become a favourite Grape for private gardens, seeing the unfavourable reports concerning the berries cracking that appeared from time to time in the gardening press; but now almost everyone is speaking in its praise. With respect to the cause of the splitting there were various opinions, and various plans recommended for its prevention, some recommending the withholding of water at the roots, but experience teaches me to afford plenty of water; and I often thought that where the splitting was prevalent, it might be traced either to dryness of the soil, or something that checked the development of the berries, and consequently the skin. It is a well-known fact that a cool, moist atmosphere in a vinery will cause the berries of several varieties to split, but that was not the case with Madresfield Court—at any rate, not in every instance. As one preventative, a little warmth should be maintained at all times in the eating apparatus; and when the berries are approaching full size, the air of the vinery should not be kept very moist, and the danger is greatest in close, cloudy weather. H. Murkham.

BLenheim PIPPIN APPLE AT RUXLEY LODGE.—I believe tradition tells us that this famous Apple was raised at Woodstock very early in the present century. That a claim is put forward as to such suggested origin there can be no doubt, but all the same, this said Woodstock seedling might have been but a natural reproduction of a variety long in existence. I was tempted, of course, by the evil demon of scepticism to think so much the other day, when looking at a wonderfully old horizontally-trained tree of the variety in the old monastic, or lower kitchen gardens, at Ruxley Lodge, Esher. Mr. Miller assured me that it was the true Blenheim Pippin, or Orange. The stem of this interesting and aged tree is, near the ground, about 2 feet in diameter, and to a large degree seems to be hollow. Almost solely there runs off on either side one huge branch to a great length, which is, as is usual, densely studded with spurs on the upper side, and produces at the extremities stout growths, which show how much of vigour there is in this very old tree. In estimating the age of this tree, we are bounded by the assumed somewhat modern origin of Blenheim Pippin, and therefore conclude that it may not exceed some sixty to seventy years; but if no such bounds be set to the estimate, then the tree might be regarded as fully 150 years old, an estimate that is not far-fetched, seeing that these kitchen gardens have been in existence for over 300 years. The point naturally raised is this—Prior to the raising of the Blenheim Pippin, was there any variety in existence of which the former could have been a natural seedling and a reproduction? Seeing that from time to

FIG. 54.—ASPHODELINE ISTHOCARPA: HEIGHT 5 FEET. (SEE P. 111.)

any other reader has obtained more than eleven individual flowers upon a spike, I am sending you on some with twelve, but you will see that they are not all open. We have had several spikes this season with twelve flowers on them, and the highest number has been fourteen. In regard to the number of flowers to one corm, we have counted thirty-eight, but that spike had three laterals. I enclose one spike which has developed four laterals. W. L., Rood Ashton Gardens. [Fine trusses of great strength. ED.]

this the *Passiflora* had been planted, and it had covered the back wall and a portion of the roof of the house, rendering hard pruning necessary every winter. This plant flowered and set its fruit freely. The bright purple fruit was in much demand for dessert. I used occasionally to cut one open, and sucking it, enjoy the pleasant acid taste of its orange-coloured pulp. I have never since witnessed such a fine example as this, and I sometimes wonder if the specimen is still in existence, R. Dean.

time numerous Apples have been raised from seed that have proved to be mere reproductions of the parents, is this hypothesis in relation to the Blenheim Pippin an impossible one? *A. D.*

VENTILATING GLASSHOUSES.—I have on many occasions observed the way some young gardeners proceed to afford air to glasshouses, and my object in writing this note is to show that the methods of doing it is not always a safe one to follow. The man in charge makes it a rule to always consult the thermometer hanging in the house, and unless it indicates exactly 65°, 70°, or whatever the given maximum may be, they will not open a ventilator. Now I do not regard this as quite right, more especially for fruit-houses. The kind of thermometer I would advise him to watch is the sun, and the minute its rays touch a fruit-house roof, and rather before if possible, when the sky is clear, the upper ventilators should be opened a small space, gradually increasing it as the sun's rays cover the house. By following this method, which is always noticeable, the house has not the steamy look if ventilation be not afforded till the thermometer in the house registers the exact maximum figures. It will be noticed that when the sun has shone on a house for a period of two or three minutes, the temperature springs up nearly 10°, often before any one could reach the house, and such sudden increase of temperature has an injurious effect on Vines and other fruit. It is a judicious plan to shut the valve of the flow-pipe, which is generally done unless the weather is very fickle; then it is preferable to leave the valve wholly or partially open, this ensuring a more uniform temperature with the ventilators opened. It is also a safe method with fruit-houses which face the east to leave a small space for air entering the house during the night in hot weather; for if a man is about soon after 5 A.M., by adhering to these rules, we should very rarely have scalded berries or shoots. *A. J. Long, Wyfold Court Gardens.* [We have our doubts about the position in the vinery or Peach-house of the thermometer. It may be right to hang an instrument 5 feet from the glass if we wished to ascertain the average temperature of the air in the house; but what we most need to know in spring and summer is the temperature of the air within a space of 1½ foot of the roof-glass. *Ed.*].

A PIER-HEAD ROSE SHOW.—The Southampton Horticultural Society seems to have an executive determined not to be overborne by difficulties. It is in that respect rather diverse from a similar society in London which seems to exist only to be the creature of a greater power. Last year seems to have seen the last, for the present, at least, of its long series of great general summer exhibitions, and that could be held only under adverse conditions, such as it needed immense energy to surmount. This year it has boldly resolved to take a different course, and will hold a grand Rose show on June 28 and 29 next, instead of the customary late summer exhibition. But the odd thing concerning this Rose-show is, that it will be held in a pavilion set up at the end of the pier. The spot is easy of access from steamboat-pier and railway-station, and the pier authorities have agreed to allow exhibitors and their exhibits to pass free of toll. That our great Rose growers will support it is naturally hoped, especially that Southampton hitherto has not seen the queen of flowers yet in all her regal beauty. *A. D.*

DEGENERATION OF ORCHIDS.—There is sound common sense in what Mr. de B. Crawshaw has written anent this subject, and especially in his last paragraph, where he notes the fact that Orchids passed from hand to hand seldom benefit by the change. And no better proof of the truth of this can be adduced than the fact that in the majority of instances one sees of fine specimen plants up and down the country these are of easily grown kinds. Large specimens of *Coelogyne cristata*, *Dendrobium nobile*, and some of the more easily grown distichous-leaved kinds are common enough, though they may have changed hands a score of times, but let a fine plant of some of the more miffy subjects go from one collection to another, and deterioration soon sets in. Nor is this always the fault of the cultivator. There is not the least doubt that situation has a lot to do with the successful growth of certain kinds. In one garden I could grow *Vanda cœrulea* well, but I took the same specimen with me to a different part of the country, where new houses had been specially erected for them, and the plants went back from the first, and although I have tried them in various temperatures and had a fair amount of

success, the plants have never had the same vigour or produced such fine spikes as formerly. But speaking from one's own experience is not always to take a broad view of the subject, and it is sometimes instructive to note how plants thrive elsewhere. Anyone who has had charge of a large collection for a number of years knows well that in certain parts of a house certain plants thrive, and there one is careful to keep them. One knows well enough that the plants would not do so well in other places, though possibly he would be at a loss to say why. For this reason, although doubtless we cannot be too well informed of the conditions under which the plants grow naturally, it does not always do to follow these conditions exactly. For are not many kinds greatly improved under cultivation, and have we not sufficient evidence that Orchids deteriorate even in their own habitat? The amount of information given by interested collectors as to habitat, climate, and natural surroundings, has never, I am sure, done one-tenth of the good that the knowledge of the behaviour of the plants under cultivation disseminated through the gardening press by those who have studied this want has done, and, though glad to see such notes as that by Mr. Lowrie, who, by the way, is presumably not a collector, I think that cultivators now-a-days are able to hold their own with Orchids, as well as with any other family of plants. *H. R. Richards, Coldham Hall Gardens, Bury St. Edmunds.*

MARKET GARDENING.

ORCHARDS IN VICTORIA.

THE area now under orchards in Victoria amounts to 48,000 acres, and under Vines 36,000 acres. A very large area has been planted with Apples during the past three or four years, with varieties suitable for the British market, and a large export trade is expected when the new orchards are all in full bearing. The soil and climate are well suited to the production of almost every known variety of Apple and Pear. Fifteen months ago the Department of Agriculture forwarded to me fifty-five varieties of Apples, and fifty out of this number arrived here in excellent condition. The favourite varieties now being exported to London are New York Pippin (Cleopatras), Newtown Pippin, Ribston Pippin, Munro's Favourite, Baldwin, Alfriston, Bismarck, Jonathan, Adams' Pearmain, Five Crown Pippin, Dumelow's Seedling, Rome Beauty, and French Crab. Growers are very careful in grading and packing their fruit, and have studied all details in connection with the requirements of the London market. A large quantity of Victorian fruit is sold by retail shops as Tasmanian, that colony being the first to commence the export trade.

Of Pears, Winter Nelis, Vicar of Winkfield, and Broompark have stood carriage to this country better than other varieties.

A fair quantity of Grapes, chiefly Waltham Cross, Muscat of Alexandria, Almeria, and Doradilla, arrived last season. A considerable increase in exports of Apples, Pears, and Grapes is expected to take place this season, also some shipments of Apricot and Raspberry pulp. The *Cuzco* will bring the first shipment of fruit this season, and will leave Melbourne on February 22. *J. M. Sinclair.*

CROPS IN THE OPEN.

(Continued from p. 103.)

PEAS are a good paying crop, and the earlier green Peas are put on the market the more profitable are the returns. Therefore, land which is to carry a Pea-crop, should have a good dressing of decayed manure ploughed into it, and be well harrowed, and, if lumpy, rolled and harrowed again, so as to pulverize the earth before drilling in the Peas with a machine, say at from 1½ to 2½ feet from drill to drill, according to the height which the Peas sown attain under generous cultivation. Lightning is the best early Pea that I am acquainted with, a prodigious bearer of well filled pods, containing white, round Peas of fine flavour, the haulm attaining a height of 2½ feet. Last year I sowed Lightning, Tom Thumb, and First Crop the same day in the furrows of unharrowed ploughed land, and noted the results, which were in

every respect in favour of Lightning. A sowing of *Dale* (1½ ft. high) made the same time as the above-mentioned variety, would make a capital succession to it, and the large handsome pods being well filled with marrowfat Peas of fine size and quality, will realise top prices in June and the early part of July. In growing Peas for market, the items of expense incurred are, the cost of preparing the land, sowing cost of seed, and taking the crop as soon as it is ready, and sending it to market; pea-sticks for support being dispensed with. Successional sowing of dwarf-growing marrowfats should be made at intervals of a week or so from this date onwards to the middle or end of May. As soon as the ground is cleared of the Peas, it should be prepared for and cropped with Lettuce, Spinach, Cabbage, Cauliflower, Brussels Sprouts, Broccoli, Scotch Kale, and such like bearing in mind that every day that a portion of the land remains uncropped, represents money out of pocket.

Lettuce is an other paying crop when well attended to; doing well in light rather than heavy soils of average depth and fertility. Roughly estimating, one acre will yield 14,520 properly developed heads of Lettuce grown at one foot a part, and which (in the case of autumn-raised plants) being ready for market from the middle or end of May, will command a wholesale price of about one shilling per dozen—£60 10s, and putting the price for succeeding crops of this salad plant during the remainder of the year at the low price of ninepence per dozen, would amount to £45 7s. 6d., thus making a total of £105 17s. 6d. per acre for two crops of Lettuce in one year, out of which a good balance would remain on the right side after all expenses had been deducted therefrom.

Cauliflowers command a ready sale throughout the year. Dwarf compact growing varieties planted out early in March, at sixteen inches apart each way, would in round numbers give 907 dozen heads to the acre, fit for marketing three months later, and which at the moderate wholesale price of two shillings per dozen, would be £90 14s. 0d. *H. W. Ward, Rayleigh.*

(To be continued.)

LAW NOTE.

COURT OF APPEAL.

(Before LORD JUSTICE A. L. SMITH, LORD JUSTICE CHITTY, and LORD JUSTICE COLLINS.)

ASHWORTH v. WELLS

FEB. 14.—This was an appeal from an order of a DIVISIONAL COURT (Mr. Justice Day and Mr. Justice Lawrence) on an appeal from the MANCHESTER COUNTY COURT, reported in 14 *Times* Law Reports, 170. The plaintiff, an amateur Orchid grower, bought an Orchid at a sale of the defendant's collection of Orchids in June, 1895. It was warranted by the defendant as a "*Cattleya Aclandiae* alba, seven bulbs and three leaves, the only known plant," and it was knocked down to the plaintiff for 20 guineas. It had never flowered while in possession of the defendant, and it turned out after two years' cultivation by the plaintiff to be not an alba or white *Cattleya*, but the ordinary purple one, which was worth only 7s. 6d. The plaintiff having brought this action for damages, the defendant admitted liability, and paid into Court £23 2s. The County Court Judge held that if the plant had been an alba it would have been worth more than £50 at the time of the sale, but that until it showed its real nature, there was no probability that any Orchid-grower would give more than 20 guineas for it. He thought that the sum paid in was enough, and gave judgment for the defendant. The Divisional Court thought that the case ought to be tried again, and sent it back to the County Court Judge. The defendant appealed.

LORD JUSTICE A. L. SMITH said that, in his opinion, judgment ought to be entered for the plaintiff for £50. There had been a public sale by auction of a collection of Orchids belonging to the defendant. It was admitted by the defendant that one of the entries in the catalogue constituted a warranty with regard to a certain Orchid. It was as follows:—"*Cattleya Aclandiae* alba, seven bulbs and three leaves, only known plant." The purple *Cattleya* was a common plant; the white *Cattleya* was exceedingly rare, or rather, if the catalogue was correct, unknown. The plaintiff attended the sale and bought this Orchid on the faith of the warranty, for 20 guineas. If it was purple it was only worth 7s. 6d. Now what was the nature of the warranty? In his judgment, according to the true reading of the clause in the catalogue, it was a warranty by the defendant that this Orchid, when it flowered, would flower white. There was no warranty that it would flower, or even that it would live. The plaintiff therefore had to wait the ordinary course of events for the plant to flower, and in two years' time it did

flower, not, however, according to the warranty, but it flowered purple. The plaintiff complained that there had been a breach of the warranty, and brought this action in the County Court for £50. The defendant paid into Court the sum of 20 guineas, the price which the plaintiff had paid for the Orchid, and a sum of 2 guineas for interest, and a further small sum to cover the costs of the plaintiff. The real question in the case was whether the plaintiff was in law entitled to any damages beyond the 20 guineas which he had paid for the plant on the faith of the warranty. The County Court Judge thought that the plaintiff was not entitled to any further damages, and he gave judgment for the defendant on the ground that the sum which he had paid into Court was sufficient to satisfy the plaintiff's claim.

The Divisional Court had made an order that the case should be sent back for a new trial. In his opinion it should not go back for a new trial, but judgment should be entered for the plaintiff for £50. At the trial there had been abundant evidence, which was uncontradicted, that the Orchid, if it was white, was worth 100 guineas. But no one could possibly tell at the time of the sale whether it was white or not. The plaintiff had to wait to find that out, and after waiting he found that the warranty was broken.

Under those circumstances, What were the damages to which the plaintiff was entitled? It was said that he was only entitled to such damages as he could show that he had suffered at the time when the article was delivered. In the great majority of cases that was the proper rule, the market value being the chief factor to be considered. But the plaintiff in this case was, in his opinion, entitled to prove that he had suffered special damages, and he might wait a reasonable time to see what those damages were. This Orchid could not properly be said to have any market value at all. The County Court Judge found as a fact that, if it was an alba, it was at the time of the sale worth more than £50. The evidence showed that it would have been worth more than £100, but with regard to the jurisdiction of the County Court, it was sufficient to say it was worth more than £50. That finding seemed to him to dispose of the case, and he thought that the County Court Judge ought thereupon to have given judgment for the plaintiff for £50. But he went on, and proceeded to find further that until the plant showed its real nature, there was no probability that any Orchid grower would give more than 20 guineas for it.

He thought that the County Court Judge, in coming to this further finding, had misdirected himself. The warranty was that, when the plant flowered, it would flower white. The plaintiff was entitled to wait until it did flower, which did not happen for two years, and it was a mistake to say, when it did flower and the warranty proved to be broken, that the measure of damages was to be regulated by what the plaintiff had given for the plant two years before. The price which he gave was no criterion of the loss which he sustained. In his opinion, therefore, the appeal failed, and judgment must be entered as he had stated.

Lord Justice CHITTY said it had been argued that the only damages which had been sustained were represented by the difference between the value of the plant at the time of the sale and what would have been its value if it had answered to the warranty at the time of the sale. He thought that this was not a case in which that general principle could be applied. This was a special kind of warranty, and in his opinion the plaintiff had shown special damage. He thought that the first part of the finding of the County Court Judge settled the question, and that what followed gave rise to the difficulty which had been felt in the case. The plaintiff could not bring his action until he had ascertained that the Orchid bore a purple flower. He therefore agreed with the judgment which had been delivered by Lord Justice A. L. Smith.

Lord Justice COLLINS said he agreed in the main with his learned brethren, but he felt some difficulty in coming to the conclusion that the County Court Judge, in whose hands the question of damages rested, and who had found £20 to be the sum to which the plaintiff was entitled, had misdirected himself. The general principle seemed clear enough—that in cases of breach of warranty the measure of damages was the difference between the contract price of the thing sold with the warranty and the market price or real value if it could be ascertained, and any special damages following from the buyer acting on the warranty might be added. Here the action seemed to be between the value of the plant with the contingency that it might flower and the value of the plant when it had flowered. If the County Court Judge meant that, and came to the conclusion that the true value of the plant with that uncertainty was no more than the money paid into Court, he felt a difficulty in saying that he was wrong. But he was satisfied that they were not giving the plaintiff too much, and he would not differ from the judgments which had been delivered. *Times*.

SOCIETIES.

ROYAL HORTICULTURAL. Scientific Committee.

FEBRUARY 9.—Present: Dr. M. T. Masters, in the chair; Rev. W. Wilks, Mr. Bennett-Poë, Mr. McLachlan, Mr. Veitch, Rev. G. H. Engleheart, Mr. Sutton, Mr. Shea, Mr. Douglas, Mr. Michael, and Rev. Prof. Henslow, Hon. Sec.

Evolution Committee of the Royal Society.—Mr. Bateson, one of a deputation to the Society, from the Royal Society, called

attention to the existence of the Evolution Committee of the Royal Society, the object of which is to promote accurate observations of facts relating to variation, heredity, selection, and other phenomena connected with the evolution of plants and animals. A horticultural sub-committee has been appointed to further the above objects, in the hope that any persons engaged in practical horticulture may be willing to assist the committee by communicating the results obtained, and allowing their operations to be observed and recorded. The Secretary of the Scientific Committee will be glad to receive any communications.

Current Mite.—Mr. Berry gave an interesting account of the history and progress of this destructive injury, especially to Black Currants in Kent. It was first observed some ten years ago, but has now reached alarming dimensions. Miss Ormerod recommended picking off and destroying the buds infested with the mite (*Phytoptus ribis*), the cause of the complaint. This was done, but last year a sudden development occurred, when picking became useless. The "Baldwin," a very heavy cropper, was the variety most seriously attacked. The "Red Budded Naples" were only slightly affected, but this variety is not a heavy cropper, and the fruit being more readily shed, it is not so useful as the Baldwin for market purposes. Mr. Berry suggested that experiments might be carried out at Chiswick to discover which was the most resisting variety, as was done with other plants in Victoria in the Horticultural Gardens, so as to aid the fruit industry in Australia.

Mr. McLachlan gave some account of the general habits of the *Phytoptus*, remarking that this species was first noticed by Westwood some thirty years ago. It is nearly legless, and lives inside the bud, consequently it is very difficult to reach by means of insecticides. He could only recommend hand-picking, unless a mite-proof variety could be found, as they had raised more or less *Phylloxera*-proof Vines.

Mr. Michael also contributed further details, observing that all the species of *Phytoptus* were parasites, and that while many species might attack the same plant, a single species might also live on many kinds. They were excessively minute, possessing only two pairs of legs instead of eight, and always protect themselves, so that it becomes a very difficult matter to reach them, as, e.g., in the curled-up edges of leaves, and within buds. It had been found that kerosene emulsion continuously applied by spraying had been more or less effective against *P. pyri*, but acari are far less sensitive to chemicals than insects. The eggs especially have a dense cuticle, so as to render it quite impervious to chemical action of insecticides. The only chance was to repeat the process of spraying, and catch the successive broods. The only thing absolutely fatal to acarus life was boiling-water; eggs and all were destroyed at once.

Mr. Berry, in replying, observed that the remedy hitherto suggested of cutting down the shoots of the Currant bushes attacked was quite useless. Mr. Veitch suggested that analysis of the branches of the varieties affected or otherwise might reveal some differences, but Mr. Wilks expressed himself as very doubtful of any appreciable differences being attainable even if they exist. Mr. Engleheart raised the question as to whether the Baldwin variety was weaker than others through over-propagation, but Mr. Michael added that *Phytoptus* do not by any means prefer weaker plants, but are found more usually on perfectly healthy ones.

[The first mention was in our columns on April 16, 1864. In 1869, March 13, and March 27, further articles were published; and on August 7, 1869, p. 841, the late Professor Westwood gave a full description and illustration of the pest. He there mentions having observed it during the previous five years mostly on specimens coming from Scotland. Ed.]

Carnations and Caterpillars.—Mr. Douglas exhibited some grubs received from Mr. White, Wateringbury, Kent, but the species was not readily determinable without being bred to the imago stage. It was suggested that gas-lime should be used, as for wireworm, to destroy them.

Pines, Diseased.—Specimens of Scotch Fir and of Abies Nordmanniana were received from Mrs. Marshall, Skelwith Fold, Ambleside, the former attacked by the Pine-beetle, the latter by *Chermes abietis*. This insect has always proved to be very fatal to this species of Abies, and the only suggestion that could be made was to cut down the tree and burn all parts attacked. With regard to the Pine-beetle, to encourage the multiplication of insectivorous birds as far as possible might be advantageous.

Cypripedium with Fungus.—Mr. Douglas exhibited specimens with the roots badly infested by a mycelium. Mr. Veitch at once recognised it as the result of a too damp atmosphere, recording the fact that having on one occasion to make a double roof, it caused so much damp that he lost many Orchids from the same cause, but on improving the atmosphere this completely prevented any recurrence of the fungus.

Primula obconica ♀ × *sinensis*.—Mr. Shea showed a hybrid raised between these species. The flowers were pink, showing the extension of yellow from the throat, with curled petals, and bearing a decided scent of *sinensis*. The calyx, however, was entirely that of *obconica*. The general appearance was nearer that of the female parent. Mr. Shea proposes to re-cross with *sinensis*, and so intensify the features of the male parent.

Two-spined Arum.—A fine example of this very common condition was received from Mr. Thomas Bennett, The Gardens, Shavington Hall, Market Drayton.

CHIPPENHAM & CALNE HORTICULTURAL.

FEBRUARY 7.—The annual general meeting was held on the 7th inst., and was well attended. The Secretary's report gave particulars of an income of £470 15s. 7d., including a balance brought forward of £123 19s. 6d. Gate-money and subscriptions amounted to £253, and royalties £78. The expenditure was £330, of which nearly £150 was paid in prizes. The substantial balance of £140 15s. 5d. remains in favour of the society. Major Brinkworth moved the adoption of the report and balance-sheet. On the motion of Mr. Gardner, seconded by Mr. Perkins, it was unanimously agreed to ask H. H. Prince Hatzfeldt, of Draycott Park, to accept the office of President for the ensuing year.

READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

FEBRUARY 7.—On Monday, Mr. Powell, foreman at Park Place Gardens, Henley-on-Thames, read a paper before a crowded attendance of members, presided over by the President, Mr. C. B. Stevens, in the club-room, British Workman.

After dealing with the varieties most suitable for the outdoor rockery, the greenhouse and stove, and the soils best adapted for their successful culture, he impressed upon the younger members in particular the great advantage and pleasure derived from making a study of the various classes of Ferns, especially in the drying and mounting of specimens in books, which would in after years be a source of profit and assistance. At the request of the lecturer, Mr. Stanton made some very interesting remarks respecting the various varieties, the growth of the spores, and the fertilisation of Ferns, illustrating his remarks by dried specimens of Crested Ferns; Ferns with distinct fertile and barren fronds; Ferns showing the various kinds of spore arrangements whereby botanists were able to determine the genera and species of the family; specimens of peculiar interest such as the gold, silver, variegated and transparent varieties, some of which the speaker had collected thirty-seven years ago. A discussion took place, bearing chiefly on the culture of *Adiantum Farleyense*, in which Messrs. Martin, Turton, Woolford, Neve, Phipps, Bright, Tunbridge, &c., took part.

NEWCASTLE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT.

FEBRUARY 8.—The monthly meeting of this Society was held at their room, 25, Westgate Road, on the above date. Mr. JOHN BULLOCK presided over a large attendance of members.

The prize for the best pots of Hyacinths and Narcissus was won by Mr. M. LARKE, North Dene, Gateshead; and a Special Certificate was awarded to the Secretary, J. Elliot, Junr., for a plant of *Cypripedium villosum*, carrying thirty blooms. Among the other exhibits on the table was a splendid dish of Sutton's Al Tomato shown by Mr. HAYES, Ferndene, Gateshead.

Mr. J. NICHOLSON, Gosforth, read a practical paper on the Tomato, embracing its general cultivation, and dealing especially with the numerous diseases, principally fungi, which affect the plant. The paper was followed by a discussion, in which many took part. Votes of thanks to Mr. NICHOLSON, and the Chairman concluded the meeting.

DEVON AND EXETER GARDENERS.

FEBRUARY 9.—A numerous gathering of the members of the above Society took place at Exeter, on the occasion of a lecture given by Mr. F. W. E. SHRIVELL, F.L.S., of Tonbridge, Kent, entitled "Four years' experiments in the cultivation of vegetables, with and without the use of chemicals." We will afford our readers the substance of this lecture in an early issue of the *Gardeners' Chronicle*.

ROYAL BOTANIC.

FEBRUARY 12.—A meeting of the Fellows was held on the above date in the Museum at the Royal Botanic Gardens, Regent's Park, Mr. C. BRINSLEY MARLAY presiding. Prince and Princess Adolphus of Teck were nominated for Fellowship.

The Chairman, in referring to these nominations, said that the late Duchess of Teck had probably done more for the Society than any other person. Not only had she done much to increase the Society's funds, but she had also graciously given her patronage and help to their shows. He feared that the Duke of Teck was in very indifferent health, and he did not know whether he would continue to be the President of the Society, but it was very gratifying that his son and daughter-in-law were about to become Fellows.

Mr. Sowerby, the Secretary, read the first part of a paper on "Fibre Plants," illustrated by exhibits of raw and manufactured products.

HORSFORTH GARDENERS' MUTUAL IMPROVEMENT.

FEBRUARY 14.—A lecture was given on Monday evening (in a large room at the King's Arms Hotel, Horsforth) by Mr. W.

A. CLARK (of Messrs. Backhouse & Sons, Nurserymen, York), who took for his subject, "A Ramble through the Lak District;" illustrated by lime-light views.

The lecture was of an instructive character. All the principal mountains and lakes in Westmoreland and Cumberland were illustrated, different sections of the mountains inhabited by plants of various species being shown. The meeting was well attended by gardeners from different parts of Yorkshire.

NOTICES TO CORRESPONDENTS.

ABIES ETICHLERI: J. McL. This is a synonym of *Abies Veitchii*, a native of the mountains of Japan up to 2000 feet. It reaches a height, under favourable conditions, of 100 feet.

ADMISSION OF YOUNG GARDENERS TO KEW: W. O. A. You will find all necessary information on p. 56 of our issue for January 22 this year.

APPLICANTS FOR A SITUATION AT KEW: A. C. The form meant to be filled up is not that published in the *Gardeners' Chronicle* on Jan. 22, but a similar one that will be sent from Kew on application.

BOOKS: Hortus. The New Practical Gardener or Modern Horticulturist, by Jas. Anderson, not "Henderson," was published in 1872, by W. Mackenzie, 22, Paternoster Row, London, and Glasgow, Edinburgh, and Dublin. There is no recent work on table decoration; but you might pick up Miss A. Hassard's on a book-stall.

CARNATION CUTTINGS: A. B. M. The cuttings are altogether too weakly, and it will be necessary to secure stronger ones. They should be prepared much the same as you would prepare a *Pelargonium* cutting. The bottom-heat you mention is suitable, but the atmospheric heat should not exceed 70°. The best book upon the subject is *The Carnation Manual*, a cheap and useful book, published by Cassell & Co., Ltd.

CUCUMBER ROOTS: T. E. B. The roots are very badly infested with eel-worm (*Tylenchus*), for which there is no cure. You should clear out the whole soil and char it, or bury deeply in the garden, and make a new start with soil from a fresh quarter, and, if possible, fresh plants also.

DAPHNE INDICA: Amateur. All the members of the family *Thymeleae* have very tender rind, and the cuttings must be afforded water very moderately, more particularly as the leaves readily decay. The water should be poured around the edge of the pot. The best sort of rooting materials are sandy peat with a layer of pure sand on the top, or a sand-bed simply. If peat be used, it should not be pressed very firm, or there will be too much moisture for the good of the cuttings; and the crocks, broken finely, should occupy a quarter of the depth of the pot. The shoots selected for cuttings should be tolerably firm, especially the base, therefore one-year-old wood forms the best cuttings. The leaves should be removed from a cutting to the extent of one-third its length. *D. indica* strikes best in March in a warmth of 58° to 60°, and moderate bottom-heat, under a bell-glass. If grafting be desired, stocks of *D. pontica*, *D. Gnidia*, *D. Cneorum*, *D. laureola*, or *D. Mezereum*, should be raised from seeds sown in the autumn (those of *laureola* are very poisonous), or from cuttings taken in the autumn when mature, and struck under bell-glasses, in a temperature of 50°, placing those that have formed a callus into greater warmth in the spring, to foster the production of roots. The stocks thus raised may be used after they have been grown for one year in pots. Seedlings will scarcely be fit to make stocks before the third year. Grafting should be performed with ripe wood, low down on the stocks, in either spring or early autumn, using grafting-wax to cover the point of union, the grafted stocks being kept in a close case in a temperature of 55° to 58°.

FARM-YARD MANURE: Ignoramus. The creatures seen in the dung are a false wireworm or millipede—*Julus guttatus*, which do not feed on living tissues, but on what is decaying. They will do no harm but rather good, as the myriad bodies in decaying, furnish additional plant food. The manure itself should be stored in a shed, and thus be made drier than the sample sent, so that it may be crumbled or sifted the more readily to mix with the soil.

MANURE, HOME-MADE: Ignoramus. The wood-ashes will afford potash, the pigeon's dung is rich in nitrogen, but it is apt to injure the

unless present in small proportion; the bones should not be burnt, as that turns them into bone-ash, an almost valueless article as plant-food. You should boil the bones till the grease is removed, and no longer. They then may be crushed or milled, or disintegrated by pouring sulphuric acid upon them, or leached in a tub by putting bones and wood-ashes in alternate layers, and leaving it exposed to the weather. You would find the Moule "Earth-closet" a valuable adjunct to the garden, also house-slops, soap-suds, fowls and pig-dung, &c. Soot is a better manure than charcoal, containing as it does a good deal of ammonia. For pot-plants, horse and sheep's-dung soaked in water, hanging a bagful of fresh soot in the tank or tub, makes a capital liquid-manure.

MARKET GARDENERS' COMPENSATION ACT, 1895: R. H. A copy of this Act can be purchased at Messrs. Eyre & Spottiswoode, Queen's Printers, East Harding Street, London, E.C.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—*W. T. N. Yorks.* It is impossible to do anything but guess at the names of some of the things you send, the specimens being only imperfect scraps. 1, may be *Strobilanthes Dyerianus*, but the colour has dried out; 2, *Adiantum Farleyense*; 3, *Gymnogramma ochracea*; 4, *Asparagus plumosus*; 5, too small—send in flower, or mature specimen; 6, a scrap of *Polypodium aureum*, probably.—*F. Arnold Lees.* *Canaigre* is the produce of *Rumex hymenosepalus*. It is used in tanning leather.—*Anslie.* 1, *Cupressus (Retinospora) pisifera*; 2, *Juniperus chinensis*; 3, *Cryptomeria japonica*; 4, *Cupressus torulosa* var. *majestica*; 5, *Libocedrus decurrens*; 6, *Juniperus Virginiana* var.; 7, the true *Thuya plicata*, commonly called *Lobbi*, or *gigantea*; 8, *Pinus*, next week; send cone, if possible.—*C. J. R.* The flower of *Cattleya Trianae Williamsii* is of a very fine variety indeed.—*W. S.* 1, *Brassavola Perrini*; 2, *Odonoglossum pulchellum*; 3, *Adiantum reniforme*.—*J. P. K.* 1, *Miltonia Russelliana*; 2, *Epidendrum virens*.—*G. T. R.* The Fern is *Scolopendrium vulgare crispum*; the other plant *Statice profusa*.—*W. D.* 1, *Polygala Dalmatensis*; 2, *Salvia coccinea*; 3, *Echeveria retusa*; 4, *Lastrea Standishi*; 5, *Anthericum lineare variegatum*; 6, *Davallia platyphylla*.—*A. B. Newbury.* 1, *Ligustrum lucidum*; 2, *Picea nigra*, probably; 3, *Tsuga canadensis*; 4, *Cupressus Lawsoniana*; 5, *Thuya orientalis* variety; 6, *Pinus excelsa*.—*C. B.* *Cypripedium insigne*.—*Ignoramus.* *Cypripedium insigne*.—*D. W.* *Thuya dolabrata* var. *late-virens*.—*J. W.* 1, *Scilla bifolia*; 2, *Heuchera*, we cannot tell the species; 3, *Ruscus aculeatus*; 4, *Begonia echinosepala*; 5, *Selaginella Martensii*; 6, *Rhododendron dauricum*.—*C. B.* Materials insufficient.

ORCHIDS ON THE BORDERLAND OF BURMA AND CHINA. C. Luxton. *Anthogonium*, 1 sp.; *Acampe*, *Cypripedium*, several sps.; *Ornithochilus*, *Phalaenopsis*, *Trichosma*, *Thelasis*, *Tainia*, *Uncifera*, *Sunipia*, and *Dendrobium*. See Hooker's *Flora of British India*, the vol. referring to Orchids.

PANCRATIUMS: C. B. W. & Co. The one generally grown is *P. fragrans*, the correct name for which is *Hymenocallis ovata*. The bulbs should be potted singly into 6 or 7-inch pots, according to their size, or several together in larger pots. A compost of half loam and half leaf-soil, with the addition of a fair amount of silver-sand, will suit them, but if convenient, it is better to substitute peat for one-half of the leaf-soil. The plants will remain perfectly healthy, and flower profusely in the same pots for several seasons, providing they are given supplies of liquid or chemical manure. In fact, it is a great mistake to frequently move them. Give plenty of water, heat, and feeding when the plants are growing; but less of either will suffice afterwards. This species is a stove plant, and may be easily propagated by means of offsets, or by seeds.

RENT-PAYER PEA: J. M. In reference to the enquiry inserted in last week's issue of the *Gardeners' Chronicle*, Mr. R. G. Mechie, gr., Beechwood, Fallowfield, writes, that the variety was sent out by Mr. H. Brownhall, nurseryman, Sale, Manchester.

TENNIS COURT: A. R. A tennis court for a three or four-handed game should be 78 feet long and 36 wide. First draw this oblong right-angled figure. Then 4½ feet within the side lines draw two "service" side lines 42 feet long, and connect the ends with two other lines, which will be 27 feet long. Then divide equally the length and breadth of the inner square with two other lines.

THE ZERO OR 0 POINT ON THE THERMOMETER: A. F. The 0 on the absurd Fahrenheit thermometer is 32° below the point at which water freezes at the sea-level. In the Réaumur and Centigrade scales the 0 point is, on the contrary, the freezing-point of water, warmth being recognised by degrees above and cold by degrees below 0; hence it is easy to know by affixing the plus +, or minus — sign to a degree what is meant—for example, + 12 on the Réaumur, or + 15 on the Centigrade scale are equal to 59° on the Fahrenheit scale. The Fahrenheit zero, or 0, = on a Réaumur scale — 14°, and on a Centigrade — 18°. The only advantage that the Fahrenheit thermometer has to offer is the small divisions of the scale, which for garden purposes are of no practical use. It should be replaced gradually by the sensible centigrade!

TULIP CHRYSOLORA WITH AN UNUSUAL NUMBER OF FLOWERS: D. Chaplin. The reasons for the fasciation of two flower-shafts that spring from the parent bulb, and the flowering of the offset which in the usual course would not have produced a flower till next year, are uncertain. It is probably due to extra vigour imparted by very favourable conditions during the formation of the bloom last year, helped by similar conditions this season. The leaves show no evidence, however, of this.

TULIPS FAILING TO FLOWER FREELY: R. A. There appears to be something in your soil detrimental to the roots, as part of these are decayed, and the rest weak. The fact that the bulbs are sound and good also points to the failure being due to some detail in the cultivation that we are unable to specify.

VIOLETS FAILING: A. B. The plant sent is evidently considerably more than one year old, and therefore unsuitable for early frame work. We remark the coarse strong runners, made last year, which should not have been allowed to develop, are still on the plant. You do not say so, but it seems to us that you are trying to obtain flowers from aged plants lifted in the autumn, which, unlike young ones raised from off-sets taken last April, resent disturbance late in the year. A properly prepared plant grown in a half shady spot in good soil, and kept quite free from runners will lift in September or early October with the root-mass intact, and will scarcely feel removal. Whereas old plants, owing to the much wider ramification of their roots, can scarcely be removed without feeling the operation.

WEIGHT OF A CROP OF TOMATOS: C. B. W. If a plant under glass be kept to one stem it may, if early planted, carry during the summer months from 12 to 15 lb. of fruit. We have had plants trained fan-shaped on a south wall outside which produced thrice that weight. Too much importance is given to the one-stemmed fashion of growing the plants. It may in a general way suit plants grown in smallish pots or out in the open quarter; but against warm walls and on trellises under glass fuller development of the branches and less mutilation of the plants, seems to be the better practice.

WHAT FOLLOWS A FOREST FIRE IN CANADA AND U.S.A.: Mac. The reason that hard-wood trees come up on land previously covered with coniferous trees may be due to the fact that such wood act as traps to the seeds that are capable of being transported by the wind (winged seeds), which falling to the ground among the firs, germinate in numerous instances, but, owing to the dense shade seldom make trees. The destruction of the fir by fire gives the seed and the seedlings that escape destruction a chance of germinating and growing. Of course, a seedling hard-wood tree, not destroyed down to the root, would spring up again, and perhaps with renewed vigour, as witness the familiar example of cutting-back seedling Apple and Pear stocks in a nursery. The heat arising from a forest fire acting on the seeds laying in moist leaf-mould, may, moreover, exercise a stimulating effect on seeds that, although not freshly fallen, retain their vitality. We know that old seed will vegetate under favourable conditions of heat and moisture which without this stimulation, would fail to germinate.

THE

Gardeners' Chronicle.

SATURDAY, FEBRUARY 26, 1898.

WALMER CASTLE.

THERE are few finer views to be had along the range of the Kentish coast than those afforded during a ramble through the policies of Walmer Castle and its delightful surroundings. The site whereon the castle stands is sheltered on all sides save the front, which faces the sea and the French coast, by thickly studded trees. It is only separated from the seashore by a natural bulwark of shingle and a belt of roadway. The sea and landscape from here are both glorious. When the winds blow high, as they so often do, and the sea is consequently rough, one may at such times count a hundred ships or more anchored in the Downs. In a few hours, early next morning say, look again and they have all vanished, gone on their several interrupted ways. Enough, however, has been written by others of this prospect, and the castle too; our present purpose is with the gardens mainly, for of these we had often heard favourable mention made—so taking advantage of a short stay last autumn at St. Margaret's Bay, itself a lovely spot, we walked over thence along the cliffs, and through Kingsdown, to see for ourselves. The castle comes suddenly into view on reaching the asphalted parade in front, for it is completely hidden from view by the surrounding, until one does so; then it affords what has aptly been termed the brightest piece of landscape in England within an equal distance of the sea. At night, by the light of the moon, no enchanted castle certainly could look more dream-like and romantic.

Turning into an avenue from the roadway, we soon arrive at the garden entrance, near the castle porch. Ringing the bell at this gateway, the reverberation of which startlingly breaks the stillness reigning around, we pass through from the outer world into the first garden, the appearance of which, to our thinking, is singularly suggestive of one belonging to an old monastery or convent of times long gone by. The walls are high, and on the far side there is a thickly-trellised arbour running its length, which one might be excused for taking for cloisters. Indeed, surprise would hardly have been excited had a portly monk of the middle ages advanced to act as guide instead of the smart young gardener who came smilingly forward. This garden teems with all the conventional flowers which find a place in floral calendars, but their enumeration would hardly be of interest, as there is nothing of a very rare kind. The walls showed goodly crops of fine Marie Louise Pears, as did also the espalier-trained trees bordering the pallisade of Apples. The arbours were covered with Roses, and here Gloire de Dijon struggles for supremacy with Maréchal Niel, and the blushing La France, the effect in the season being particularly fine, the last-named attaining to an extreme perfection. This garden

is hardly an acre in extent, but it is only one of several, and we proceed on our way across a grassy plot whereon stands a large Tulip-tree (*Liriodendron tulipifera*) planted by William Pitt when Lord Warden. This tree is covered in most summers with its yellow Tulip-like flowers. Mr. Pitt also planted in the grounds a row of Sycamore and Lime-trees. This spot is of historic interest as being the place where, in the company of Lord Nelson, those grand naval operations were planned and thought out by the two, which resulted in such brilliant successes. In the far corner of the garden we are entering stands the Weeping Willow, an off-shoot of the one which overshadows the great Napoleon's tomb at St. Helena, planted here, in memoriam, by his conqueror, Arthur, Duke of Wellington. From its situation the sun's rays do not often illumine the spot, which has been well chosen for such a memento. When the Duke was Lord Warden, he made great alterations both at the castle and in the grounds, converting what had hitherto been but a gloomy fortress into a comfortable and habitable dwelling. Of course, we have all heard of his plain little bedroom here, like the one at Apsley House, with its simple iron bedstead and hard mattress, fitted only for a warrior; and also his favourite walk on the ramparts, where he was to be seen every morning early. The rooms at Walmer are all small, and royalty, or any great house-party, could not be conveniently entertained there. The Duke has left other evidences of his tenancy in the shape of trees planted by him—Figs and others—in various parts.

We soon arrive at the broad walk, as it is appropriately termed, and this is evidently, in the opinion of our guide, the *pièce de résistance* of his domain, for he dwells proudly on its description. It runs from the base of the steps descending from the terrace for about a hundred yards, leading to the large lawn for tennis or croquet, out into the park grounds. From this walk, as well as from the terrace above, a lovely sylvan view, ending in a picturesque glade, is obtainable. Deep flower-beds run the entire length on each side, bounded by high-trimmed Myrtle hedges. It is pleasing to hear that Lord Salisbury is very fond of flowers, and that many of the gardening operations are directed by the Marchioness herself. The arrangement of this walk is entirely her conception, and she prefers, as is seen, the old or variegated style of growing in preference to that adopted by many of the horticultural experts of the present day—the growing in masses of the same plant. Passing on, we get a glimpse at the bed of the moat, which is partly utilised as a kitchen garden, the portion in front forming a large Strawberry-bed—the fruit comes to hand early here, the spot being very sheltered. Then we see the vinery, the Tomato-houses, and a small fernery; another garden, on the opposite side, similar to the first, and our inspection draws to a close. There is a tall Acacia-tree standing here, the top of the trunk of which is withered, as if struck by lightning, which was planted by Queen Elizabeth when she came to visit her father's castles; and Henry VIII. himself planted near by a Fig-tree, which is still in full vigour, and bears heavy crops. He built Walmer, Deal, and Sandown among other castles, and skilfully fortified posts on the Kentish coast in the early years of his reign, when, with his fleets and his armies, he proved such a powerful foe to Francis I., his royal cousin, and the French nation. Great is the pity that so highly endowed and gallant a monarch should

in later life degenerate so as to be remembered for the evil he committed rather than by the grand work he did. The erection of these castles alone and their fortification are recording monuments of military genius. Pondering on many events which the mention of his name brings to mind, we take our leave, thanking the young gardener, Mr. Dales, for his civility and information. Emerging from the precincts, Walmer village and church are discernible through the trees nestling on an eminence in the rear. There is a number of fine mansions dotting the country around. One can easily fancy it a fitting neighbourhood for retired military and naval heroes, who, we understand, form many of its inhabitants. The morning is beautifully clear, and it is with some surprise we hear a fog-horn sounding from out at sea. A large liner is passing in the offing, and it seems a director of the company to which it belongs resides in one of the mansions just alluded to. The siren of this vessel is sounding him a salute in passing, which it appears the ships of that company always do. A squad of the red Marines is being drilled in front of the Castle, and a number of the Marine Artillery are practising the bugle-calls and the drum-beats down on the beach. A couple of young artists, foreigners apparently, are sketching the Castle and landscape, exciting the interest of the passers-by, who stop and critically look on. We sit down on a bench near by to indite these hasty notes, but happily are left alone to indulge in meditation fancy free by the sea waves. *Norman Brown.*

NEW OR NOTEWORTHY PLANTS.

DEUTZIA CORYMBIFLORA.

THIS new shrub, found in Ise-Tchuen (China), by the Abbé Farges, and introduced into France by M. Maurice de Vilmorin, is a plant with rather slender branches; the year's stems erect, round, with a lenticellate bark, rather long internodes, leaves large, almost sessile or with a petiole not more than half a centimètre long, oboval-lanceolate, pointed, very finely dentate, wrinkled on both surfaces, with very short hairs above, the upper surface dark green, the lower clear green. The stems of the preceding year bear in all the axils composite almost corymbiform panicles, each including from fifteen to forty flowers. The pedicels are very short and very slender, the calyx cup-shaped, clear green, with five small dark green teeth. The five petals, well open, wide below, pointed at the extremity, are completely expanded. The stamens, five large and five small, have very large-winged filaments on which the clear yellow anther is directly inserted; the three styles are very short, as long as the small stamens, and hidden by them. The filaments of the stamens form a close and firm column, remaining so till blooming is over. The appearance of the flowers somewhat suggest those of *Solanum jasminoides*. The usual blooming season is the first fortnight in June, the shrub is then covered with a profusion of small, snow-white blossoms; the stems of the year often put forth fresh blooms in August and September. *V. Lemoine, Nancy.*

ORCHID NOTES AND GLEANINGS.

ONCIDIUM SPILOPTERUM (SAINTLEGERIANUM)

THIS handsome species, of which re-introduction has been made of late, proves to be one of the most useful of the tolerably cool-house *Oncidiiums*, and an easy plant to cultivate. A good variety of it has flowers equal to those of *O. varicosum*, and quite as showy. A number of specimens of it are flowering out of an importation made by Messrs. W. L. Lewis & Co., of Southgate, and while all are pretty, there is

variation both in size and colour. The sepals and petals are of a more or less dark tint of red-purple; the front lobe of the lip, bright chrome-yellow; the conspicuous crest, claret-purple; the side lobes often yellow, the whole flower presenting a striking combination of colour. A grand variety of it is also sent by Messrs. Linden, l'Horticulture Internationale Brussels. *J. O'B.*

LÆLIA ANCEPS SCHRÖDERIANA.

This is one of the most beautiful of the white forms of *Lælia anceps*, of which there appear to be several classes, according to the localities in which they were collected. The main difference consists in the section to which *L. a. Schröderiana* belongs, having broader sepals and petals than the ordinary type, and in the labellum having a larger and more openly displayed front lobe, which causes the parts of the flower to arrange with each other better.

A good example is sent from Tyn-y-Coed, Weston-super-Mare, by W. M. Appleton, Esq., who considers it the best of his white *L. anceps*. *J. O'B.*

LYCASTE FULVESCENS.

This very distinct species, discovered by Linden about 1842, at some 6000 feet elevation on the Cordilleras of New Grenada, is notable for its singular-looking, drooping flowers, although it cannot lay claim to be showy like some of the genus. The scapes are about 6 inches long, and freely produced. The sepals and petals are of a light brown colour, the colour in the petals merging into white as it approaches the column, which is white. The lip is narrow, and fimbriated at the edges. In general appearance, this plant resembles *Lycaste Skinneri* when out of flower, the bulbs being, however, slightly narrower, as also the leaves. *R. L. Harrow, Royal Botanic Garden, Edinburgh.*

THE CULTIVATED SPECIES OF ASPARAGUS.

The genus *Asparagus* has grown in horticultural favour since the discovery of that most useful species *A. plumosus*. There are now two dozen species in cultivation at Kew, and there are also several others in Continental collections which we have not yet succeeded in obtaining. The decorative value of most of these is such as to justify a somewhat lengthy descriptive notice of them. The descriptions are necessary to enable growers to distinguish the several species which are more or less "mixed" in some collections. They are taken chiefly from the plants grown at Kew; but I have also consulted the monograph of the genus by Mr. Baker in the *Journal of the Linnean Society*, xiv. (1874), and his recent monograph of the South African species, published in vol. vi. of the *Flora Capensis*.

The genus comprises about 100 species, and these are spread through the temperate and tropical regions of the Old World. There are forty-eight species in South Africa alone, and it is from this region that the most ornamental of the greenhouse species have been obtained.

All the species are perennial, with generally fleshy roots or tubers. The stems are annual in some, perennial in others, most of them being spiny climbing shrubs growing to a length of from 5 to 20, or even 50 feet (*A. falcatus*). The true leaves are usually changed into spines, which are situated at the base of the branches, and are often stout and woody. The false leaves, termed cladodia, are the linear or hair-like organs, which we popularly call leaves; they are in reality modified branches. I have, however, used the terms leaves and spines in their popular sense in the following descriptions.

These cladodia are nearly always arranged in clusters at intervals along the branches, and the flowers generally spring from their axils. *A. medeoloides* is an exception, the cladodia in that species being solitary and leaf-like. They usually fall off the hardy species in winter, and they are easily affected by unfavourable conditions in all the species. Most of them flower and fruit freely under cultivation, so that seeds are available for propagation.

CULTIVATION.

All the species described below require greenhouse treatment, unless otherwise stated. Although found usually under dry, arid conditions, they are most satisfactory under cultivation when treated liberally in regard to soil and moisture. I have seen magni-

forms of *A. plumosus* except *nanus* strike root freely. I have tried to root *A. falcatus*, and failed; but they can all be propagated by division of the root-stock. When pot or basket specimens get shabby, it is a good plan to keep them dry for a few weeks, and then shake them out, repot in good soil, and start in a little

FIG. 46.—*ASPARAGUS LARICINUS*. (SEE P. 123.)

ficient specimens of *A. plumosus nanus*, *A. Sprengeri*, and *A. crispus* grown in a few months from small plants when potted in rich soil and placed in a hot, moist stove. Many of them are specially valuable for draping pillars, rafters, &c., in positions which are too shaded or damp for ordinary climbers. The majority of the species may be grown as basket plants. Cuttings formed of the small branches of all the

extra warmth. I am indebted for specimens and information to the Curators of the Botanic Gardens of Cambridge, Edinburgh, and Glasnevin, and to Messrs. F. Sander & Co.

A. acutifolius.—An old garden plant which we owe to South Europe, and which is hardy here. It has a fleshy rootstock, hard, wiry, brown stems about 5 feet high, with rigid branches 3 to 6 inches long, thickly

clothed with tufts of grey-green, hair-like, rigid leaves, which, in exposed situations, are almost spinous. Flowers yellow, a quarter of an inch in diameter. Berry pea-like, coloured deep crimson. This is cultivated in continental gardens under a variety of names, and is, perhaps, the best known of the hardier species. It is killed down to the ground in winter, but it starts into vigorous growth again in April or May. I have a specimen from Mr. Lynch, of Cambridge, which he collected at Costabelle, near Hyères.

A. æthiopicus.—An old garden plant, often called falcatus. It has been cultivated many years

A. africanus.—A vigorous climber, of which there is an old example in the Succulent-house at Kew, which produces annually numerous woody stems $\frac{1}{2}$ inch in diameter, and 12 feet long, smooth, pale brown, clothed with stout spines $\frac{3}{4}$ inch long, and an inch apart. These spring from a root-stock composed of a mass of ovoid fleshy tubers, 3 inches long. The leaves are borne on slender branches about 6 inches long, and they are rigid, dark green, $\frac{1}{2}$ inch long, densely clustered and persistent. The small white star-shaped flowers are produced in axillary umbels, and they are succeeded by globose berries $\frac{1}{4}$ inch in

the species is very variable. It was cultivated by Philip Miller. I can recommend it as a useful climber for large greenhouses. A native of the tropics of Asia and Africa, as well as the Cape.

A. Cooperi.—An elegant plant in the way of *A. plumosus*, and for which we are indebted to Mr. T. Cooper, who collected it in South Africa for Mr. Wilson Saunders, in whose garden it flowered in 1874, when it was described by Mr. Baker in the *Gardeners' Chronicle*, vol. xxi. p. 818. It climbs to a height of 10 feet, and has crowds of slender branches, with a slender spine at each joint, and which branch again, forming a kind of frond clothed with fine hair-like leaves $\frac{1}{2}$ inch long, in tufts of about a dozen. Flowers creamy-white, very small. Berry, the size of a pea, red. (Mr. Baker says stems 1 to 2 inches thick, but I have not seen any that exceeded $\frac{1}{2}$ inch). We have a plant which is apparently the same thing, from Messrs. F. Sander & Co., who imported it from South Africa.

A. crispus.—A popular garden plant, generally known as *A. decumbens*. It was in cultivation a hundred years ago, and has been in the Kew collection for at least the last twenty-five years. It is usually grown in baskets suspended near the roof, its long, hair-like flexuose stems and branches forming a cloud-like tangle, which clothed with dark green leaves and white star-like flowers with orange-coloured anthers have a pretty effect. The root-stock is composed of numerous fleshy, oblong tubers. The stems are annual, 2 to 4 feet long, freely branched, the branches zig-zag, and bearing numerous glaucous green leaves arranged usually in pairs close together, and not more than $\frac{1}{4}$ inch long. This species is remarkable in having an oval soft berry $\frac{1}{2}$ inch long, containing about half-a-dozen seeds. The berry is brown when quite ripe. The seeds germinate freely. A native of South Africa. I have seen plants of it named *A. stipulaceus*, but the true plant of that name is very different.

A. declinatus.—A plant of this was received without name from Grahamstown, in 1892. Messrs. Sander & Co. have also imported it from Natal. It is allied to *A. plumosus*, from which it differs in having deltoid prickles, pale green stems, and smaller berries. The stems on the Kew plant are 2 feet long, erect, wiry, with hair-like drooping branches bearing numerous tufts of bright green thread-like leaves $\frac{1}{2}$ inch long. Flowers very small, white, campanulate. Berry, small, globose, one-seeded. According to Miller this species was in cultivation here a century ago. There is also at Kew a plant with thin wiry stems, less than a foot high, which is probably a small form of *A. declinatus*. Both this and the type lose most of their leaves in winter.

A. falcatus (fig. 47).—One of the most striking plants in the large Temperate-house at Kew is an enormous specimen of this *Asparagus*, which is trained against the north staircase, where it has formed a perfect thicket two yards through and 25 feet high, of long rope-like intertwining spinous, fawn-coloured stems, some of them fully 50 feet long, and clothed with wiry woody branches, bearing whorls of leaves from 2 to 3 inches long, nearly $\frac{1}{4}$ inch wide, falcate and bright green. The stems when young are thick, and succulent as the best examples of the *Asparagus* of the kitchen garden, and they are grey-green mottled with brown. In 1872, Mr. Baker described this identical plant in the *Gardeners' Chronicle* under the name of *A. æthiopicus ternifolius*. It then attracted much attention, "the stems being crowded from top to base with graceful firm sword-shaped spreading bright green leaves, and copious clusters of bright star-shaped pure white flowers with red anthers. It is one of several species brought from South Africa by Mr. T. Cooper." For large conservatories, and particularly in moist shady corners where ordinary climbers will not thrive, this is an ideal plant. It is a native of the tropics of Asia and Africa as well as the Cape.

A. laricinus (see fig. 46).—This handsome species has been in the Kew collection at least twenty years. It is grown in the Succulent-house, where, from a vigorous root-system, it sends up annually stout succulent shoots, which grow to a length of about 12 feet, and when fully developed are decidedly orna-

FIG. 47.—*ASPARAGUS FALCATUS*.

at Kew, where, in the Succulent-house, it has formed a dense mass of fleshy tubers, from which spring numerous green wiry stems, 10 feet long, $\frac{1}{2}$ -inch in diameter, bearing brown sharp spines $\frac{1}{4}$ -inch long, and flat falcate leaves $\frac{1}{2}$ -inch long, occurring in clusters of from three to six upon the branches. Flowers white, in racemes 3 inches long. Berry globose, $\frac{1}{2}$ -inch diameter, one seeded. A useful climber for the warm conservatory, not unlike the popular *A. Sprengeri* in appearance, and superior to that species in being evergreen under ordinary treatment. The variety, *natalensis*, also grown at Kew, has larger leaves. The species is wild in south and tropical Africa.

diameter, and one-seeded. This species appears to be very common in South Africa. Mr. Baker describes four varieties of it.

A. asiaticus.—A vigorous climber, the Kew plant having stems 30 feet long, $\frac{1}{2}$ inch thick, wiry, bearing stout spines below, and long slender drooping branches above, clothed with very dark green hair-like leaves $\frac{1}{2}$ inch long, soft and velvety to the touch. It grows well in a somewhat shaded position, pushing up stout shoots every year, which attain their full length in a few weeks. Flowers few, axillary, small, white. Berry globose, one-sixth inch in diameter, one seeded. This description does not agree with that given by Mr. Baker, but judging from wild specimens

mental. It is similar to *A. retrofractus*, differing in its stouter stems, larger prickles, and longer leaves. The stems are perennial, terete, dark brown, woody, $\frac{1}{2}$ -inch in diameter at the base, very spinous, freely branched, the branches zig zag and grey, the leaves in clusters $\frac{1}{2}$ inch apart, hair-like, $1\frac{1}{2}$ inch long, bright green, persistent. Flowers axillary, many in a cluster, small, campanulate, white. Berry globose, dull red, one-seeded, one-sixth of an inch in diameter. Common in various parts of South Africa. I cannot find when it was introduced, and I have never seen it in cultivation elsewhere. It is an excellent pillar-plant. *W. Watson, Kew.*

(To be continued.)

LÆLIA ANCEPS WADDONIENSIS.

OUR illustration (fig. 48), represents the fine form of *Lælia anceps*, which was exhibited by Philip Crowley, Esq., Waddon House, Croydon (gr., Mr. J. Harris), at the Royal Horticultural Society, on February 8 this year, when it was awarded a First-class Certificate. *Lælia anceps Waddoniensis* belongs to the *L. a. Schroderiana* class; its flowers are pure white, the side-lobes of the lip bearing clear light purple lines.

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Strawberries.—The old and new plantations of Strawberries should now be thoroughly cleaned, all decaying leaves being removed by cutting them off close to the plant with a knife, and the beds hoed over to eradicate weeds, all runners that may have grown since the beds were cleaned in the autumn being removed, and only the original plants left. Some gardeners allow some of the runners to remain each year with a view of replenishing the bed; it, however, is much better to make a new plantation with prepared runners whenever an old bed shows signs of giving out, and, as a general rule, it may be said that a plantation is of small value after three crops of fruit have been taken. The proper time for planting a bed is early in the month of August. A Strawberry bed or plantation should not be dug over after it is planted, the chief roots being near the surface, and these would be destroyed or much injured by digging the land. If farmyard manure was applied as a top-dressing it should now be pulverised with the rake, so as to be readily incorporated with the soil. Mineral manures are of great assistance to Strawberries, and they are easy of application without any disturbance of the roots; and a liberal dressing may be put on exhausted beds just previous to the commencement of growth. Potash and soda should form the chief ingredients, the Strawberry being rich in these substances, therefore wood-ashes obtained from green twigs and branches form a good application. Whatever is given must be scattered evenly among the plants, and stirred in with a Dutch-hoe. Where the Grove End Scarlet is still grown for preserving purposes, and the Hautbois for dessert, a method differing from the above should be pursued, for, owing to the excessive growth of the runners of these varieties it is not possible or desirable to keep the beds clear of them, and for convenience of gathering and cleaning, and as a means of securing plenty of fruits, it is better to let each row extend to a width of $1\frac{1}{2}$ to 2 feet, and have alleys $1\frac{1}{2}$ feet between. The first-mentioned variety, once very common in gardens, is seldom met with, yet it is valuable on account of its small size and bright colour when boiled, being equally good whole or as a jam, and it is a great cropper. The varieties of Hautbois are favourites with many on account of their peculiar and agreeable flavour. It is very necessary to obtain the plants from a good bearing plantation, there being male and female plants. Vicomtesse H. de Thury gives a better crop for preserving than Grove End Scarlet, and is rather larger.

Alpine Varieties are very useful for autumn fruiting, and are much esteemed for their refined flavour by many persons. Some are grown from runners, and one variety can only be increased by means of seed, no runners being made. All the varieties can be raised from seed, and the Improved Red should be sown in heat now, and if the plants are grown on quickly before planting out in April, they will afford fruit in the autumn. Runners of those varieties that make them may also be planted

in rows of mixed white and red varieties 2 feet apart, and 9 inches between the plants, in a moist situation. The land should be heavily manured previous to bastard-trenching it. In planting, make the soil very firm about the roots, and occasionally in dry weather apply water at the root. It is well to slightly mulch the land after planting, and afford a rich mulch before the fruit shows, with an occasional hoeing, which is all the attention a bed of Alpines requires to keep it in good condition for several years. It is, however, good policy to plant a few hundreds of young plants, either seedlings or runners, each year, destroying a corresponding number of the oldest plants.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Ericas.—The staking and tying of the plants should now be completed, no more stakes being employed than are actually required, care being taken to remove the whole of the decayed ends of stakes, so that none is left in the soil, or fungus may spread and destroy the roots. If possible, place the new stakes in the holes from which the old ones have been withdrawn, and use stout green thread as the tying material. Young *Ericas* should not be allowed to become pot-bound. The plants do best in lumpy fibrous peat of good quality, that has been stacked not less than twelve months, a small portion of charcoal of hazel-nut size, and clean washed coarse silver sand; and the pots should be clean, and the drainage carefully arranged, big crocks at the bottom and finer ones above. Do not disturb the ball further than to remove the drainage, and pot firmly, working the compost down the side of the ball. Let the plants stand on a cool bottom, and where they can receive plenty of ventilation, merely preventing the entrance of frost. In the case of repotted plants, do not afford water to them for some days after potting, but syringe the outsides of the pots, for the longer the plants can be kept without applying water to the soil after repotting the better it will be for them.

Epacris.—Those plants which flowered early should have the main shoots cut back one-half their length, and very thin shoots removed. Afterwards place them in a cool position, where they can have abundance of air, and be syringed once or twice daily, repotting those that require it as soon as growth recommences. A similar kind of compost should be used as that advised for *Ericas*, and the same care should be exercised in potting them. Any plants that did not start freely into growth last season may have the flowers picked off, and be allowed to grow without being cut back.

Pancratiums.—Plants that have rested for some months may now be repotted or top-dressed, as the case may demand. If the latter, use two-thirds loam, and one-third of dried cow-manure, passed through a moderately fine-meshed sieve; if the former, use a mixture of good fibrous loam in a lumpy state, some charcoal broken into small lumps, cow-manure, and sand. In repotting, shake away all of the old soil from the roots, and be careful in planting not to bury the bulbs, and to spread out the roots near the surface. These plants succeed in almost any position in the stove after potting until re-established, if syringed freely, but not afforded much water. If introduced into heat, the plants will come in useful for early decoration.

The Forcing-pit.—*Spiræa japonica*, *S. confusa*, *Staphylea colchica*, *Lily of the Valley*, *Deutzia gracilis*, and *Lilium longiflorum Harrisii* just showing the flower-buds, will force readily if strict attention be paid to affording water. In the case of the *Lily*, it is a good plan to place the pots in larger ones, and fill in round them with moss or Cocoa-nut fibre refuse, in order to hinder evaporation of moisture from the soil, and maintain an equable degree of warmth and moisture in the soil. Bulbs will come on quite quickly enough in cool pits during the present mild weather, and the flowers will in consequence be finer and last much longer than those grown in heat. Examine plants of *Marguerites* for signs of the maggots in the leaf, and destroy them before their numbers increase. Badly-disfigured leaves should be removed and burnt. Lift and place in pots and boxes a batch of roots of *Solomon's Seal*, and grow in gentle heat for a time, and then gradually harden off; the flowers are useful for cutting, &c.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

Potatos.—It is now time to plant tubers of some early variety at the foot of the south walls, or on the border in front of such wall. Not much manure should be used at planting-time, and I prefer to

apply instead wood-ashes, charred earth, ^{over} Cucumber or Melon-bed soil. It is well to plant beds of 5 feet wide if away from the wall, and in case of need to span these with bows of Hazel, &c. support mats, canvas, &c.

Parsley.—Seeds of *Myatt's garnishing*, triple-curl or Fern-leaved Parsley, may now be sown on a border in rows 1 foot apart, covering the seed with finely-sifted soil to the depth of $\frac{1}{2}$ inch. The old lines of Parsley should be cleared of dead leaves, and a slight sprinkling of wood-ashes applied between the rows, and mixed with the soil by using the hoe. During severe frost, protection should be afforded the plants in the manner described in a former calendar.

Turnips.—A sowing of Turnip-seed may be made on a warm border, choosing quick varieties, as *Early Milan*, or *Snowball*; protect the seeds from birds by netting supported on forked twigs.

Planting Crowns and Sowing Seed of Asparagus.—It will usually be found necessary to trench the land intended to be formed into beds to the full depth the soil will allow without spoiling it, putting plenty of half-rotten manure at the bottom of the trenches, and some fully decayed beneath the uppermost spit; some half-inch bones may likewise be added and mixed with the upper spits. Leave the surface in a rough state till the time comes for sowing and planting. The latter should not take place till the stems have grown a few inches, as by doing this there is little or no risk of decay setting in on any part that is broken or injured. Before proceeding to plant, afford the soil a good dressing of road-grit, sand, or lime-rubbish, forking these ingredients into the land by nearly one sp it deep. The plants should be strong one-year or not more than two-year-old seedlings, and these should be set out in rows 15 inches apart, and 12 inches between the plants. A cloudy day, when rain seems imminent, should be chosen for lifting and planting, and much care must be taken to expose them for as short a time as possible to the air. Excellent results are obtained by sowing seed early in the month of March, in beds of three rows each, or in single lines on the flat, and not transplanting but thinning them. The drills should be drawn at 15 inches apart, and have a depth of 1 inch; and to better ensure germination, cover with finely-sifted soil taken from the alleys or from the surface, using a rake to finish off and level the soil. The alleys between beds should not be less than 2 feet. Good varieties are *Early French Giant*, *Battersea*, *Conover's Colossal*, and *Reading Giant*.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Pine-apples.—These fruits are now imported into this country to such an extent, and sold at such low prices, that home-grown Pine-apples cannot compete with them, if appearance alone be thought of. It is in point of flavour that the home-grown fruit is still the best flavoured and ripest. The coming month is a time when a good deal requires to be done in the pinery, in the renewing of spent hot-bed or plunging material, and in repotting. Bottom-heat is obtained in a variety of ways, from hot-water pipes, from tanner's bark, and from the leaves of the Oak and the Beech, which latter are perhaps the best of all. Whether for partial or entire renewal, the necessary quantity of tan and of tree-leaves require to be got in readiness, by placing in a heap to ferment. The walls of the pit or house should be lime washed, and the wood-work and glass cleaned with soap and water, and the men set to clean the plants if scale affect them. Let the new leaves be trodden firmly, and enough of them put in to allow for considerable shrinking in bulk. Usually the bottom-heat is derived from hot-water pipes, or from a tank under the bed, or from a bed of tan $2\frac{1}{2}$ to 3 feet thick. If tan be used for affording bottom-heat, and not merely to plunge the pots in, only sufficient new material will be required as will supply the necessary degree of bottom-heat for six months; if, however, there are hot-water pipes, or a hot-water tank, these methods of heating may remain out of use so long as the tan keeps its proper degree of heat. The old tan that is not decayed generally should be passed through a $\frac{1}{2}$ -inch meshed screen or sieve, in order to free it of the finer particles, the coarser being kept back for mixing with the new tan. The proportion of new to old tan may range from $\frac{1}{2}$ to $\frac{3}{4}$, and both should be mixed well together. The Pine-apple will throw good fruits when grown in loam, horse-dung, and leaf-soil; in loam and peat, or in loam alone if it be of good quality, and in rich peat. A kind of soil available by most gardeners in country places, is light pasture-loam of which the fibry parts are partly decayed—that is, it should

have been cut in the autumn, 2 to 3 inches thick, and stacked in an open shed. These turves should be pulled to pieces by hand, large or small as may suit the plants for which it will be used, i.e., about the size of a hen's egg for a plant to be transferred from an 8-inch pot to one of 11 or 12-inches; and of the size of hazel-nuts for smaller ones. The lumps and fibrous parts only should be used, the finer particles being taken out of it by sifting slightly. To each wheelbarrow-load of loam add a 7-inch potful of charcoal of the size of hazel-nuts, another of fresh soot, and the same of bone-meal, turning the heap two or three times so as to mix it thoroughly. Never use a soil without first warming it to as high a degree as that of the hotbed, and it must be slightly moist. The sizes of the pots used will depend upon the variety, the [size and

plants not pot-pound should be repotted into larger pots, badly-rooted plants being repotted in smaller ones after the old soil is shaken from the roots. When placing the ball in the fresh pot, let it be at such a depth that when the work is done, the soil will reach up to that part of the stem whence the leaves spring, and be sure to leave space for holding water 2 inches deep. In repotting, the soil should be put round the ball, a large handful at a time, and make it quite firm from time to time with a blunt-ended potting-stick, and finish off level and smooth. Plunge the pots to three-quarters of their height in the bed, and at such a distance apart as will give them space to grow without getting crowded. Suitable temperatures are for bottom-heat 85° at the base of the pots, and top-heat about 65° at night,

that drip does not reach any plant. Plants that have been resting during the winter, and are now to be started into fruit, may be kept a few degrees warmer than what is recommended for succession plants.

Suckers should remain on the old stools until they are strong and sturdy, and as they reach this state, detach them with a sharp twist. Before potting, trim the base of each smoothly, and strip off a few of the lowermost leaves, and, according to the variety, pot them into 6 or 8-inch pots, and plunge to the rim of the pots in a pit by themselves, or at the front of the succession plants.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Bedding Calceolarias.—The autumn-struck cuttings of these plants that are being harboured in a cold frame will have made much growth, and the points of the leading-shoots should be pinched out in order to ensure a bushy, many-branched form. Let them be afforded a great deal of ventilation whenever the weather is not frosty or wet, even tilting the lights at the back of the frames on mild nights. Do not allow them to get dry at the root, at the same time guard against an excess of moisture. The soil in which the Calceolaria thrives is one which has been liberally manured with rotten dung, and deeply dug; for a frequent cause of the plants dying off in the summer is the poorness of the soil in which they are planted. The best bedding varieties are Golden Gem, Sultan (a dark-flowered variety), and amplexicaulis, the lemon-coloured variety—this is of taller growth than the others and is more adapted for large beds, the only objection to the variety being its lateness in coming into flower.

Carnations.—The time will soon arrive when the plants which have been wintered in frames should be planted in the beds. Carnations are much more effective when each variety has a bed to itself, than when mixed altogether. When, however, the number of any variety is limited, or if in the case of new varieties, massing may not be possible. Amongst the best massing varieties are the following:—crimson and scarlet and white Cloves; Duchess of Fife, of a delicate pink hue, and a good grower, with a compact style of growth, and excellent for cutting; Raby Castle, a deeper pink than the foregoing, with serrated petals—a useful flower; and The Hunter, a dark form of Mrs. Reynolds Hole, the calyx of which does not split like that variety. In yellows, there are Germania, Leander, Pride of Penhurst, and Miss Andry; in scarlets, Aline Newman, Hayes' Scarlet, and Queen of the Bedders; in rose and rose-pink, Mary Morris and Ketton Rose are good; and in whites, Gloire de Nancy; The Pasha, of an apricot colour, is one of the best, and one that for bouquets and buttonholes is always desirable. A Carnation-bed should be moderately manured, and receive a good quantity of road-grit or sharp sand, and charred soil, especially if the soil be heavy and retentive, and by-and-by, when the plants are growing, a slight top-dressing of farm salt will have a good effect on them. The beds should be dug forthwith, and left in a rough state for a week or two before levelling and making it ready for planting.

General Work.—The lawn-grass is growing, and mowing will soon have to be done; and, in any case, the turf must receive a rolling before the machine or scythe are used. The mowing-machine may require repairs, and these should be attended to without delay. It is always best to let the maker have the mower to repair it; and when his factory is in a distant part of the country, a good deal of time elapses before the machine is returned. Sometimes the local smith can put little matters right. Hedges of laurel may be pruned, not allowing these, if possible, to get much top growth, otherwise the hedge gets thin at the bottom. It is good practice to trim the upper portion somewhat severely, although the effect may in some cases be bad for a short time. Stored Gladiolus-corms should first be examined, and then laid out in trays filled with sand so as to fit them for planting out next month. Begonia-tubers for bedding may now be started in a pit or house having a temperature of about 50°, not allowing the heat to become much more than this, or growth will be spindly. Keep bedding Pelargoniums quite free from dead foliage, and begin to afford them a little more water, abundantly ventilating the pits, &c., on warm days. Cuttings of these plants started in warmth may be placed round the edges of 4-inch flower-pots filled with sandy loam, and stood in a house with a warmth of 55°, and close to the glass. Avoid affording these cuttings much water, or much moisture in the air, or damping off will occur.

FIG. 48.—LÆLIA ANCEPS WADDONIENSIS: FLOWERS WHITE, BASE OF LIP YELLOWISH. (SEE P. 124.)

(Photographed for the *Gardeners' Chronicle* by Mr. J. Gregory, Croydon.)

vigour of the plants, 10 to 11-inch pots being suitable for Queen's, and 11 to 12-inch ones for Smooth Cayenne and similar strong growers. Never use a dirty pot, and if new, the pots should be laid in a water-tank for an hour before being used. Large crocks should be used, the concave side downwards, topping these with small ones, the whole making a thickness of 2 to 3 inches; on these put a thin layer of rough soil, and a sprinkling of soot. Plants standing in 6 or 7-inch pots, which are well-rooted, may be potted into 10 and 11-inch, and those in 7 or 8 into a larger size. Before turning them out twist off any visible suckers, and a few of the lowermost leaves. A few days before repotting begins, afford water to all the plants that require any. When a Pine plant is turned out of its pot, carefully remove the crocks and the surface-soil down to the roots, and loosen some of the roots at the sides. Of course, only well-rooted

and 70° on dull days, rising to 85° by sun-heat, and 5° more in the afternoon after closing. Successions may have a bottom-heat of 80°, and 5° less top-heat day and night. Suckers will do very well in the same kind of bottom-heat, or a little less till they obtain roots. Ventilation needs to be carefully afforded during the present season, a small quantity of air being admitted at the top of the house during the warmer hours for a short time only. The fruiting-house, if any of the fruits are ripening, should not be kept very humid, and no water should be afforded to any plant with fruit showing any tinge of yellow; but growing fruits will need water, and occasionally manure-water when the soil is approaching dryness. Damping down may take place once daily for the present, and on sunny days the plants may be dewed over with the syringe at closing time, but not those with colouring fruits; and be careful

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, FEB. 23 { National Chrysanthemum Society's
Annual Meeting at Auderton's
Hotel, Fleet St., E.C., at 7 P.M.

THURSDAY, MARCH 3—Linnean Society Meeting.

SALES.

TUESDAY, MAR. 1 { Roses, Carnations, Dahlias, Gla-
dioli, &c., at Protheroe & Morris'
Rooms.

WEDNESDAY, MAR. 2 { Japanese Lilies, Tuberoses, Gla-
dioli, Palms, Greenhouse Ferns,
&c., at Protheroe & Morris'
Rooms.

THURSDAY, MAR. 3 { Roses, Plants, Fruit Trees, &c., at
Mr. Stevens' Rooms.

FRIDAY, MAR. 4 { Border Plants, Bulbs, Roses, &c.,
at Mr. Stevens' Rooms.

Imported and Established Orchids,
at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from
Observations of Forty-three years, at Chiswick.—49° 7°.

ACTUAL TEMPERATURES:—

PROVINCES.—February 23 (6 P.M.): Max., 45°, Scilly;
Min., 32°, Aberdeen.

Light frost; heavy snow-storm in the west of
England.

The Gardeners'
Benevolent.

GREAT credit is due to the admin-
istrators of this excellent Insti-
tution for the means they took a
few years ago to promote the interests of the
candidates generally, and especially of those
who had been subscribers for a series of
years. A few more concessions in this direc-
tion will remove or materially lessen the
objections and disappointments we now hear
of. After every election we receive a certain
number of complaints, and, indeed, as no
institution is perfect, we look upon them as
more or less inevitable. This year the result
of the ballot seems to have given an unusual
amount of dissatisfaction. Whatever be the
grounds of objection, it is manifest the respon-
sibility for them rests with the voters themselves.
Did they assess the claims of the several candi-
dates before they gave their votes, or did they
not rather give their suffrages to some one they
wished to get in? or perhaps they merely
handed their voting-paper to some friend. The
complaints that have reached us are mostly of
two kinds—one, that non-subscribers have
by the present system of voting an unfair
advantage, and that interest and the exertions of
friends are more potent factors than the claims of
the candidates. It certainly looks like it, and it
affords, to our thinking, a strong argument in
favour of the extension of the plan already
alluded to, by which the committee allots a certain
number of votes to each candidate in proportion
to the length of time and to the amount he has
subscribed. Increase the number of votes so
allotted, and the chances of the subscriber will
be all the greater. This plan is in accordance
with a suggestion from one of our correspon-
dents, that every voter should give two-thirds
of his votes to those who have been subscribers
for a certain period, and the remaining third to
the non-subscribers. We do not think the
voter could be trusted to do this, but the com-
mittee might easily do so.

The next most numerous cases of complaint
do not excite so much sympathy. Mr. A. B.
has been a liberal supporter of the Insti-
tution, and when he finds the candidate
he nominated has not been elected, he feels
aggrieved. We have the greatest possible
respect for the generous donor, and we rejoice to
see his cheques, but we ought not to put his
interests and wishes before the claims of the
aged and the necessitous. If anyone wishes to
secure the election of a particular candidate,
no doubt the committee would gladly arrange
matters with him after consultation with their

actuary as to the amount to be paid to ensure
admission.

For whose benefit does the Society exist?
for that of the voters, or for that of the
necessitous? If every voter would ask himself
this question before signing his paper there
would be a better chance for the immediate
success of the most necessitous.

When those of the candidates have been
elected, who by a sufficient length or amount of
subscription, or by their urgent necessity have
the prior claim, then should come the turn of the
non-subscribers, and of those less-heavily
afflicted. It must always be remembered that
all the candidates are, in the opinion of the com-
mittee, worthy, though the necessities of some
necessarily must be more urgent than others.

Some of our correspondents compare the
benefits to be derived from various friendly
societies, such as the Odd Fellows, with those
to be obtained from the Gardeners' Bene-
volent, much to the detriment of the latter.
We do not know enough about the societies in
question to make comment upon them. It must
suffice, therefore, to say that the object of the
Gardeners' Benevolent is different from that of
the benefit societies. It is for the encourage-
ment of self-help, the alleviation of misfortune
and infirmity, and the exercise of charity to
others less favourably circumstanced; while,
looked at merely as an investment, the pensions
often represent extraordinarily good value much
better we believe than could be obtained
elsewhere.

One correspondent, who characterises as most
ridiculous our suggestion that the committee
should select the candidates according to the
urgency of their claims, and then submit the
list to the voters assembled at the general meet-
ing for confirmation or otherwise, maintains
that it is not possible for the members of the
committee who mostly live in or near London,
to know the merits of those who have spent
their lives in the country. This is very specious,
but it is met by the fact that the committee
does, even now, investigate and make public
the circumstances of each case as it is brought
before it, and its members must of necessity
know more about the relative qualifications of
the whole body of candidates, than anyone else
can do. If the committee do not do their duty
—turn them out. Is their ruling objected to?—
bring the objection before the general meeting,
and let the voters decide the question.

The same correspondent stigmatises as non-
sense the proposal to give more power to the
committee under adequate safeguards. Possibly
it is, but we do not think so, and we do not
think those who know the way in which the
committee does its work will have any such
opinion. Moreover, the same or a similar plan
works well in similar cases, and does not lead
to the same amount of dissatisfaction. In the
meantime, we entirely agree with our corres-
pondent that every effort should be made to
induce gardeners to join early in life, and to
enlist the sympathy and support of their
employers on behalf of a Society which has
effected so much good in the past, and the area
of whose beneficent ministrations happily
extends yearly.

Medallo-mania
at the R.H.S.

THE intention, if not the method
of action of the Council of the
Royal Horticultural Society in
endeavouring to restrain the ridiculous medallo-
mania that has set in, deserves the sympathy
of all those who realise the dignity of their work
or the honour of the Society. There are certain

special societies, which seem to exist for no other
purpose than to give medals or other awards.
There are prizes 1st, 2nd, 3rd, 4th, 5th, in eve
yet more numerous classes, so that scarcely
a competitor or exhibitor can fail to receive a
award of one sort. The Manchester Orchid Society,
as will be seen in our present issue, is also very
profuse in its awards. We had hoped the Royal
Horticultural Society was worked on higher
principles than this. We know as well as most
people what may be, what is, alleged on
behalf of prize-giving, and we acknowledge the
validity of these comments in principle, while
objecting strongly to excessive frittering in detail.

Carefully considered and strictly limited
awards are one thing, lavish distribution of
them quite another; circumstances alter cases
and proceedings which might be harmless or
even beneficial at a village show are out of place
at the exhibitions of the representative Society
of the Kingdom. The main object of awarding
prizes is to promote horticulture, any advantage
that may accrue to the individual is altogether a
secondary matter. The proverbial line is no
doubt as difficult to localise as the boundaries in
an African "hinterland," but where general prin-
ciples are not lost sight of, there need be no
special difficulty in allotting prizes or in with-
holding them, as the case may be. We are not
careful to go into statistics, because the over-
production of medals and awards is palpable
and obvious to every disinterested looker-on.

It might be well that no award of any kind
should be given without the direct assent of at
least two-thirds of the committee, and that a
provisional system of marking, such as is
carried out at Chiswick, according to which
exhibits are marked *, **, or ***
according to their merits, should in many cases
supersede the award of certificates or medals.

Votes of thanks, or special votes of thanks
might also well replace a large number of these
medals. Such courtesies would satisfy many
an amateur, and would in no case be liable to
disparagement, as the medals undoubtedly are
at present, and will be still more if some steps
be not taken to reduce their numbers.

ISCHARUM EXIMIUM.—A very curious and
interesting Aroid from Western Cilicia, where it
grows in loamy soil at certain places in the plain.
The spathe is of a dark black-purple colour on the
upper surface; green, spotted with red on the under
surface. The broad, simple leaves form a pretty
rosette. The fruits ripen under the surface of the
soil as in the case of *Arachis hypogaea*. Fig. 49 shows
the plant growing in its natural locality.

LINNEAN SOCIETY.—On the occasion of the
evening meeting to be held on Thursday, March 3,
1898, at 8 p.m., the following papers will be read:—
1. "On the Sense Organs of the lateral line in certain
Fishes," by Mr. F. J. COLE. 2. "On the occurrence
of *Carex helvola* in Britain," by Mr. G. C. DRUCE,
F.L.S. 3. "An Arctic Spider from Franz Josef
Land," by Rev. A. PICKARD-CAMBRIDGE, M.A., F.R.S.

"KEW BULLETIN."—The November number,
recently received, is mainly taken up with the Report
of the West India Royal Commission, to which notice
has been already drawn in these columns.

GARDENERS' ORPHAN FUND.—The annual
meeting of this useful association was held on Friday,
Feb. 18, at Auderton's Hotel, Fleet Street, WILLIAM
MARSHALL, Esq., in the chair. Among those present
were Messrs. Veitch, Wynne, Poupart, Roupell,
Assbee, Gordon, Wright, Fraser, Jones, Reynolds,
R. Dean, Outram, Cumming, Masters, &c. The pro-
ceedings were of the most formal character, the
members being, as they have reason to be, satisfied
with the work of the committee. The adoption of
the report was proposed from the chair, and seconded
by Mr. Bates. It elicited little discussion beyond
the expression of an opinion that in future it would

FIG. 49.—ISCHARUM EXIMIUM: HARDY AROID, GROWING IN ITS NATIVE LOCALITY IN CILICIA.
(SEE P. 126.)

be well to limit the number of children elected from one family. The treasurer, auditors, committee, and secretary were (with the necessary alterations in the case of the committee) re-elected. The movers or seconders of the several resolutions being Messrs. Poupert and Cuthbert, R. Dean and Roupell, Asabee, May, Cummins, Reynolds, Walker, Jones, and Fraser. After the work of the scrutineers was completed, the members regaled themselves at the usual friendly dinner under the presidency of Mr. W. Marshall. The following children were elected:—

1. AGNES MACINTOSH ...	349 Votes.
2. ROBERT JOHN SMITH ...	332 "
3. JAMESINA BAIRD ...	278 "
4. LYDIA ANNIE MILNE ...	275 "
5. HERMIONE KOSBAB ...	272 "
6. WILLIAM EWART HOLMES...	269 "
7. RUTH AMY WARTH ...	241 "
8. MARGARET ANNIE RICHARDSON	232 "
9. CONSTANCE MARY JAMES ...	209 "
10. ANNIE KATHLEEN FRENCH ...	166 "

(Added by the Committee at the Meeting).

NATIONAL CHRYSANTHEMUM SOCIETY.—The annual meeting of the members of this Society to be held on Monday next is likely to be of great interest, as many important matters connected with management will be discussed. We have received from Mr. J. W. MOORMAN a pamphlet, embodying the views of himself and others (which have been published by the horticultural journals) in respect to the connection of the Society with the Royal Aquarium, which we have always considered to be a most unsuitable locality for the Society. The following questions are asked by Mr. MOORMAN:—

First.—Whether the time has not arrived for the Society to have a paid Secretary, and no vote?

Secondly.—That it be an instruction to the Committee to inquire and report on what other places (if any) can be obtained for our exhibitions, either by a subsidy, as now, or otherwise?

Thirdly.—To consider if the time has not arrived when in reliance on our own resources we can proceed on independent lines like most provincial societies, which are in a sound financial condition?

Fourthly.—As there appears to be much disquietude arising from the fact that the Secretary is the delegated referee at all our exhibitions, whether the advisability of a change should not be considered in the form of a small Reference Committee or otherwise?

Fifthly.—That as the custom of selling the floor space of the Aquarium to trade exhibitors (some of whom are not *bona fide* growers of Chrysanthemums), and that inasmuch as such sales have driven competitive exhibits of Chrysanthemums into semi-dark galleries upstairs, whether such custom of selling space for a different purpose than that for which the National Chrysanthemum Society was established shall be seriously considered with a view to its discontinuance.

Sixthly.—That an Exhibition Committee be appointed to closely examine the question of minor shows with the object of ascertaining their advantages or otherwise, to the Society, and report the results of their investigations to the general committee.

METROPOLITAN PUBLIC GARDENS ASSOCIATION.—The fifteenth annual report of this body is now before us, and we commend it to the attention of all interested in the work of trying to "supply one of the most pressing wants of the poorer districts of London by providing breathing and resting-places for the old, and play-grounds for the young." As a guide to the enterprises undertaken by the Association, it may be mentioned that the successful work accomplished in 1897 including the laying-out of three new gardens, provision of gymnastic apparatus for one play-ground, the erecting of three drinking-fountains, seats in twelve localities, trees in three places, and assistance given in preserving, acquiring, and improving thirteen open spaces.

N. A. PAILLEUX.—The death, on the 8th inst., of this gentleman, in his eighty-sixth year, is announced. M. PAILLEUX took great interest in horticulture, and in the introduction of novelties. It was he who introduced to our gardens what are known as Crosnes or Chinese Artichokes, the first-name being derived from that of the village where M. PAILLEUX resided and distributed the tubers. The book, *Le Potager d'un Curieux*, in which he had the assistance of M. Bois, is a standard book of reference on the rarer culinary plants.

SHIRLEY AND SURROUNDING DISTRICT GARDENERS' AND AMATEURS' MUTUAL IMPROVEMENT ASSOCIATION.—The monthly meeting of the above was held at the Parish Room, Shirley, Southampton, on the 21st inst., the President presiding over a fair attendance of members, when Mr. E. T. MELLOR, Lecturer in Biology to the Hartley College, Southampton, gave his second and concluding lecture on Fungi, this part being on "Injurious and Beneficial Fungi."

OSTRYA CARPINIFOLIA.—The death of what was probably the finest tree of its kind in the kingdom is announced in the *Kew Bulletin*. The tree was figured in the *Gardeners' Chronicle*, September 30, 1890; and in *LOUDON'S Arboretum* in 1838. The dimensions of this tree which grew near to the Economic House, were:—Height, 59 feet; spread of branches, 68 feet; girth of trunk 3 feet from the ground, 9 feet 4 inches. Fruit was abundantly produced, but no perfect seeds were formed.

A CHOICE GATHERING FROM ABBOTSBURY.—From Abbotsbury, near Dorchester, we have received, through the kindness of Mr. BENBOW, an interesting collection of flowers grown out of doors, and including Rhododendrons, Camellias with the black-green leaves that gardeners like to see, *Acacia dealbata*, *Fatsia japonica* represented by a candelabrum-like arrangement of branches of ivory-white colour, bearing at the end globular heads of berries like those of the Ivy, *Ilex Perado* with its bright green obovate leaves and abundant stalked flowers, its relative *I. diphyrena* with narrow lanceolate leaves and dense clusters of nearly sessile greenish flowers, *Vaccinium ovatum* with branchlets spreading nearly at right angles to the stem, and small, nearly sessile, deep green leaves, the flowers axillary pendulous, *Drimys Winteri* with red shoots and lanceolate deep green above, pale beneath, and terminal panicles of greenish flowers, specially interesting to the botanist; *D. aromatica*, with much narrower leaves but otherwise similar; *Pittosporum bicolor*, a small tree with narrow, rose-mary-like leaves, and solitary, axillary, pendulous, somewhat bell-shaped flowers, with recurved sepals and petals tinged with red. The tree is 22 feet high, 12 feet through, with a girth of 12 inches at the ground level.

THE ROYAL CALEDONIAN HORTICULTURAL SOCIETY.—At a meeting held on Wednesday, 16th inst., appointed Mr. P. MURRAY THOMSON, S.S.C., their secretary and treasurer, out of seventy-eight applicants. Mr. THOMAS GORDON, County Rooms, Edinburgh, was in the final vote with him, and lost it by one vote.

PUBLICATIONS RECEIVED.—Royal Botanic Gardens, Glasnevin, Dublin, *Seed List*.—Supplement to new creations, Fruit and Flowers, LUTHER BURBANK, Santa Rosa, Sonora County, California. In this are offered "Apple," "America," and "Charles" Plums, the Pearl Prune, hybrid Walnut Paradox, surpassing all others in rapidity of growth, and recommended as a timber tree; hybrid Walnut "Royal" produces nuts in abundance; Rose hybrid "Bourbon Tea."—*The Amateur World of Horticulture*. This is the "Record of the Proceedings of the National Amateur Gardeners' Association" for October to December, 1897, and gives a satisfactory record of progress.—*Transactions of the Royal Scottish Arboricultural Society* (vol. vx., Part II.) contains the President's Address; Forestry Education, by Dr. W. SCHLICH; Forestry in Scotland in the Reign of Queen Victoria; Experiments with Tree-seeds, and other papers of interest.—*Excursions of the Royal Scottish Arboricultural Society*. These excursions were made to Dublin, Powerscourt, Coollatten, Carton, and Killarney, and to Dolphin-ton, in 1897. The record of them is not merely pleasant reading, but has a present value, likely to increase with time, in that the dimensions are given of many of the more noteworthy or famous trees visited. As these measurements are not mentioned casually but carefully tabulated, it will be comparatively easy for future generations to make similar observations and test them by these standards of comparison.

ORCHIDS AT OAKWOOD, WYLAŃ.

BEAUTIFUL as are the many fine hybrid and cross-bred Orchids raised by Norman C. Cookson, Esq., assisted by his gardener, Mr. William Murray, the fine show of beautiful flowers of the Popayan varieties of *Cattleya Trianaei* now giving brilliancy to the *Cattleya-house* at Oakwood, causes one to imagine that among Orchids, either of hybrid origin or in species, nothing can be found to equal them for showiness. The flowers noticed vary from pure white with a faint blush of colour on the lip, to white with purple blotch; and some few are almost entirely of a bright pink colour, though the majority belong to the dark, richly-coloured forms, and of these the hue of the lip varies from crimson to ruby-red and purple, the edge being generally prettily crimped and margined with white. About these plants Mr. Cookson relates a curious experience. They flowered last year for the first time, and although the flowers were passable, they were considered to be nothing remarkable. But as many of the *Cattleyas* did not thrive to his satisfaction, Mr. Cookson resolved to alter his treatment, and he began by raising the plants nearer to the roof-glass, affording more ventilation, and making alterations in the method of heating, with a view to securing a more even temperature, and the house fitted with wood-lath roller blinds, besides a few other points that were attended to. The result has been that the plants which appeared unsatisfactory last year are now in magnificent health. The *Cattleya* show is being followed by a display of the hybrid *Dendrobiums* raised on the place, the first to open its flowers being the handsome *D. × Owenianum*, the clear white, and dark purple-hued *D. × Murrayi*; the soft rose-coloured *D. × Dulce*, Oakwood variety; *D. × Harold* and *D. × Sibyl*, two very bright and profuse-flowering kinds; *D. nobile* Cooksoni, and others of these curiously varied plants. Of the species of *Dendrobium* which are not considered free growers, but which here seem only in danger of flowering themselves to death, were noted, *D. Johnsoniae*, *D. atro-violaceum*, and *D. McCarthiae*, the last named being one of the first plants bought by Mr. Cookson, and it grows and flowers still very freely, and has had the additional strain of seed-bearing to endure on several occasions.

Of the new things in flower the finest is *Phaius × Norman* (*P. Sanderianus × P. tuberculosus*), which is even handsomer and larger than *P. × Cooksoni*, especially the lip. Three crosses, obtained from different parents, are represented in the batch. Some of the plants possess flowers of a large size, with chrome-yellow sepals and petals, over which a very peculiar salmon-coloured shade spreads; some have cream-coloured sepals and petals; and some are rose-coloured, with the base of the lip in each case of a reddish-purple veined with yellow, and the front portion of various shades of rose and purple, varying in intensity in the various flowers, but always attractively arranged. The old plant of *Phaius tuberculosus*, which has supplied the means of securing this variety in the colouring, and the other fine crosses, still maintains its vigour unabated, though in most gardens the plant is considered, and found to be, one of the worst plants to cultivate successfully for any length of time.

Among the *Cypripediums* a handsome hybrid between *C. Spicerianum* and *C. Fairieanum* is flowering; also *C. × Io × Fairieanum*; a number of the fine *C. × Calypso*, Oakwood variety; *C. × Juno*; the beautiful *C. × Ceres*, and *C. × delicatulum*, all three first raised by Mr. Drewett; *C. × alium*, *C. × Cyrus*, *C. × vexillarium*, and two singular pallid forms, the one of *C. × Godseffianum*, and the other of *C. × Pitcherianum*, both seedling varieties. The hybrid *Calanthes* exhibited a goodly number of plants in flower, the best of which are *C. × Sibyl*, pure white; *C. × splendens*, carmine-crimson; *C. × Wm. Murray*, a large cream-white flower, with maroon blotch; *C. × Bryan*, and *C. × Phœbus*, a very large and richly coloured flower of the *C. × Veitchi* section. Of the hybrids of *Phaius* and *Calanthe* that are in flower, there were noted *Phaiocalanthe × grandis* (*P. grandifolius × C. Bryan*) with a vigorous

spike of showy blush-white flowers, having a dark claret-hued face to the openly displayed lip; and the fine *Lælio-Cattleya* × *Doris*, whose rich yellow flowers and rose-purple tip to the lip always receive attention. The varieties of *Lælia anceps*, I was informed, have flowered unusually freely this year; and, as in some other gardens, some grand forms of the *L. a. Schroderiana* section have been noticed.

The warm-house contains a small collection of *Phalænopsis* that is doing well, and some of the *P. Schilleriana* are in flower; also some fine specimens of *Coelogyne cristata alba*, *C. c. Lemoniana*, and other varieties.

The occupants of the *Odontoglossum*-house are in their usual vigour, and as a proof that they are not degenerating, the rare spotted kinds are steadily increased, the handsomely-blotched *O. crispum* Cooksoni, numbering eight plants, all of which were propagated from the original plant. Plants of other fine varieties of *O. crispum*, *O. Pescatorei*, and others are in bloom; and among the *Masdevallias*, *M. × Courtauldiana*, *M. Shuttleworthi*, *M. Veitchigigantea*, and others appear.

In a cold frame, a fine display of seedling *Hellebores*, covered with flowers, and which Mr. Cookson considers quite the best tolerably hardy flowers of the season, was remarked. Evidences of the earliness of the season were noted in quantities of *Primroses* and other spring flowers.

BELGIUM.

THE BRUSSELS ORCHIDÉENNE.

At the meeting of this Society, held on Feb. 13, there were shown as many as eighty-five Orchids. Among them were specimens of *Cattleya Trianaei* and *Odontoglossum* from MM. Lucien Linden & Cie. of Moortebeke, and from L'Horticulture Internationale. The most splendid *Cattleya*, which obtained a First-class Diploma of Honour, *par acclamation*, was dedicated by M. Linden to his late father, and named *C. Trianaei memoria Lindeni*. The plant is remarkable for form, and rich and velvety colouring, and resembles *C. Imperator*, though differing from it in some respects. The lip is especially noticeable for the deep uniform purple colouring, distinct and difficult to describe exactly. Many other fine varieties of *C. Trianaei* gained Awards.

Among the *Odontoglossums* was *O. sulphureum*, which gained a First-class Certificate à l'unanimité. It bears a very long branching raceme, with many flowers, which are white, edged with sulphur-yellow, and slightly speckled. Another novelty of the *O. Ruckerianum* class is much speckled, and has a large marking on the lip, a variety of *crispum*, has very close flowers, much crimped and united in a dense cluster.

From Moortebeck and Brussels came the following plants:—*Mesospinidium vulcanicum grandiflorum*, a very fine variety of unusual colouring; *Oncidium Phalænopsis*, three forms, one with white flowers, much speckled on the three superior divisions, and slightly on the base of the lip; another with a lilacy lip, very curious; and the third with, on the superior sepal, one very dark spot delicately edged with white; the other divisions much spotted, the lip pure white. *Lælia præstans alba* (First-class Diploma of Honour), has a spreading flower, pure white, lip pale lilacy-rose at the top.

There were also some five varieties of *Cypripedium* *Victoriæ Mariæ*, *C. Argus*, prettily marked, wide petals, with numerous large spots; *Saccolabium giganteum album* (very white); *Eulophiella Kegel-jani* (First-class Diploma of Honour), a curious and charming novelty, flower triangular, of an apple-green colour, marked with concentric lines.

The Comte de Bousies sent a vigorous specimen of *Miltonopsis Bleuana* var. *nobilior* with eight large and handsome flowers, and seven buds borne on three clusters (Diploma of Honour *par acclamation*).

M. Miteau exhibited a good variety of his *Cypripedium Pauli*, named *eximium*.

M. du Trieu de Terdonck obtained a Diploma of

Honour for *Cypripedium Spicerianum* × *Boxalli atratum*, much admired by specialists.

M. de Lombærde showed some dark varieties, the most velvety were like *Lælia anceps* (Diploma of Honour).

M. Florent Pauwels showed *Odontoglossum Warszewiczii*, always rare; *Lælia anceps alba*, a good variety, with a large fine white flower; and *Odontoglossum Rossi majus*, with flowers nearly four inches across. M. Arthur Morren (brother of the late M. Edouard Morren), sent a pretty *Cattleya Trianaei albescens* with a slightly rosy lip.

THE BELGIAN ORDER OF LEOPOLD.

The following have been lately promoted to the rank of officer of the Order of Leopold: MM. Cartuyvels, Minister of Agriculture; H. Van Hulle, Honorary Professor at the Ghent École d'horticulture; and Ch. Van Wambeke, President of the Vigilance Committee of the said École. The following have been made Chevaliers of the Order: MM. Giele, Director of the Louvain Botanic Garden; Griffon, Professor at the Tournai École d'horticulture; Jules Hye-Leysen, nurseryman of Ghent, and Sels nurseryman of Duffel. *Ch. De B.*

NURSERY NOTES.

MESSRS. J. CHARLESWORTH AND CO.,
HEATON, BRADFORD.

So rapid has been the progress of hybridising Orchids in this nursery, that a large part of a block of houses has been set aside for cultivation of the seedlings, and another range erected in order to afford space for the large number that are approaching a flowering age. The numerous array of minute plants, each mounted on its stand, and carefully labelled, present the orderly appearance of battalions of soldiers.

No crosses likely to produce indifferent results are carried out, and only the best varieties, and where possible with plants not previously used, are crossed. *Lælia Digbyana* has been crossed at Heaton with many showy and some very dissimilar species, and a few plants of most of the crosses made have resulted. *Epidendrum radicans* also has received much attention and crosses with it, and various species of *Cattleyas* and *Lælias*, are approaching a flowering age. As was remarked by Mr. Veitch, most of the widely different species crossed with *Epidendrum radicans* produce plants that closely resemble the pollen-parent in growth, which curiously differ from the seed-bearer. Among the experimental crosses are plants whose parents were so very unlikely to give good results that the raiser scarcely cares to mention their names before the flowers have been produced.

Among the showy imported Orchids is a very fine group consisting of a good type of *Cattleya Trianaei*; a grand lot of *Cattleya aurea*; a number of compact plants of the best large-flowered type of *C. Mendeli*; a still greater number of *Cattleya Mossiæ*, which although imported only a year ago are without an exception about to flower profusely.

In the *Dendrobium*-house the plants showed much vigour; and in flower we noticed the handsome-looking *Dendrobium × splendidissimum* Leeanum; several good *D. × s. grandiflorum*, and other varieties of the *D. × Ainsworthii* class; fine varieties of *D. nobile*, of which the natural hybrid *D. Rolfeæ* has made marvellous flowering growths; *D. × Cassiope*, and hybrids of it; *D. Wardianum*, and many other species. In one of the houses was a small batch of white-flowered *Cattleyas*, viz., *C. Mossiæ Wagneri*, *C. Gaskelliana*, &c.; in another we remarked a selection of fine varieties of *Odontoglossum crispum*; some large plants of *Miltonia Endresii*, *M. Phalænopsis*, and one of *M. vexillaria* Leopoldi; and in another a large number of *Odontoglossum cirrhosum* and other species of *Odontoglossum* was in bloom, as well as a smaller number of *Oncidium macranthum*. Other plants observed were *Lælia purpurata*, in sheath; *Vanda coerulea*, *Lycaste Skinneri*, *Brassia*

Lawrenceana, fine varieties of *Lælia anceps*, a fine lot of hybrid *Cypripediums*, and handsome varieties of *C. Charlesworthi*, *C. Rothschildianum*, &c.; a few fine plants of the rare *Cymbidium grandiflorum*, and the dwarf *C. tigrinum*; the curious *Pleurothallis Roylei*, with racemes of large blackish-purple flowers, the handsome *Masdevallia Winniana*, and other *Masdevallias* of the *Chimara* section, also many curious Orchids and other plants. The singular looking pitcher-plant *Heliamphora nutans* was noted among the latter. The nursery is compact and well kept, and anything likely to be of benefit to the plants seems to be put into practice. At the present time the floors or walks of the houses are being put in good order, and the flooring-tiles are being removed and shingle used in its place.

TREE-PLANTING ON HAMPSTEAD HEATH.

THE Parks and Open Spaces Committee of the London County Council have just issued a report with reference to their action in planting trees on certain parts of Hampstead Heath. They point out that a scheme for planting Parliament Hill, the East Park, and part of Hampstead Heath, east of Spaniards Road, was approved by the Council, and carried out during 1895 and 1896. Objection having been made to the trees planted near the Willow Road and the Spaniards Road, on the ground that as they grew they might obstruct the views towards Highgate and London, the committee pointed out to the objectors that the trees near the Willow Road were intended to take the place of Willow-trees planted by the lord of the manor forty years ago, which were fast decaying, while those near the Spaniards Road were ornamental, and were intended to check the scour of the fine sand which, owing to the decay and disappearance of the coarse grass and Gorse on the steep slopes between the road and the Vale of Health, washed down in great quantities after rain and choked the storm water-pipes. Trees of light foliage were here preferred, such as Birch and Mountain Ash, which would not interfere with the growth of Gorse, Broom, and Briar. In planting the trees, care had been taken not to interfere with vistas and distant views. On visiting the heath last autumn, the committee found that while 1190 trees were planted under the scheme on the East Heath, and 994 on Parliament Hill, 49 had died and been removed, and 23 had been transplanted to meet the wishes of residents. The Fir plantations on the heath, planted by the Metropolitan Board of Works about 1870, were also being thinned, and about 100 trees removed east of the Spaniards Road, and about 90 trees on the west and north-west heaths. The subsoil of Hampstead Heath consisted principally of fine Bagshot sand, and, owing to the increased use of the heath, and the consequent wearing away of the coarse grass and Gorse, it had been found very difficult to preserve the undulating character of the Heath. Where the sand was exposed, every storm washed considerable quantities of it from the hillocks into the hollows. The best way of checking this scour of the sand was to plant suitable trees and grasses where the gradients were steep; and it was in order to encourage the growth of Gorse that they were advised in 1895 to cut out the dead wood in the Gorse plants, which were blackened and sickly owing to the severe frost. It was a mistake to suppose that trees were not suited to Hampstead Heath, as they had always flourished there, and they afforded food and shelter to song birds, which were now found to be returning to the Heath owing to the operation of the Wild Birds Protection Act. *Times.*

ALLOTMENTS AT EYNSFORD.

SPEAKING at a technical education meeting at Eynsford (Kent) recently, Mr. E. D. Till explained that, although there was a most interesting exhibition in an adjoining room, the interest of the evening chiefly centred around the Cup given by Mr. H. M. Pollett, because it commemorated William Howard's sixty years' tenure of his Eynsford allotment. All were deeply indebted to Sir Percival Hart Dyke, Bart., the grandfather of the present M.P., for initiating the allotment system in Eynsford. They were also indebted to the public spirit of Mr. Pollett for bestowing the Silver Cup; but, after all, it was the enterprise and industry of William Howard which attracted hearts that evening. Although the Cup records the jubilee period of sixty years, it was nevertheless sixty-six years since Howard trenched his allotment. He planted his Winter Queening sixty years ago, and the sieve of fruit now before them was but a small sample of this year's crop. Mr. Till said he could not do better than quote Howard's own words, which quaintly connected cause with effect, in reference to the Winter Queenings: "If I hadn't a' planted that 'ere tree, shouldn't a' had all this here fruit!"

Mr. Cannell congratulated Mr. Howard on his long and successful tenure. What an amount of pleasure and of profit, physical and mental, said the speaker, must the cultivation of this allotment have given to Howard in the course of so many years! What wholesome food for himself and his family! The very look of this veteran parishioner (see fig. 50) (said he) testified to the benefits of allotment culture. Mr. Cannell hoped that so excellent an example would not be lost upon the lads present, and that they in their turn would be able in their old age to reap, in one shape or another, fruit that never fails to result from sowing and planting wisely in youth. He had the greatest possible pleasure in now handing the handsome Pollett cup to Howard, and, at the same time, paying a well-deserved compliment to the donor.

Mr. William Howard, in a few pathetic words, then said how thankful he felt to the donor, and to those present, for the honour they had done him. He spoke of his endeavour to treat his allotment well, and how he had regularly removed the earth round his tree, and treated it to a good dressing of manure.

Howard's youngest son (Elvey) then, on his own behalf, and that of his brothers and sisters, testified to the great pleasure this gift to their father occasioned them. He could remember well, many years ago, how that, in one especially hard winter the produce of his father's allotment had helped to provide most needful food for the family. His elder brothers had had to seek their livelihood outside the village, one as an inspector in the docks, and the other in the Army. The latter was at the gallant defence of Rorke's Drift, and is now enjoying Her Majesty's pension. Mr. Elvey Howard spoke with considerable effect on the advantages of technical education, and how he himself had reaped some of its benefits.

The following is the form of agreement between Howard and the landlord, Sir Percival Hart Dyke:—

"Sir Percival Hart Dyke agrees to permit the Persons now holding Slips of Land at the Parish of Eynsford, Kent, to continue to occupy the same so long as they comply with the following Conditions; but if any of the said Conditions cease to be complied with, the person so doing to give up the Land within Two Months after he has received notice to quit the same; being Paid for what produce he may leave behind him on the Ground, except in the case of Theft or Wilful Damage to any of his Neighbours, in either of which cases to be subject to immediate ejectment without any remuneration:—

To Pay a Rent of Five Shillings Yearly, on the First day of June, half on the First day of October.

To Sufficiently Manure the Ground once in every Two Years.

Always to Sow a spot with Turnips Sufficient for the use of his family.

Never to commit any Damage on the Ground occupied by others.

Never to underlet any part or to make Sale of his own Produce to the injury of his Family.

Not to continue in the occupation of the Ground if he removes his Residence to a distance inconvenient for its cultivation.

Never to work it on Sundays.

Mark x of Wm. Howard.

Witness: A. Killick.

October 4, 1831."

HOME CORRESPONDENCE.

ROYAL GEORGE APPLE.—It is always a good thing to verify a statement, a quotation, or a fact. Very necessary is this in the case of the names of Apples, for a duplication or more of names for the same variety is little short of a nuisance, and it certainly makes confusion where there ought to be no mistakes. I therefore take the liberty of saying that to the best of my knowledge, the Apple Royal George, mentioned by Mr. G. Bolas in the *Gardeners' Chronicle* of February 19, p. 116, is identical with Clarke's Seedling, now being sent out by two of our Midland nurserymen, the Messrs. Pearson of Chilwell, and Mr. Merryweather of Southwell. The Messrs. Pearson in their list give it its alternate name in brackets, and possibly either Mr. A. H. Pearson or Mr. Henry Merryweather could tell us something of its history. My contribution to that history is this, thirty years ago, and for many years afterwards, I

was one of the judges at the East Bridgeford Horticultural Society's show, which is always held on the last Tuesday in June. Invariably amongst the dishes of Apples to be judged of those of "Last year's Apples," would be set up beautiful samples of this Royal George Apple, and on my making enquiries in the village concerning its origin, I was told that it was raised by a Mr. Clarke; and, indeed, I was taken to see the original tree with fruit then growing upon it. Hence therefore its birthplace is East Bridgeford, in Notts, and its raiser Mr. Clarke. East Bridgeford, though only a small village, is noted for early Potatoes and other market garden productions sent to the Nottingham market. The situation is high and dry, and the place stands well out of the valley of the Trent, and looks south-eastwards into the Vale of Belvoir. Whether the fertility of the soil there is due to the cultivation given to it by the Romans is, of course, a debatable question, but the village certainly stands on the site of the ancient Roman city of Margiddunum, and the old fosse-road from the south to the north (Bath to Lincoln and York) is only a mile or two away. *N. H. Pownall, Lenton Hall Gardens, Nottingham.*

STERNBERGIA MACRANTHA.—S. Arnott says, in *Gardeners' Chronicle*, p. 116, that *Sternbergia lutea*

FIG. 50.—W. HOWARD, AND THE SILVER CUP.
Presented to him after sixty-six years' tenancy of his allotment, and sixty-one years since he planted above Apple-tree.
(See p. 128.)
(From a photograph by J. Gregory Croydon.)

does not flower freely in every garden. In the Berlin Botanic garden it is a free-flowering species, which produces flowers every year in October in great masses, and as the flowers last till the New Year, it is a very valuable plant. Indeed, I found the flowers covered with snow without any harm. Where the plant does not flower freely, certainly it has no suitable situation. Mr. Arnott is quite right when he says that *S. lutea* requires a thorough "roasting" in summer. In our garden the bulbs are planted out in a light, rich, humous sandy soil, together with other Liliaceæ and Amaryllidaceæ. This place is quite open, so that the sun may shine upon it during the summer with all its power. In all such places *S. lutea* and also *S. macrantha* will flower very well. *U. D.*

FISH AS MANURE.—During the time I have been foreman in these gardens, a quantity of fish-refuse from a fishmonger's shop has been brought to the kitchen garden, and buried in trenches—in fact, the ground has been manured with it. Various crops have been grown, but I have never seen anything extraordinary about the results, only just an average crop. I should be glad of any information on this subject of manuring with fish. In digging, the bones turn up for several years, and the ground is filled for some time with grubs, which rooks and starlings are very partial to. If there is not much benefit to be derived from it, I would discontinue its use. *C. Blake, The Gardens, Charlton House, Old Charlton.*

THE ROYAL HORTICULTURAL SOCIETY'S AWARDS.—The literally vital importance of this question to the Royal Horticultural Society, seems to be little understood. The particular form of the direction sent down to the committees by the Council on February 8, may have been ill-judged, but it was obviously intended as nothing other than a practical emphasizing of the opinion concerning the Society's awards already expressed, with the most conciliatory moderation, in the annual report. This report had been in the hands of every committee-man for some time previous to February 8, and should have served as an interpretation of the Council's directions to the committees, and prevented any offence. It is greatly to be hoped that the entire Society will support the Council in its general and most true contention, that the awards have been far too lavishly bestowed. In the one year 1897-98, no fewer than 531 medals were awarded. It is not saying too much to assert that half this total would exceed what should be given annually if a Royal Horticultural Society medal is to be a real token of unquestionable excellence. The same thing may be said of the Awards of Merit—346 in a year is a number which robs the award of all valuable significance. Periodically there is made in the press an onslaught on the Royal Horticultural Society as being, in fact, little more than a very flourishing Metropolitan Florists' Mutual Admiration Society. To rebut this charge, the Council has of late made earnest efforts to extend the Society's operations to the provinces, and there are glimpses of such a field opening out as may enormously increase its usefulness. But unless measures are speedily taken to restrict this suicidal cheapening of the Society's Awards the old reproach will be justified, and little store will be set, a field, on prizes which are so easily gained at home. Of course, there are difficulties. It is no secret that the commonly whispered reply to the critic is—"Oh, yes, all very true, but then we have the trade to consider; if we give fewer medals we shall offend the trade, and where should we be without the trade?" In short, the vicious circle once complete, the Society is to trudge round in it for ever. Is it true, after all, that by restoring to the Awards their proper office of recognition of true distinction we should offend the trade? The trade have a most excellent subscription's worth in the simple advertisement of what may be called their ordinary wares once a fortnight in the Drill Hall, and there is little fear of their withdrawal if they did not on every occasion receive the Award of Extraordinary Merit for what are very good wares, but not always extraordinary. I have many friends among the trade, and may perhaps claim to know enough of their views on this point to feel assurance that few of them would resent a very considerable restriction of these awards. I was recently shown by one nurseryman a whole drawful of medals, with a gesture of little less than contempt. On another occasion I urged a rising provincial florist to exhibit his specialty at the Royal Horticultural Society meetings, as he would undoubtedly obtain awards. His reply was—I remember his precise words—"Of what use is it to me to get a medal that any one can get by showing any kind of stuff, if he shows enough of it?" This was no doubt an exaggeration; nevertheless it represents a truth, and a truth that is very clearly perceived by a large public outside the Royal Horticultural Society. The Society is, or should be, essentially an educational Society, and the first requisite for every educational Society is that its standard must be a high one. Its numbers and finances may be augmented, and its members pleased all round, by acquiescence in a low standard, but the acquiescence will admit the seeds of ultimate decay. It was a comfortable and flourishing class of private school which sent every boy home with a handsome prize, but not the class which endured, or raised the education of the country. To philosophize in this way does not solve the practical difficulties which face the committees in effecting the reduction, nor am I now attempting the solution, but only pointing to the deep importance of the issue, and urging every member of the Royal Hort. Soc. to support the council. If this support is given, a satisfactory solution will certainly be found. *A. B. C.*

—The Council must again express their opinion that there still appears to be a tendency to multiply unduly the awards recommended, and they earnestly request the several committees to consider seriously whether there is not a real danger of impairing the value of these distinctions by such increase of their number, and whether it would not be possible as well as politic to, be somewhat less generous in recommendation of awards during the ensuing year." The above is part of a paragraph

quoted from the report of the Council for the past year. From the same report I find it stated that there were twenty exhibitions of fruit and flowers held at the Drill Hall, Westminster, and that fifteen committee meetings were held at Chiswick Gardens. It is well known to those who have the privilege of attending these meetings at the Drill Hall, that each meeting has now become not a dry and technical gathering, convened specially in order that experts may examine, criticise, and report upon some new or rare plants or fruit put before them. It is true the meetings are all this; but they are a great deal more. Each meeting can become a veritable flower-show, none of them of large proportions, and all of them full of interest and instruction; and as far as educational influence bearing on the higher aspects of horticulture, there are no exhibitions in the kingdom to compare with them. The Floral Committee alone had, I believe, over 1200 distinct and meritorious subjects placed before it in the course of last year, every one of which, in the opinion of the exhibitor, being deserving of the highest award. Without agreeing with this, I venture to say, as not an infrequent attendant, that the best of most things, whether new or old, finds its way to the Drill Hall at one time or another. It has not been publicly stated that the cost of these awards are any bar to their being granted; but I would like to draw your readers' attention for one moment to the cost to the Society of the awards made to the various subjects exhibited at these twenty meetings at the Drill Hall, and the fifteen committee meetings at Chiswick. It is £371, not mentioning odd sums, scarcely the amount given at one good provincial show, which only works out at about £10 12s. for each meeting. Surely, on the score of cost, no demerit can reasonably be made by the council, or by anyone else. All of these thirty-five meetings put together only cost about one-half as much as the Temple Show, or what is spent on the *Journal* of the society, the latter costing £608. I submit then, that on the score of cost, the case against the medals and awards must be abandoned. Now, what about the plea of the danger of impairing the value of the distinctions conferred by their too liberal bestowal as contended by the council and others. I know full well that the council have perfect confidence in its committees, and appreciate their services to the full, and I also know with what care each member is selected for his skill and eminence in the work of the committee upon which he is selected to sit. It is almost superfluous to say that there is not a gentleman on any of the committees who would recommend any exhibit for an award which, in his opinion, did not justly deserve one on its merits. Granting, then, that the qualifications of the members of the committees are beyond reproach, I submit that it is next to impossible for them to err in making their awards; and if they do err, where is the body coming from which is able to impeach and rectify their judgment? If the awards are not to be made in accordance with the judgment of the various committees, on what other principle, may I ask, are they to be made? If a departure is thought necessary, I see nothing for it but to adopt the retrograde movement of giving points instead of awards, as suggested by a correspondent in one of your contemporaries last week. This would effectually lessen the number of awards, and, as I believe, the number and value of the exhibits as well. The members of the committees seem to have had a rather hard time of it lately. I see it is advocated in some quarters that members should be compelled to vote on every subject placed before them, whether they liked it or not. I hope the Council will not listen to this unwise suggestion, for if there were a mechanical rule made, it would remain a dead letter from the first, as no member of a committee could be compelled to vote if he did not think well to do so voluntarily. On the whole, the committees do their work well, and deservedly command and receive the confidence and approval of British horticulturists generally; and the Council, in my humble opinion, will be well advised "to let well alone." The one chief cause for the increase in the number and value of the awards is to be found in the increased number, and in the improved quality of the exhibits brought before the Society, and for this, if there is blame to be attached, the Society itself is responsible. The Society is growing in popularity, wealth, and usefulness, and whilst these conditions continue, so will its exhibitions improve in quality and increase in extent, and, as a natural consequence, its awards also. *Looker On.*

LAUDANUM.—Rev. C. Wolley Dod (*Gardeners' Chronicle*, Feb. 19, p. 116) says that the biographer

of Paracelsus attributed to that physician the introduction of opium into general use. Opium, however, was known and used probably many hundreds of years B.C.; the metaphorical expression of Jeremiah (viii, 14), "He hath put us to silence and given us the water of gall to drink," would appear to refer to the well-known effects of opium; gall being in Hebrew, *rōsh*, a "head." Theophrastus, in the third century B.C., knew it under the name Meconion, and Pliny (*Nat. Hist.*, xx. 76) described how opium was extracted from Poppyheads and made into lozenges. He, too, speaks of its soporific and fatal effects. Matthæus Sylvaticus (A.D. 1480) speaks of several kinds of opium; but opium simply is always that of the Poppy. Salmon, in his *English Physician* (A.D. 1693), describes several sorts of "Laudanums," with or without opium; as an ingredient in opposition to "the true extract or spirit of opium," made from choice samples. The imaginary derivation from "laudandum," to be praised, is given by Thicknesse in his *Treatise on Vegetables* (A.D. 1749, p. 387) as follows:—"Prepared opium is called in the shops laudanum. This name was first given it by Paracelsus, from the word Laudandum, as being a medicine which deserves praise. The fact is, that laudanum is the Spanish form of Labdanum. Minshen's *Spanish Dictionary* (A.D. 1623) has "Laudans, the gum Labdanum, used in pomanders," *ab* becomes *av*, then *au*. The word itself is Persian, and occurs in Pliny, but the transference to the opium of the Poppy appears to have taken place in the fifteenth or sixteenth century. Perhaps Paracelsus, who lived in the fifteenth century, adapted the word to the opium. *George Henslow.*

PLANTS IN BLOOM IN THE OPEN AIR, ST. VALENTINE'S DAY.—In a lady's garden in the midland counties the following plants were in bloom at the date given above:—Twenty varieties of *Helleborus*, red, white, green, purple, and cream coloured; *Milla* (*Triteleia*) *uniflora*, white; do., blue (changed by peat); *Rhododendron dauricum*, *R. præcox*, *Clematis calycina*, on wall; *Forsythia Fortunei*, on wall; *F. suspensa*, border; *Lonicera fragrantissima*, wall; *Chimonanthus fragrans*, wall; *Jasminum nudiflorum*, wall; *Daphne Mezereum* and the white variety, *D. laureola*, *Cornus mas*, *Laurustinus*, *Cydonia japonica* (wall), *Spiræa Thunbergii*, *Berberis fascicularis*, *B. japonicus*, *Hamamelis arborea*, *Erica codonodes*, *E. herbacea carnea*, *E. h. alba*, *Erythroniums* in variety; *Crocus*, in beds, all colours, "Thackeray" very fine; *Snowdrops* in variety, *Anemone blanda* (green), *A. fulgens*; white *Hyacinths*, in full bloom; *La Tour d'Auvergne*, as early as the forced bulbs; *Hepaticas*, four varieties; *Megasea Saxifrage*, two varieties; *S. oppositifolia major*, very effective; *Chionodoxa Lucilæ*, *C. sardensis*, *Scillas taurica*, *passiflora*, and *sibirica*; *Bulbocodium vernum*, *Omphalodes verna*, *Vinca minor*, blue and white; *Symphytum orientale* (white Comfrey), *Pulmonaria sibirica*, *Narcissus minor* (Daffodil), *Primroses*, all the winter; *Potentilla alba*, all the winter; *Muscari*, *Hyacinthus botryoides* and *H. neglectum multiflorus*; *Aubrietias*, two varieties; and *Arabis procera*. *H. M. G.*

FREESIAS.—Mr. Kerry, writing on these plants in the *Gardeners' Chronicle* on the 12th inst., asks readers of the paper to tell him the greatest number of flowers which have been produced on a scape. I have grown *Freesias* abroad for the last three years, with the following results. The bulbs to which I refer were grown in the open ground, and as such, the results are better than those cultivated in pots. Their habit of growth under out-of-door conditions is much sturdier, and the tendency of the flower-spike to branch much more marked. I make out that *Freesia Leichtlini major* is more floriferous, and gives more flowers on a scape than *F. refracta alba*. Maximum number of flowers on a scape, 17; average number of flowers on fair-sized bulbs, 12 to 15; maximum number of flowers from one bulb, 136; average number of flowers, 70 to 110. The bulbs had from 7 to 10 laterals. In the case of the bulbs which gave 136 flowers, the flower-spike seemed to divide into two, almost from the apex of the bulbs. *W. H. Wallace.*

LILIUM AURATUM.—We have dug up this winter, at Oakwood, some large beds of *Lilium auratum* which had not been disturbed for ten years; many of the Lily stems were browned by a hard frost late in last May, which lasted all night. We found many fine bulbs, and more small ones, from large bulbs having broken up. We found also a good many cockchafer grubs, and a greater number of a long white narrow grub, which an eminent entomologist

tells me "are the grubs of the small Swift-moth (*Hepialus lupulinus*), a destructive creature of anything underground." After this experience, I would advise examining parts of large Lily-beds every winter so as to be sure that grubs are not present in quantity. *Geo. F. Wilson.*

BRITISH NURSERYMEN AND ENTERPRISE.—With reference to the invitation, on p. 58 of the *Gard. Chron.*, to the leading seed-growers of the country to furnish information as to the work of English producers of seeds abroad, permit me to say that my house has for upwards of half-a-century been engaged in exporting seeds to all parts of the world. I publish seed catalogues in French, and my representatives are actively engaged in travelling in that country, as well as through the United States. I have recently dispatched a consignment of seeds for His Imperial Majesty The Emperor of Japan. Notwithstanding the heavy import duty imposed on English-grown seeds by some countries, and the great obstacles placed in the way of trade by others, I have every hope that English seed-growers will not only hold their own but prove to the world that English seeds are unequalled. *John K. King.* [This correspondence must now cease. Ed.]

GROS COLMAR GRAPES.—The well-ripened bunches will keep sound for a long time with the ends of the shoots inserted in bottles nearly filled with rain-water, if not kept too dry and warm. I think a Grape-room should not be so warm and dry as to cause shrivelling, and I have had bunches of Lady Downe's Seedling in splendid condition in an average temperature of 40°, and even a degree or two lower. Bunches of Grapes that are kept in a very cool place should be placed in a warmer temperature before partaking of them, the berries, on removal to a warm room, having a hazy appearance. As showing how Gros Colmar Grape varies in quality under cultivation and soil, or both combined, I was instructed to send some cuttings of a Vine of this variety growing at Mereworth to be propagated and planted elsewhere in a new range of vineries, and the difference was so marked with regard to the skins and flavour, that the late Lord Falmouth was somewhat loth to believe that they were raised from the Mereworth Vines. *H. Markham, Northdown, Margate.*

PASSIFLORA EDULIS.—This plant is largely cultivated in Australia, and the fruits appear in all fruiterers' shops. Some persons eat it with cream, as we eat Strawberries. It is grown on trellises and over porches, in which positions the plant has a nice appearance, as also when trained over a continuous arcade along a garden-walk. If an espalier be shaken, the ripe fruits only drop to the ground. I am cultivating the plant out-of-doors in a sheltered position, and hope to have some success to record this year. *Frank Lilley, St. Peter's, Guernsey.*

THE MILDNESS OF THE SEASON AT BELVOIR CASTLE.—January was one of the most remarkable months of recent years, the mean temperature at this place was 41°, as against an average mean of 35°, which was therefore more like that for the month of March. Many tender plants commenced to grow and flower owing to the unusual increase in temperature. Tea Roses on the castle walls made young growths 6 inches in length before the end of the month, as did also that beautiful shrub *Photinia serrulata*, and the twining *Muehlenbeckia complexa*—the latter is a native of New Zealand, and was much injured here in the severe frost of February, 1895. Gloire de Dijon and crimson China Roses have not ceased flowering since last May. *Chimonanthus fragrans* and *Lonicera fragrantissima* were full of flower by the middle of January, and *Ceanothus azureus* has continued in flower throughout the winter. *Acacia dealbata*, *Melanthus major*, *Eucalyptus globulus*, *Centaurea candidissima*, and *Cineraria acanthifolia*, have survived outside since May, 1895, and *Albizia lophantha*, *Eupatorium odoratum*, and *Grevillea robusta* have lived since May last, in the open air unprotected. *Prunus pissardi* commenced flowering on January 31, *Doronicum excelsum* on January 28, but only four inches high instead of three feet, as if expecting the cold winds of March. *Anemone fulgens* commenced on the 15th, and has since yielded hundreds of its beautiful scarlet flowers. St. Brigid's strain of *Anemone coronaria* has also proved this year a very useful flower for cutting. The double-flowered Violet, Lady Hume Campbell, has been flowering from the beginning of winter; as have the beautiful Harbinger Primroses, raised by the late Mr. R.

Gilbert of Burghley House. All of the plants in the spring flower-beds are unusually forward. The flower-buds of Camellias and Himalayan Rhododendrons which have flourished outside here for many years, are fortunately not much advanced, and this is fortunate, for we do not know what is in store for us in the matter of weather. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

SOCIETIES.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

FEBRUARY 10.—The meeting of the above Society was held in the Coal Exchange, Market Place, Manchester, the following members of the Committee being present:—Messrs. W. Thompson (Chairman), J. Cypher, W. Stevens, G. W. Law-Schofield, J. Leemann, W. Bolton, S. Gratrix, R. Johnson, W. A. Gent, J. Backhouse, H. Greenwood, and P. Weathers.

Both in point of quantity and quality the meeting was an excellent one, and no fewer than seventy-eight subjects were dealt with by the committee, seventeen of which received First-class Certificates, and thirty-one Awards of Merit.

From Mr. G. W. LAW-SCHOFIELD (gr., Mr. Schill) came *Cypripedium* "G. W. Law-Schofield," a charming hybrid the parentage of which is unrecorded, but *C. bellatulum* was undoubtedly used in its raising, the whole flower was a rich purplish colour, and well formed (First-class Certificate). *Cypripedium Lathamianum giganteum* (Award of Merit), *Dendrobium* × *Juno* (Award of Merit), (*Wardianum* × *Findlayanum* and *Dendrobium* × *xanthocentrum* (*Ainsworthii* × *Findlayanum* (First-class Certificate). Mr. T. B. RAPPART, Lisard (gr., Mr. Nicholson), sent *Dendrobium* × *Schneiderianum*.

Mr. T. STATTER, Whitefield (gr., Mr. R. Johnson), sent *Cypripedium villosum giganteum*, a splendid form of the type, and certainly well named (First-class Certificate). *Dendrobium splendissimum grandiflorum* was well shown, and received an Award of Merit. *Dendrobium splendissimum giganteum* from the same collection was very fine, and is of very great distinction (Award of Merit). *D. nobile Amesiae*, the charming variety with white segments, now so well known, received a First-class Certificate. *D. Schneiderianum* received an Award of Merit.

Mr. H. H. BOLTON, Newchurch (gr., Mr. Eastwood), exhibited *Dendrobium* × *Rainbow* (*Findlayanum* × *Ainsworthii*), and it was much admired by the committee, who voted it an unanimous First-class Certificate. *Dendrobium nobile* var. *burfordiense* came from the same collection; it is a variety with the two lower sepals splashed with purple, and is distinct (Award of Merit). Mr. S. ALLEN, Sale, exhibited a good form of *Cattleya Trianaei*.

Mr. W. THOMPSON, Stone (gr., Mr. Stevens), took premier honours, showing four plants, each of which obtained First-class Certificates; undoubtedly the finest thing was his *Odontoglossum* × *excellens* var. *spectabile*, a plant bearing a splendid spike of flowers, which were beautifully formed and well marked. *O. crispum candidissimum* was also very fine, being an ordinary well-formed *crispum*, with the snowiest of white colour; the cultivation of this plant in particular excels anything the writer has seen, either at home or abroad. *Odontoglossum nebulosum candidulum* proved to be an exceptionally beautiful and distinct variety, and deserved the recognition it gained. *Cattleya amethystoglossa* was shown in a splendid specimen, with a huge inflorescence.

Mr. J. CYPHER, Cheltenham, put up a few very nice plants, out of which the committee chose *Zygopetalum crinitum superbum*, *Cattleya Trianaei Gratrixe*, *C. Trianaei superba*, *Dendrobium Ainsworthii* (Cypher's variety), and *Dendrobium splendissimum Lceanum*, each of which gained an Award of Merit. Mr. J. ROBSON, Altrincham, exhibited *Cattleya Trianaei bella*, *Cattleya Trianaei formosa*, and *Cymbidium eburneum giganteum*, the latter receiving an Award of Merit.

Mr. T. SWINBURNE, Winchester (gr., Mr. Rendall), exhibited *Cypripedium* × *Mons. de Curte* (Swinburne's var.), an excellent hybrid, for which an Award of Merit was given; also a good plant of *Cypripedium villosum giganteum*, which, however, is not so well developed as Mr. Statter's.

Mr. J. LEEMANN, Heaton Mersey, made a fine display of good things, among which were *Laelia anceps Williamsii* (Award of Merit), *Cattleya Trianaei alba* (Award of Merit), *Dendrobium nobile Sanderianum*, in beautiful condition (First-class Certificate), *Dendrobium nobile Ballianum* (Award of Merit), *Cattleya Trianaei*, a very handsome and well-coloured form (Award of Merit), *Odontoglossum Andersonianum* var. (Award of Merit), and Cultural Certificate for a huge specimen of *Cypripedium Haynaldianum*.

Mr. G. SHORLAND BALL, Wilmslow (gr., Mr. Hay), exhibited a very fine form of *Cattleya Trianaei*, the purest of white, and it was awarded a First-class Certificate; *Dendrobium Wardianum* var. *ochroleucum*, a plant of sterling merit, and extremely scarce (First-class Certificate); *Dendrobium Wardianum album* received an Award of Merit. Mr. BALL also staged a pretty pan of *Dendrobium glumaceum*. Mr. HARRY GREENWOOD, Haslingden sent a nice form of *Dendrobium Schneiderianum*.

Mr. S. GRATRIX, Manchester (gr., Mr. McLeod), put up a few nice plants, among which was a very fine form of *Cypripedium* × *Prewettii*, Award of Merit; also *Cypripedium* × *signatum*, a distinct and useful hybrid, Award of Merit; and a similar award was gained for *Dendrobium* × *enosmum leucopetrum*.

Mr. A. A. PEETERS, Brussels, exhibited a superb hybrid *Zygopetalum*, viz., *Perrenondi* (intermedium × *Gauthieri*), a decided acquisition to the large family of hybrids, First-class Certificate. A First-class Certificate was also given for a good *Odontoglossum Wilckeianum*. M. PEETERS also sent a new *Sophronites* called *Rossiterianum*, a small orange-coloured species which, when seen in a more advanced stage should prove interesting.

Mr. W. BOLTON, Warrington (gr., Mr. Cain), exhibited a good form of *Dendrobium Wardianum album*, for which a First-class Certificate was granted; *Dendrobium* × *Robinsonianum* (Award of Merit); *Cattleya labiata* var. *Boltoni*, a dark variety, splashed (Award of Merit); and a First-class Certificate for a fine form of *Cattleya Trianaei*.

Mr. O. O. WRIGLEY, Bury (gr., Mr. Rogers), gained an Award of Merit for *Cypripedium Lathamianum* var. *aureum giganteum*.

Messrs. F. SANDER & Co., St. Albans, exhibited a splendid form of *Cypripedium* × *Fascinator* (Award of Merit); also a very interesting plant of *Lycaste Mooreana*, with flowers very suggestive of those of *Coeloglyne pandurata* (Award of Merit). And the same firm received a First-class Certificate for a fine hybrid *Cypripedium*, unnamed, parents being *C. Calypso* × *villosum aureum*. P. W.

BOURNEMOUTH AND DISTRICT GARDENERS'.

FEBRUARY 15.—In the presence of a large number of members and friends, Mr. ARTHUR W. SUTTON, F.L.S., delivered a lecture on the above date, entitled "Potatoes Past, Present, and Future." In the absence through illness of the President (Mr. T. J. Hankinson), the chair was taken by Mr. A. Skinner, Highcliffe Castle Gardens.

A large number of lime-light illustrations, showing various species and varieties of *Solanum*, experiments in grafting and disease prevention carried out at Reading, and examples of some of the highest types of Potatoes in cultivation at the present time, gave additional interest to the lecture.

The subjects remarked upon by Mr. Sutton were as follow:—The introduction of the Potato—Reference to the Potato by early writers—Various tuber-bearing species of *Solanum*—Gerarde's Description of the Potato in 1636—Area of Land under Potato Cultivation—Method of Planting, Raising, and Storing, 100 years ago—Implements used 100 years ago—Implements used at the present day—Deterioration and Improvements—Disease Prevention—Bouillie Bordelaise—Raising Seedlings—Species and Varieties—Monstrosities—Axillary Tuberculation—*Solanum Maglia*—Hybridisation—Modern Varieties—Grafting—Potatoes and Tomatoes on one Plant—Conclusion.

CARDIFF AND COUNTY HORTICULTURAL.

FEBRUARY 21.—The Annual General Meeting of this society was held on the above date, under the presidency of Mr. W. C. PEACE. The following officers were appointed:—President, The Mayor; Vice-Presidents, Alderman W. J. Trounce, J.P., Alderman E. Beavan, J.P., Mr. W. C. Peace, and F. G. Treseeder; Executive Committee, Chairman, Mr. A. E. Dixon; Vice-Chairman, A. W. Pike, and Messrs. A. M. Bailey, J. W. Boon, S. Medhurst, E. J. Harley, T. Grimes, C. Wightwick, with Mr. H. Gillett as Secretary. The Annual Show will be held on July 20 and 21.

NATIONAL CHRYSANTHEMUM.

FEBRUARY 21.—At a meeting of the general committee on the above date, a report stated that the position of certain new varieties of Chrysanthemums had been considered, and that the following were admitted as incurred varieties:—Austin Cannell, Ernest Cannell, General Mauric, Lady Isabel, Lyne Junior, Middle Lucie Faure, Madame Ferlat, M. Desblanc, Owen's Crimson, W. Carpenter, Yvonne Desblanc, and Mrs. N. Molyneux. The votes in favour of these being so classified were practically unanimous. Harold Wells and Sir T. Lawrence were, by small majorities, accepted as incurred. The subject of "too-much-alike" blooms, especially in the incurved section, was then considered, and a recommendation from the classification committee in relation thereto discussed, the object being to inform exhibitors that the blooms in classes for distinct varieties must be sufficiently diverse to be readily distinguished by the judges, or the stand will be disqualified. The report was afterwards referred to the classification committee that a list of varieties too much alike might be added.

A draft report of a decidedly optimistic character was read by the Secretary, and after a little conversation, was adopted in its entirety for presentation at the annual general meeting.

READING AND DISTRICT GARDENERS' ASSOCIATION.

FEBRUARY 21.—The fortnightly meeting of the above Association was held in the Club-room, British Workman, on

Monday last, the President, Mr. C. B. STEVENS, presiding over a good attendance of members. The subject for the evening was "A Chat about Melons," introduced by Mr. B. Dockerill, The Gardens, Elmhurst, Reading, a well-known grower and successful exhibitor of this fruit. The paper was of the most practical nature, and dealt with the cultivation of the Melon in all its branches. Mr. Dockerill said he was obliged to condense a large subject into a small paper, but trusted that it would be sufficient to open up a good discussion on the principal points worth considering. Some excellent blooms, equal in quality to those seen in November, of Mrs. E. W. Clarke and J. H. Taylor Chrysanthemums were on view.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named: and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

DISTRICTS.	TEMPERATURE.					RAINFALL.		BRIGHT SUN.

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

THE following summary record of the weather throughout the British Islands for the week ending February 19, is furnished from the Meteorological Office:—

"The weather continued mild and fair over the greater part of the kingdom during the first half of the period, and was again mild and rainy in the extreme north and north-west. After Wednesday, however, it became much colder, and showers of cold rain or sleet were experienced in all parts of the kingdom.

"The temperature was again above the mean, as a whole, the excess ranging from 4° in 'England, S. and S.W.' and the 'Channel Islands,' to 1° in 'Scotland, N.' The highest of the maxima were registered at most stations on the 15th, and ranged from 59° in 'Scotland, E.' and 57° in 'England, N.E.' and 'Ireland, S.' to 52° in 'Scotland, N.' The lowest of the minima were recorded on Saturday, when the thermometer fell to 22° in 'England, S.W.,' 24° in 'Ireland, S.,' 23° in the 'Midland Counties' and 'Scotland, W.,' 29° in 'Ireland, N.,' and to 37° in the 'Channel Islands.'

"The rain/fall was again much above the mean in 'Scotland, N.,' and was slightly in excess in 'England, N.W.' and 'Ireland, N.' Elsewhere the fall, though greater than that of last week, was again less than the normal.

"The bright sunshine was deficient over the kingdom generally, but somewhat exceeded the mean in 'Scotland, N.,' and 'W.' and 'England, N.E.' The percentage of possible duration ranged from 29 in the 'Channel Islands,' and 28 in 'Scotland, E.,' to 16 in 'Ireland, S.,' 13 in 'Ireland, N.,' and 12 in 'Scotland, N.'

VARIORUM.

NEW PALM-HOUSE FOR LIVERPOOL.—Mr. Henry Yates Thompson, of Bryanston Square, London, and Thingwall Hall, near Liverpool, on Wednesday, 23rd inst., arranged to provide for Stanley Park, Liverpool, a Palm-house somewhat similar to one he placed in Sefton Park in the same city in 1896, of which we gave a figure on July 18, 1896. The Sefton Park Palm-house and its plants cost over £12,000. That for Stanley Park will be about 120 feet long, and will cost about £6000. Mr. Thompson waited upon the Parks and Gardens Committee of the Corporation on the 23rd inst., with Mr. Mackenzie, of the firm of Mackenzie & Moncur, horticultural builders, Edinburgh, who submitted the plans of the structure which the firm will build. Mr. Thompson was warmly thanked by the Lord Mayor and Alderman Ball, chairman of the committee.

POTATO TESTS IN CHESHIRE.—The Cheshire County Council have issued a report of a series of experiments in Potato-growing, which they carried out at the Agricultural and Horticultural School, Holmes Chapel, last year. The manure applied to the Potato crop in these tests was a particularly well-balanced one, and was as follows:—Farmyard manure, 15 tons; super-phosphate (35 per cent. soluble), 4 cwt.; kainit (12 per cent. of potash), 1 cwt.; sulphate of ammonia (98 per cent. purity) $\frac{3}{4}$ cwt. Of the early varieties, the Early Market Favourite came out best with a total yield of 10 tons 13 $\frac{1}{2}$ cwt. per acre. Of the second earlies, Findlay's Challenge came out best with a total yield of 14 tons 7 cwt. per acre, Beauty of Bute, Findlay's Conquest, and Findlay's British Queen all being only a few cwt. behind the winner. Of the late varieties, Findlay's Up-to-Date was a clear first with a total yield of 17 tons 13 $\frac{1}{2}$ cwt. per acre, Maddock's Hough Giant being second with a total yield of 16 tons 7 cwt. per acre. The Cheshire experimenters also devoted some experiments towards solving the question as to whether it was better to plant whole sets than cut sets, but they are evidently not quite certain as to the results; and they give it as their opinion that, before a definite conclusion can be drawn, these experiments will have to be carried on for a number of years, and with a good many varieties of Potatoes. "*North-British Agriculturist*," Feb. 12, 1898.

AMERICAN PEARL TUBEROSE: *Novice, Chadwell Heath.* Pot one tuber in one pot, a 48, and if possible of that deep kind called a Hyacinth-pot. Use loam enriched with decayed manure or leaf-mould, and if it be retentive loam, put a small quantity of sand with it. Sink the bulb $\frac{1}{2}$ of its depth in the soil, and if the latter is moist afford no water, and place in bottom heat of 70° to 75°, and do not afford water till growth ensues. If the sun shines brightly, shade them, and syringe lightly once or twice a day according to the state of the weather. If the bulbs are plunged in a hot bed of leaves, or leaves and stable dung, sufficient moisture will be retained in or imparted to the soil to start them without affording water. They do not require starting in the dark, like Hyacinths.

COCKROACHES: *G. M. K.* The Ballinkrain Antidote is sold by Messrs. Cross & Sons, Hope Street, Glasgow; this firm should advertise this capital destroyer more generally.

CYMBIDIUM ALOEFOLIUM: *Veritas.* The flowering season is spring and early summer.

GARDENIA BLOOMS DROPPING: *A. E. F.* Some fault of management is the cause of the dropping of the blooms; but as you afford no particulars of your methods, we will indicate those that are found to be successful with all of the species. To pot the plants in loam and peat in equal proportions, adding a small quantity of decayed manure, and

enough sharp sand as will give a certain degree of porosity to the soil. Potting should be done firmly, the plants not afforded very large shifts, and the last shift should be given whilst there is sufficient time for growth to be made and matured and the roots to fill the pot before the growing season comes to an end. Whilst making growth, bottom-heat of 75° to 80° is a help, but it is not essential. Stopping of the shoots may take place twice during growth, and manure-water occasionally is helpful, varying it with applications of clear soot-water. When growth is finished, remove from the stove-pit to one 5° to 7° cooler, and let the plants remain therein till they are wanted to bloom, when a change back again to stove warmth will cause the buds to expand, provided these were set during the latter part of the growing season. Enough water should be afforded whilst the plants are resting in the cooler house to keep them healthy and prevent the flower-buds from dropping, but not so much as would prevent resting; and equally so in the hotter house where the blooms are to expand, as it is not at that time but after flowering is over that growth should be encouraged. Repotting and pruning should be performed after flowering. The plants should be kept clean by syringing them with soap-suds and petroleum, a wine-glass of the latter to one gallon of suds and kept stirred; and every day, once or twice, as the needs of the plant may indicate, the syringe and clean rain-water should be in request during the period of growth. Scarcely any shading from the sun's rays is required. Sometimes eel-worms attack the roots, bringing the plants into bad health. Can you send some pieces for examination.

MINERAL MANURE: *Constant Reader.* Nitrate of soda.

NAMES OF FRUITS: *W. B.* Golden Reineette, much bruised.—*A. L. S.* Too late to determine with certainty. 1, probably Small's Admirable; 2, Annie Elizabeth; 3, Bramley's Seedling; 5, French Crab.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*J. Souza.* *Cajanus indicus.*—*M. H. T.* 1, a species of Juniper, we cannot tell which in its immature condition; 2, *Coccoloba platycladon*; 3, *Lycopodium Hookeri*; 4, *Mesembryanthemum barbatum*.—*S. D.* The plant is commonly known in gardens as *Begonia glaucophylla*. It is also sometimes called *B. fagifolia*. It is an excellent plant for large suspended baskets, and for covering back walls in warm plant-houses.—*A. L. B.* *Iris tuberosa*, figured in *Gardeners' Chronicle*, May 23, 1885, p. 672.—*W. C.* 1, *Berberis Bealei*; 2, *Berberis aquifolium*; 3, *Berberis Darwinii*, *Pinus insignis*.—*F. M. M.* 1, *Oncidium sarcodes*; 2, *Leptotes (Tetramicra) bicolor*; 3, *Lælia cinnabarina*.—*T. H. D., Chorley.* 1, *Cypripedium Savageanum*, pale variety; 2, *Cypripedium polystigmaticum*; 3, *Cypripedium Harrisianum roseum*; 4, one of the forms of *C. Harrisianum*; 5, *Cypripedium cœnanthum*; 6, *Cypripedium grande*; 7, *C. Harrisianum* variety; 8, *C. Harrisianum* variety; 9, *Phaius Wallichii*; 10, *Cypripedium chloroneurum*, one of the very earliest hybrids; 11, not developed. Probably *C. cœnanthum superbum*.—*H. C., Sevenoaks.* The *Amaryllis* you send has occasionally appeared in gardens. It is known as *Hippeastrum (Amaryllis) Alberti*. It is doubtless a double form of *H. equestre*.—*H. Jenkyns,* *Cornus mas*.—*L. C. Masdevallia melanopus.*

PEACH-BUDS DEAD: *A. Y.* We should advise you to look to the roots, that being doubtless the seat of the trouble. It is a common occurrence for Peaches growing in dry borders to cast their flower and wood-buds, but this is something quite different.

PRIMULA SINENSIS, DOUBLE-FLOWED: *C. B. W.* When bloom is over, put the plants close together on a spent or nearly-spent hot-bed, filling in between and close around the stems with chopped sphagnum-moss, peat, and sand, and keep moderately moist and closely shaded from strong sunshine till the offshoots push roots into these materials, when the former should be detached and potted into a somewhat similar mixture, but with a little more peat. Thumb-pots will be large enough for most of them at the first, keep close for a week or longer in a frame; after that lapse of time, gradually accustoming the plants to more air. They will do in a cold frame facing west or north

during the summer. The plants will come into small 48's by repeated shifts by the end of the growing season.

SOLANUM CAPSICASTRUM: *Novice, Chadwell Heath.* The plants, having been kept dry may be cut back considerably, say, to one-half the length of the shoots, and afforded water to thoroughly wet the soil, and be stood near the glass and away from the heating apparatus in a warm greenhouse of 50° to 55° of warmth. When the new growths burst forth, turn them out, knock much of the soil away, cut back the roots a little, and repot in smaller pots, using rich sandy loam, and pottling firmly. Be not over liberal with water at root till these permeate the soil, but moisten the tops once a day in fine weather, and do not let red spider infest them. They will do very well under greenhouse treatment when April is out. Let the shoots be stopped once or twice, if you like very bushy, compact plants, otherwise stopping will not be needed; and we think plants with long, graceful racemes of berries are the prettier objects. Cuttings may be made from the young shoots; they strike readily in a hotbed. You may rub the seeds out of the fruits in hot water, and after drying them they may be sown in pots of sandy soil put in a moderately warm pit or frame to germinate, taking them out as soon as a true leaf is made. These and cuttings may be treated similarly to the old plants, potting them on by degrees till they arrive in 7-inch pots. Seeds may be sown in March, and cuttings rooted again in about two months' time, if a succession of plants be needed.

SOYA BEAN: *W. S.* This particular Bean would only succeed in this country in unusually warm seasons, and few seedsmen catalogue it, though they would doubtless procure it for you. In any case, seeds may be obtained from M.M. Vilmorin & Co., 24, Mark Lane, London, E.C.

TOMATOS: *J. D.* You would do well to buy a Manual on Tomato Cultivation. A very useful one is Mr. Ravenscroft's, published by Mr. Upcott Gill, 171, Strand, W.C., at the price, we believe, of 1s.

TOMATO HAM GREEN FAVOURITE: *W. J. S.* In extra warm summers it crops abundantly out-of-doors in the open quarter, and against a south wall it is generally a success.

VINE LEAVES: *J. Shaw.* The Vine leaves are attacked by a fungus called *Sclerotinia Fuckeliana*. The summer form of the fungus—once called *Botrytis cinerea*—occurs on the leaves under the form of a brown mould, and in some instances, where neglected, also attacks the flowers and fruit. Spray the Vines once a fortnight with a solution of potassium sulphide, half an ounce to a gallon of water. The spraying should be repeated next year, commencing as the leaf-buds expand, and repeat at intervals during the season. This treatment is absolutely necessary, as myriads of fungus-spores are certain to remain over the winter, and inoculate the leaves next season if not prevented by spraying. All leaves attacked by the fungus should be collected and burned, and theinery should be kept perfectly clean, as the fungus grows readily on dead fallen leaves, &c. *G. Massee.*

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper, MORE THAN DOUBLED, and that it continues to increase weekly.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

(For Markets see p. xiii.)

THE

Gardeners' Chronicle.

SATURDAY, MARCH 5, 1898.

EARLY HERBALS.

TO the lay mind a "herbal" will suggest nothing more than the irrepressible Culpepper, whose work, it is true, has practically held the market for nearly two and a half centuries. Mr. Culpepper may justly claim—were he still in the land of the living—a greater popularity and a larger vogue than all the other kindred writers put together; but there were "herbals" nevertheless long before he wrote. An extraordinary collection of very early examples, dating chiefly before the year 1500, is to come under the hammer at Sotheby's sale-room in Wellington Street, London, on March 23, and a few particulars concerning the more interesting may not be out of place in these columns.

The most important lot of all is, perhaps, a French MS. of the fifteenth century, entitled *Le Livre des Simples Médicines, suivi d'un Recueil de Recettes*, &c.; this MS. extends to 314 leaves, partly vellum, and partly paper, and is ornamented with many hundred coloured drawings of plants, fishes, insects, &c. Manuscripts of this character are very uncommon. The next great rarity is a copy of the work, entitled *Arbolayre Contetât la Qualitey et virtus Proprietez des Herbes*, &c., printed at Lyons by M. Husz about the year 1485. This book, of which the only other copy known is in the Bibliothèque Nationale at Paris, is described by Brunet as a "volume précieux," and it has numerous fine woodcuts, including the full-page one of the botanists in council; it is a translation of the German *Herbal* printed at Bale.

There are copies of three editions of the *Buch der Natur*. The earliest was printed at Augsburg, by J. Bamler, in 1475, and is distinguished by its numerous fine full-page woodcuts in the style of the block-books, coloured by a contemporary artist. This edition was a favourite one with the late William Morris, who, in his article on the woodcut books of Ulm and Augsburg, thus speaks of it:—"With many full-page cuts of much interest. It has full-page cuts of animals, herbs, and human figures exceedingly quaint, but for the most part very well designed; a half-figure of a bishop 'in pontificalibus' is particularly bold and happy." The second edition of this book, which is almost as rare as the first, appeared in 1478, and it differs from the *editio princeps*, chiefly in being "set" in another type, and in the ornamental initials not being in outline. The third copy is from the Augsburg press of Hans Schonsberger, 1499, whilst the cuts are copies of those in the first edition, with the addition of two others from the Strassburg *Hortus Sanitatis*, circa 1490. There are three editions of the *Ruralium Commodorum* of P. de Crescentus, a celebrated treatise on agriculture, the earliest being from the press of Schüssler, Augsburg, 1471, the

other two being printed in 1486 and 1490 respectively.

Of that exceedingly popular book, *Glanville De Proprietatibus Rerum*, there is a fine and large copy printed in the type used by Richel & Wensler at Bale, and it was probably printed about 1470. Not so early, but from a typographical point of view even more interesting, is the fine copy of the *Herbarius sive Aggregator*, from the press of Peter Schœffer, the earliest with a date, 1484; it has 150 numbered woodcuts of herbs in contemporary colouring, the names in Latin and German, and the text in Latin. Following this example from the press of Schœffer, comes a large copy of the *Herbarius Patanie*, 1485, which is a close copy of the last-mentioned work; it also has 150 cuts of herbs in contemporary colouring, and was probably printed at Passau by Conrad Stahel. Of the three editions of *Herbolarium de virtutibus herbarum*, all printed at Venice, the most important is that dated 1491, and printed by L. de Basilea and G. de Papia; it is very rare, and has numerous coloured woodcuts. Although it bears the names of Arnoldus de Novavilla and Avicenna on the title, they are not the authors of the work, and are merely referred to in the preface.

The editions of the *Hortus Sanitatis* start with the extremely rare first edition in German of this celebrated herbal, which forms the basis of Meidenbach's enlarged Latin edition; it was printed by Schœffer at Mainz in 1485; it contains over 300 woodcuts of plants and animals, including a fine frontispiece of botanists in council, in contemporary colouring. The Strasburg editions of Pryss, about 1487, and Beck, of about 1490, are each represented by a copy, the latter being an especially fine one, and is noteworthy for its numerous spirited woodcuts of farming and gardening operations, flowers, &c. The Mainz edition from the press of J. Meydenbach, 1491, "per J. de Cuba," is almost uncut, and contains numerous large and small woodcuts, uncoloured. The series ends with a copy of Gaza's first edition of Theophrastus, *De Plantarum historia libri et de causis plantarum, libri vi.*, 1483.

Following this very interesting collection of early herbals comes a valuable and extensive collection of books relating to gardening, flowers, &c., in 150 lots. The books are principally treatises published in the sixteenth, seventeenth, and eighteenth centuries, chiefly in French, English, and Latin. Some are very rare, and nearly all are choice copies, whilst the collection is one which could only have been formed after many years of diligent seeking. To those interested in the literature of gardening, the collection is one of very unusual interest. *W. Roberts.*

THE FLORA OF THE AZORES.

THE connection between the Missouri Botanical Garden and the Azorean or Hawk Islands, seems rather remote, yet the greater part of the eighth annual report of this garden is devoted to the description and illustration of the Flora of the Azores. Dr. Trelease, the Director of the garden in question, has spent two vacations in the islands; hence the connection. But before commenting on his *Botanical Observations*, a few words on the position and the history of botanical discovery in the islands.

Although generally included in the map of Africa, and by botanical geographers considered as forming an outlying fragment of the

Canary and Madeiran flora, the Azores belong to Europe, being situated about 700 miles from the coast of Portugal, and almost centrally traversed by the 38th parallel of latitude. There are nine islands, in three groups, having an aggregate area of about 700 square miles. They are of volcanic origin, and St. Michael's, which will be associated with Oranges by our older readers, and with Pine-apples by our newer clients, is the largest, and its highest peaks are from 3000 to 3500 feet high. The heights are chiefly covered with *Erica azorica*, *Juniperus brevifolia*, and *Myrica Faya*. Pico is next in size to St. Michael's, and was named from its extinct volcano, which rises to a height of 7600 feet, the summit being bare of vegetation.

As explained further on, a very large proportion of the plants are common to Europe, and the only reason for uniting the Azores botanically with the Canaries is, that the two groups possess two Laurels (*Persea canariensis** and *P. indica*) in common.

Francis Masson, the first of many collectors sent out under the advice and direction of Sir Joseph Banks, to collect seeds and plants for the Royal Gardens at Kew, landed on one or more of the islands on his first voyage to the Cape of Good Hope, and sent home a few things. This was in 1772, shortly after the accomplishment of Cook's first voyage, in which Banks took part, and which, mainly through his exertions and far-seeing sagacity, resulted in such splendid developments in horticulture and colonisation. Masson's stay in the island was a very brief one, and he did not, we believe, procure any of the specially interesting endemic plants, but he was apparently the first of a long line of botanists who have successfully visited the islands. It is true that the French botanist, Adanson, spent time there on his return in 1757, from Senegal, but all his plants were destroyed on a stormy passage, of two months' duration, thence to Brest. Among the few plants introduced by Masson were *Hypericum foliosum*, *Erythraea Massoni*, *Cynoglossum pictum*, and *Myrica Faya*, described by Aiton in the *Hortus Kewensis*.

In 1838, the Hochstetters, father and son, visited the islands, and made considerable collections, which were elaborated in Seubert's *Flora Azorica*, illustrated by fourteen quarto plates, chiefly of endemic plants. This was followed, in 1866, by H. Drouet's *Catalogue de la Flores des Iles Azores*, preceded by a narrative of a voyage in that archipelago; and in 1870, by F. Du Cane Godman's *Natural History of the Azores, or Western Islands*. The botany of the last was written by H. C. Watson, the author of the *Cybele Britannica*, who had himself botanised some of the islands. All three of the publications named are good, but the last is more nearly complete and more critical than its predecessors, and of course more useful to the English reader. It contains an account of the position and physical characteristics of the islands, and much other interesting matter; but is not illustrated. This in its turn has been followed, though not superseded, by the American work referred to above. Indeed, each of these works supplements the others, but neither contains descriptions of all the species. Each contains descriptions of the assumed new species, and as Seubert's *Flora* was first, it contains the largest number of descriptions. Out of 400 species, including cellular cryptogams, he estimated fifty to be endemic; 316, European;

* Dr. Trelease treats the Azorean form as a distinct species.

twenty-three, Canarian or Madeiran; five, African (and not European); and six, American. Since then, many rectifications and some additions have been made. Watson's enumeration of the flowering plants and Ferns brings the number up to 478, whereof forty are regarded as endemic. Watson gives a geographical tabulation of all the species, showing the extension to Europe, Madeira, Canaries, and America, and those which only occur in Africa and the Azores. I have mentioned that Seubert gives five species as African—that is, extending to Africa only; and the most striking fact in Watson's table is the small number (10) that extend to Africa, but not to Europe. *Cakile americana* and *Solidago sempervirens*, two seaside plants, are otherwise restricted to America, though the former is so near our native *C. maritima* as to be included in it by many botanists. Watson also gives a list of Azorean plants common to Madeira or the Canaries, but not found in Europe. Excluding a few that are evidently colonists in both groups of islands, they number about thirty; among them, *Ilex perado*, *Hedera canariensis*, *Notelæa excelsa*, *Laurus canariensis*, *Persea indica*, and *Myrica Faya*.

Dr. Trelease's account of the *Botany of the Azores*, which has been most liberally distributed, has also been issued separately, forming an octavo volume of 145 pages, with fifty-five plates. Unfortunately, the author has not summarised his work, so that it is difficult to form a correct idea of the extent to which it supplements that of his predecessors. Nor has he given the external distribution of the plants enumerated. In these respects, therefore, it is less interesting than Watson's account. As a synonymic enumeration only is it superior; but it is a pity the author did not go a little further, even though he gave some of it at second-hand, because the older works are all comparatively rare.

However, we can only discuss what he has given us. British botanists will find the list easy to use, as the author has followed the *Genera Plantarum* and *Index Kewensis* as closely as possible. Typographical variations, asterisks, and other signs are employed to indicate the endemic and other elements. Dr. Trelease seems to have discovered no endemic plant previously altogether unknown; but he has been able to describe more fully several that were previously imperfectly known. The following is a list of the endemic plants:—*Cardamine caldeirarum*, *Cerastium azoricum*, *Hypericum foliosum*, *Vicia Denesiaana*, *Rubus Hochstetterorum*, *Sanicula azorica*, *Ammi Seubertianum*, *A. trifoliatum*, *Chærophyllum azoricum*, *Scabiosa nitens*, *Bellis azorica*, *Tolpis nobilis*, *Picris rigens*, *P. filii*, *Lactuca Watsoniana*, *Campanula Vidalii*, *Vaccinium cylindraceum*, *Erica azorica*, *Lysimachia azorica*, *Myosotis azorica*, *M. maritima*, *Veronica Dabneyi*, *Euphrasia grandiflora*, *Persea azorica*, *Euphorbia Stygiana*, *E. azorica*, *Habenaria micrantha*, *H. longibracteata*, *Luzula purpureo-splendens*, *Carex azorica*, *C. Vulcani*, *C. Hochstetteriana*, *Holcus rigidus*, *Deschampsia foliosa*, *Festuca petraea*, *Juniperus brevifolia*, *Isoetes azorica*, and *Selaginella azorica*.

A comparison of the foregoing list, with those of Seubert and Watson, reveals a reduction of the number of supposed endemic species as the result of further investigation. It differs very slightly from Watson's, the principal deviations being *Chærophyllum azoricum* and *Lactuca Watsoniana*, two of Watson's doubtful plants, described by Trelease as new species. The author does not mention that his identifications of these plants were verified for him at Kew by comparison with Watson's specimens.

The most surprising fact in the flora of the Azores is the smallness of the endemic element, which does not contain a single genus, and consists almost entirely of species belonging to genera, common not only to Europe, but also to the British islands. *Campanula Vidalii*, a shrubby species having rosettes of

leaves at the ends of the branches, is the only plant of an anomalous character. Dr. Trelease's fifty-five plates are devoted in part to the illustration of the endemic plants, and also, to some extent, of introduced plants, now very widely dispersed in warm and hot countries. One wonders why it should have been thought desirable to figure such plants as *Solanum pseudo-capsicum* and *Physalis peruviana*, especially as there is no reference to their illustrating any particular point or phenomenon. The half-a-dozen plates illustrating forms of *Agrostis Castellana* are of a more critical character. *W. Botting Hemsley*.

NEW OR NOTEWORTHY PLANTS.

CATTLEYA TRIANÆI, CHARDWAR VARIETY.

NOT among the hundreds of varieties of *Cattleya labiata* Trianæi have I observed any which, while exhibiting fine flowers, have offered so certain a means of identification as this one. The flower is 7 inches across, and the petals, slightly wavy at the edges, are 3 inches in width, and the sepals and petals are of a delicate lavender hue. The chief distinguishing feature lies in the colouring of the lip, the base of which, beneath the column, is of a rich purple hue, traversed by a clear network of white leaves, the purple colour shading off into a kind of glow as it nears the edges of the side lobes, giving the interior a pretty appearance. The disc is of chrome-yellow, the white lines of the base extending through it until it reaches the white band which divides the middle area from the bright purple colour of the front of the lip. This handsome variety was flowered by G. F. Moore, Esq., Chardwar, Bourton-on-the-Water.

CATTLEYA TRIANÆI, BROOME'S VARIETY.

This is a very beautiful variety, and entitled to rank with the best forms of *Cattleya labiata*. Its flowers are above ordinary size, the lip and petals broad and evenly arranged, so that, with the background of the sepals, the greater part of the circumference of the flower consists of showy segments that have great substance. It may be classed with the famous *C. T. Leeana*, excepting that the petals are nearly horizontal, and do not droop so much at the tips, and the lip is a much brighter colour, and petals and labellum are beautifully crimped at the edges. The sepals and petals are of a soft rosy-lilac hue, with silver-white mid-rib in the lower halves. The lip is on the outside rose-coloured, with veining of purple. Internally it is orange at the base, with some dark red lines, and the sides white, tinged with rose on the upper edges. The middle area has a divided yellow band, in front of which the colour is of a claret-crimson hue that merges into violet-purple; and changes to a lighter tint on approaching the crimped margin. The plant has flowered in the garden of Joseph Broome, Esq., Sunny Hill, Llandudno. Its owner considers it to be one of the best that he has flowered. *James O'Brien*.

CYCLAMENS.

It is extremely desirable in the interests of science (which means ultimately those of practice), that notes should be taken of the variations and "breaks" that occur in our cultivated plants. For this reason we add to the illustrations of variations of *Cyclamen* which we have already given an additional series of illustrations, taken from plants exhibited at the Royal Horticultural Society by Messrs. Sutton on January 11 last. Fig. 51 shows the nearest approximation to *C. latifolium* (persicum of gardens); and Fig. 52 shows a slight advance after cultivation; Figs. 53 to 55 show various forms of doubling, the doubling in this case being the result of the formation of an increased number of petals. The doubling of these flowers was the subject some years since of a paper in the *Transactions of the Linnean Society* by Dr. Masters, wherein the morphology of these flowers was discussed.

MARKET GARDENING.

(Continued from p. 118.)

CABBAGES.

SUCH varieties as Heartwell, Ellam's Early, &c., at Enfield Market, planted in September at the same distance as recommended for Cauliflowers, would command a wholesale price of 1s. 6d. per dozen following May—£68 0s. 6d., or putting the price 1s. per dozen, would give a sum of £45 7s. per acre. As soon as the first crop of Cabbage is cleared, ground should be planted with Lettuce, and *versé*, making for the two crops in the year at the higher rate £128 10s. 6d. per acre, and at the low prices £90 14s. 6d. And should Beet-seed be so pretty thickly in April, so as to admit of plants being available from the thinnings to transplant in an acre or more in rows at 1 foot apart, and 9 inches between rows, after the crop of Lettuce (following the autumn raised Cabbages) has been marketed, 1,593 dozen roots per acre will be secured, and which at 9d. per dozen will be £59 14s. 9d., thus giving a sum total of £188 5s. 3d. per acre for the three crops indicated one year.

Raising and forwarding young plants is a matter of great importance in connection with successful market and private gardening, inasmuch as earlier crops are consequently higher prices are obtained for the produce. In preference to the old-fashioned elevated and consequently exposed hotbeds, I shall recommend excavated pits—say 3 feet deep—if this can be safely done, 4½ feet wide, and long enough to admit of one or a series of four-light frames being placed over the hotbeds, leaving a clear space of solid ground 3 inches at sides and ends of frame or frames to rest on. Fill the pit thus made with leaves or long dung to within 3 inches of glass, trampling the litter &c., to make it firm before covering it with soil. This bed of soil should have a depth of 3 inches and be raked level, and on this sow the seeds of Cabbage, Cauliflower, Lettuce (Paris Green and Paris White Cos), and All-the-Year-Round and Favourite Cabbage varieties, and Brussels Sprouts, covering the seed lightly. Sufficient air should be given to insure sturdy growth as soon as the young plants appear. As soon as large enough to handle, prick them out 6 inches apart in a sunny aspect under glass preparatory to transplanting in the open later on. *H. W. W.*

CULTURE OF GARDENIAS.

The dropping of the flower-buds of *Gardenias*—or, at a later stage, of the expanded blooms—which my attention was directed by an answer to an enquiry in the issue of the *Gardeners' Chronicle* for Feb. 26, may in the absence of an obvious cause be attributed to inactivity of the roots, arising from the plant having had over-much water at the root, or water at a low temperature, and probably to excessive over-head syringing combined with a low temperature. Other causes of failure may be the excessive use of chemical manures, which are rarely needed when the cultivation is of the right kind. As the premature fall of the flower-buds is by no means uncommon, a few remarks to supplement what is stated at p. 132 may not be out of place. It is usually thought that *Gardenia radicans*, *G. Fortunei*, *G. florida* intermediate are capable of enduring any amount of heat with impunity, but this is an error common among gardeners who have no great deal of practical knowledge of the subject. Indeed, at the present time, I know an instance of a lot of *Gardenias* occupying a very warm part of a stove in close proximity to the hot-water pipes having become flowerless from this cause. The cause being known, means have been taken to remedy the evil by enclosing the hot-water pipes at that part in a chamber.

There are failures the cause of which are not thus clearly indicated, and then it is that sometimes the efforts at bettering are made in a wrong direction with the result of intensifying the trouble. Bees and worms, as stated in the editorial note, cause a most disastrous loss of plants. I have known houses of more than 100 feet long, 25 feet wide, become a prey to this foe, and after struggling with it for two or three years the cultivator has had to clear out an

FRINGED PETALS. (SEE P. 134.)

burn the lot. Not only is this a loss of plants, but it is also a loss that is felt probably during the whole period of occupancy.

Gardenias are much better bloomers when planted out in houses, large or small, devoted to them, growing only sufficient in pots to supply midwinter or very early blooms. Such plants may be grown in pots for two years or thereabouts, but if longer retained they are as a rule addicted to sickness that the best cultural methods will barely rectify. An important point in their culture in pots is rarely supplied long together, and unless periodical shifts are indulged in the plants are not sustained in a degree commensurate with their requirements. The item referred to is due to the fact that the plants are surface-rooters, a fact of importance, yet one that is often overlooked by gardeners. The Gardenia is, indeed, one of the few hard-wooded shrubs that produce surface-roots in such quantities as to render top-dressing an essential matter; and if this be afforded at the right season, and with discretion, the crop of flowers is sure to be abundant and good. Some gardeners prefer peat as the rooting medium, and I have seen instances where Gardenias have been planted out and surrounded by turves of the finest peat; but I have never observed in such plants the vigour remarked in plants grown in sandy loam, with slight additions of manure, such as leaf-soil, soot, or the like. In my neighbourhood there are perhaps several acres of Gardenias under glass, nearly the whole of which are planted out, in the ordinary staple, with or without manure as the case may require, and with perhaps the addition of some spent potting-bench soil, just to afford the plants a start. The vigour of such plants would surprise not a few gardeners, who only know Gardenias as pot plants. As a rule, the grower for market prefers pot plants of one or two years' growth for planting out, and the reason is that they are well provided with roots, and have a sort of ascendant framework of branches established as it were; but when, on the contrary, they are planted in a quite young state, and with plenty of space, the plants incline to trail about on the soil, to the detriment of the plant as well as the bloom, while the branches are also in the way when the beds are top-dressed. Plants that are grown rather closely together, as pot-plants usually are, become erect in habit, and these find most favour for planting out, for the after-growth alone will produce a spread of branches that completely cover the pathways in the houses. The fear generally with these when freshly planted out in new soil is that growth will become too rampant, and thereby impair the crop to follow. This is guarded against when top-dressing, and only the smallest amount of soil is afforded that will cover the roots. Originally planted in saucer-shaped holes sufficient to bury one-third of the ball of earth and roots, and the soil mounded up to them, the latter is added to from time to time, so that the mounds become a level bed. This may take two years to accomplish, by which time the plants are, perhaps, 4 feet high and broad. Plants four years planted become bushes of 6 feet or more in height, with branches so interwoven as to completely cover the beds, sometimes 6 feet to 8 feet wide, and form an almost impenetrable mass of dark green foliage. Established or old plants are given a small quantity of manure, artificial or other, occasionally, and usually some soot is added to the soil. Such plants are less liable to be infested by insect pests than those grown in pots. Few gardeners have the facilities for planting Gardenias in a house by themselves; but those having a front stage may plant them there in about 6 inches of soil. A few boards will make the bottom and sides complete, and the floriferousness of the plants will thereby be much increased.

Pot-grown plants need periodical surface-dressings. A half-inch layer of soil will be enough at a time, and as the roots will soon seize upon it, this will afford the best proof of its benefit. As a general rule, by artificial heat 65° to 75° is ample during growth, greater or less according to circumstances. In times of severe frost, a much lower temperature is often recorded with impunity. In these market establishments,

pruning is performed annually after flowering, and no stopping is indulged in unless it be that of a gross or forward shoot here and there. Bottom-heat is almost unknown, and the great bulk of plants luxuriating on the cool shallow beds of soil could scarcely be improved. J.

FOREIGN CORRESPONDENCE.

CANTUA DEPENDENS.

ONE of the most striking of the shrubs now in blossom in the garden at La Mortola is the Peruvian *Cantua buxifolia* or *dependens*. Its long tubular blossoms always begin flowering at the end of the branches, and not as represented by the drawing of Fitch in No. 4584 of the *Botanical Magazine*, which shows the flowers nearer the base of the branch more developed than those at the extremity. In the summer it gets rid of its leaves as a precaution against the heat and drought, though even so, it cannot go very long without being watered. In the autumn, however, after a little rain, it at once begins to throw out small pinnatifid leaves. As a rule, the stamens are bent on one side, rendering the radiate flower somewhat zygomorphic; but if, as occasionally happens, a bud is exactly perpendicular, the flower is then actually radiate. According to Delpino, the Italian plant-biologist, *Cantua buxifolia* is fertilised in its native country by humming-birds, as is often the case with tropical or sub-tropical flowers of this size. At La Mortola there are large numbers of bees, which serve to fertilise these plants; and it appears as though there were also a provision for self-fecundation. *Cantua dependens* may easily be propagated, both by cuttings and seeds, but it is a slow-growing shrub. A. Berger, *Cvrator, La Mortola, February 26, 1892.*

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Cattleya or *Intermediate-house*.—Plants of *C. amethystoglossa*, *C. chocoensis*, and *C. Walkeriana*, should be afforded a little more water at the root for a time, but when the blooms have fully expanded it may be withheld until the plants again commence to grow. *C. Walkeriana* (*C. dolosa*) produces its flower-spikes from the apex of deformed-like growths that spring from the bulbs last made, and as soon as these growths are seen suspend the plants where they will receive the maximum amount of light. The distinct-growing *C. Schilleriana* should now be placed in a similar position, and if any of the plants require fresh compost, or more rooting-space, it should be afforded them at once. A very thin layer of peat will suffice as a rooting medium. Keep the plants well supplied with water during growth. *C. labiata* *Warneri* should be afforded every encouragement until growth is completed, and the flowers appear. The best time to repot *C. Warneri* is when roots are to be seen issuing from the base of the new pseudo-bulbs. *C. Percivaliana*, having finished blooming may be kept rather dry at the root till growth recommences. *Dendrobium chrysanthum*, which comes from the hills of Nepaul, succeeds at the lightest end of this house. Although the plant may be growing vigorously, the grower must not be tempted to apply water very copiously, the effects of which would be that fewer roots would be made, and less growth. To obtain sound healthy growths and abundant flowers, keep the plant rather on the dry side until the roots are abundant, then the amount of water may be gradually increased. Plants of *Oncidium ampliatum* that have been at rest in this house, should be removed to a slightly warmer one and enough water afforded as will keep the roots moist. Wrap a piece of wool around the spikes to protect them from woodlice, cockroaches, and other insects. Vandas of the tricolor and *suavissection* grow thoroughly well at the cooler end of this house. At this season the lower foliage of these plants may be injured if exposed to the full glare of the sun, and the plants should be thinly shaded, independently of the other occupants. Strong healthy specimens will now be rooting freely, and any of the aerial roots that are long enough may be pegged or tied down so that they will root into sphagnum-moss, taking care not to crack or break them.

By enticing the roots down into the moss, plants grow with much vigour, and retain their leaves for a much longer period. The rare *Zygocarpum Perrenondii* also thrives admirably in the *Cattleya-house*. The plant is now growing freely, and as the flower-spikes push up in conjunction with the young breaks, it must not be disturbed at the roots until the flowers have faded. Afford water enough to keep the roots moist. Plants of *Angraecum falcatum* and *Aërides japonicum* that have been wintered in this house may now be removed to the warmest part of the cool-house. Both species deserve to be generally cultivated for the delicious fragrance of their flowers.

Orchid Pests.—Owing to the increase in warmth in the houses, small yellow thrips will multiply greatly, and these destructive insects must be kept under every means available. Before fumigating or ventilating the house the atmosphere should be made moist, and at the same time a moderately high temperature maintained. This will induce the insects to emerge from their concealment and be the more easily killed. If thrips are numerous, fumigate the house in the evening and the next morning, or on two consecutive evenings.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

The Flower-beds.—The spring-flowering plants, these, are very forward; Wallflowers, *Myosotis*, *Aubrietias*, *Daisies*, *Auriculas*, and many others, are already showing flower. The various species of *Hyacinths* and *Tulips*. The surface of the bed, if not carpeted with other plants, should be lightly pricked over with a small fork, in order to aerate and in that way assist growth. Those plants which are set out in regular lines, or where more than one sort is used in a bed, should be examined, and the side-growths pricked off where encroaching on neighbours, so as to maintain each variety separate, regards the colour of the flowers. Let the edgings of the beds be made thin and neat, and if the edgings are in use, these should be clipped as soon as danger from frost is past. Daffodils and *Priest's* roses in sheltered spots are already flowering freely, and the Winter *Aconites*, *Snowdrops*, *Pinks*, *Winkles*, and the *Violets*. In western and northern counties severe frosts and snowfalls have recently occurred, still everything indicates to the gardener that the busy season has arrived.

Sweet Peas.—Than these fragrant free-flowering annuals we have none superior, and no summer flower-border seems to be complete without them. The Sweet Pea has been greatly improved in form and colour during the last few years, and by no means more so than by Mr. Eckford, of Wern, Shropshire, whose varieties seem now to be acknowledged the best in the world. The varied hues of mixed colour in some varieties, the gorgeously and brilliantly coloured selfs of others, make Sweet Peas peculiarly adapted for cutting. It is to be hoped that the new dwarf Pink Cupid will be much freer flowering plant than the White Cupid, about which a fuss was made two or three seasons ago, and which appeared a good deal better in the photograph than the writer ever saw it in a garden. The best time for sowing seeds of Sweet Peas is towards the end of this month in the open ground, and the sowing is practically of the same nature as in the case of edible Peas, excepting that the seed should be sown even more thinly. If a position in the garden requires to be screened from view during the summer, or the plots of vegetables hidden from view, the Sweet Pea is the plant for the work. The soil should have been well manured and dug. It is advisable to coat the seed with red-lead previous to sowing it, as a defence against pheasants and mice. The rows should be provided with Pea-sticks when the plants are about 3 inches high, especially selected as regards neatness; and in very dry weather, copious applications of water should be made in order to maintain the plants in health; moreover, those Peas that are to furnish flowers should have all the seed-pods removed as soon as seen, or the flowering period will be shortened. If seed is required, a few rows should be set apart for seed bearing.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Young Vines.—Any of the eyes or cuttings, furnished with one bud each, when well rooted, may be shifted into 60's or 48's, accordingly as the shoots are strong or weak, the roots at the sides being

lightly freed from the soil before re-potting. Let the soil be well warmed, and the ball sunk so as to cover the young wood to the depth of a quarter of an inch with new soil, and the potting done with firmness. Remove them to a hot-bed having a bottom-heat of 80°, and top-heat of 60° to 65°, affording air whenever the weather permits. Support each stem with a stick, afford tepid-water, and shade from bright sunshine for a few days. The next shift may be into an 8-inch pot after re-potting the plants, and later wanted to fruit next year into an 11-inch one, always delaying to repot till the roots have permeated the soil and begun to coat the sides of the ball. Vines for forcing for fruit next year should be two years old, or at least they are generally the best for the purpose; and these should be grown in 8-inch pots the first season, taking care that the current season's growth is thoroughly ripened, and in the autumn the stems should be cut back to within two buds above the level of the soil, and kept cool and at rest during the winter. In early spring, these cut-backs may be started to grow in ainery, warm-house, or pit, where full sunlight can be afforded; and when shoots 4 to 5 inches long have been made, turn them out of the pots, carefully picking and shaking the soil from the roots, and repot them in clean pots of the same size as those they came out of, affording the pots drainage to the depth of 2 inches, and working the soil among the roots, and taking great care not to break off or injure the new shoots. After repotting, afford a moderate amount of warm water, and a few days afterwards remove all but the one strong shoot, should more than one of these have formed. The next shift, when well rooted, should be into 11-inch pots. Suitable soil for pot-Vines is one consisting of light turfy-loam, one peck of mortar-rubble broken small, and to each barrow-load of soil a 7-inch potful of bone-meal. Until the roots begin to permeate the soil, let water be sparingly afforded, and afterwards only when the soil is approaching dryness. Syringe once when fine, and as the season advances twice a day. The temperature should range from 60° to 65° at night, 70° on dull days, with a rise of 10° by sun-heat, and 5° beyond this after closing theinery. Afford ventilation on warm days when the warmth inside reaches 70°, and increase the amount gradually as the temperature continues to rise. Aim at obtaining large firm leaves, and canes that are short between the nodes or joints. Pot-vines may be fastened to upright sticks or to wires fixed to the roof, forming in the latter way pleasant shade for pot-plants growing beneath. Let the laterals and tendrils be frequently kept in check by pinching the first and removing the second, and secure the cane as it lengthens.

Vine Borders.—If any border in course of making is not finished so far as it is intended to extend it this year, the work should not be any further delayed if Vines raised last season from eyes are going to be planted in it. These Vines should now be placed in a warm house to encourage them to make a start, and when well started into growth let them be turned out of the pots, the soil shaken from the roots, and the latter laid out at full length, and covered with a nice mixture of fire soil to the depth of 4 inches. The distance of the Vines apart will depend upon the variety, 3½ feet for weak growers, and 5 feet for strong ones. Avoid planting close to the hot-water pipes, or the front wall of theinery—6 inches should be the nearest approach to either. On the renewal of growth in the plants, disbud the canes by degrees, and retain the best placed and strongest shoot to form the future Vine, which should be left as low down as the position will allow. The remainder of the treatment should correspond with that advised for potted Vines in general.

Late Vines.—Those which are intended to carry late crops should now be started, so that the fruit will have time to become quite ripe by the end of the month of September, after which date our sun has scarcely any effect on the maturing of the fruit. The inside border, if but slightly moist, should receive a thorough application of tepid water. Let the Vines be syringed once or more often daily, and generally carry out previous directions in regard to the Vine.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

Cauliflower Plants under Protection.—Those plants which have been protected by cold frames may be transplanted during mild weather, choosing a warm border and well-enriched soil. First, let drills be drawn 3 inches deep in which to plant them at a

distance of 18 inches apart, and 2 feet will be found sufficient space between the rows. After planting, place Spruce twigs thinly round the plants, as a protection against frost and wind. Let the tops of hand-lights in which Cauliflower plants are growing be lifted off in fine weather, in fact ventilating them at all times when there is no frost. Remove weeds and stir the soil, affording water if the soil is dry. Cauliflowers raised from seeds sown last month will be large enough to prick out on to a gentle hotbed or in boxes placed in a warm pit or greenhouse, to bring them forward and fit to plant out in the beginning of April, keeping them close to the glass meanwhile. Sow seeds in gentle warmth, and also on a south border, of Early London, Early Forcing, Magnum Bonum, and Walcheren varieties.

Leeks.—Seed of the Musselburgh and other varieties may be sown for the main supply in shallow drills, or broadcast in beds, treating them similarly to the Onion, only the seeds may be sown more thickly, transplanting the plants during May and June. The plants raised from seeds sown under glass in January will require to be pricked off, but not to be unduly hurried by artificial warmth; rather aim at keeping them sturdy by careful ventilation, and by affording them a place on a shelf near the roof. The remains of last year's crop should be dug up and laid in close together in deep trenches in a shady place for future use.

Tomatos.—The plants that are in bearing will be improved and strengthened by top-dressing them with rich soil mixed with some artificial manure, guano, &c., affording water soon afterwards so as to carry it to the roots. Plants now in bloom or setting will be benefited by a dryer and slightly more artificial warmth in cloudy weather, which will admit of more air being afforded. The pollen should be detached and distributed by means of a soft brush. A sowing of seed may now be made of out-door varieties, such as Conqueror, Large Red, Early Ruby, Frogmore Selected, Sutton's Magnum Bonum, and Maincrop.

General Remarks.—Wheel manure on vacant plots, and without loss of time get the land dug after the manure is spread; or if this cannot be performed, put the manure into good-sized heaps, under the protection of a covering of soil; and do not let most of its good properties be driven off by wind, rain, and sunshine, as would occur if left exposed. Walks may be re-laid, and Box and other edgings laid or made good.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Coleus.—Plants which have been grown in a light position in a warm house will now yield a good supply of cuttings, which may be placed either singly in the smallest sort of flower-pots, or to the number of four or five round the side of a 5-inch pot; of the two methods the former is preferable, because, on being repotted the plant is not checked much, whereas, in the other case, some of the roots are sure to be damaged. The soil should be light and sandy, and newly-potted plants plunged in gentle bottom-heat in a frame, &c., after affording them water. Shade them from the sun when very bright till air may be freely afforded. Where there is no demand for large specimens, plants not advisable to keep any longer may be used for affording cuttings, and then thrown away. If young plants be grown on freely they soon become useful in decorative arrangements.

Nepenthes.—Any plants that have become leggy should be cut down to within 6 inches of the base, the stems being cut into lengths of two leaves to each, inserted in sphagnum-moss and sand, and plunged in a brisk moist heat to form roots, which they soon do. Any which have made four or five leaves, and are not required for stock, may be pinched at the tip in order to get them to break and form pitchers, for if the plants are allowed to run away, they soon become incapable of producing them. Basketed plants that need more space, may be placed, without any disturbance whatever, inside a new basket, filling in and around it with lumps of peat, charcoal, and sphagnum-moss. If Nepenthes are infested with thrips, use Richards' XL All, which at once destroys the perfect insects, but not the eggs.

Conservatory and Greenhouse Climbers will now need attention. Tacsonias, Coleus, Passifloras, Bignonias, and others of a similar habit of growth, should have the growths well thinned out, cutting them back close to the main stem; those of a close-growing, bushy nature, such as Stauntonia latifolia, &c., should have all weakly growths cut away, as if these

be allowed to form dense masses, they fail to flower satisfactorily. Swainsonia galegifolia alba is an extremely useful climber to grow where cut flowers are in demand; and for covering bare places quickly, Steptosolen Jamesoni will also be found to answer this purpose admirably, and it flowers freely, making a fine display. Advantage should be taken after the pruning is done to thoroughly cleanse the structure, and afterwards to afford the climbers themselves a thorough syringing with some suitable kind of insecticide, Tobacco-water, &c. Examine the tubs, pots, and borders in which the climbers are growing, and where necessary replace any spent or soured soil, giving particular attention to the drainage in all cases; and in cases of bad drainage, replanting in new soil may be found desirable. Plant-borders in the conservatory may be rendered attractive by dibbling-in cuttings of Selaginella denticulata, after having planted spare plants of Pteris serrulata, P. s. vars., Adiantums, Asparagus plumosus nanus, Ophiopogon Jaburan variegatum, &c.

THE HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Grape Vines.—Some varieties of the Grape-vine succeed on south walls in warm districts in extra warm summers, the fruit being of better quality than the ordinary imported Almeiria and other Spanish wine Grapes. If more attention were devoted to these Grapes in the matter of culture, our out-of-doors Grapes would be much improved, and in seasons when the Grapes do not thoroughly ripen they could still be made into a palatable wine by using a certain proportion of cane-sugar with the must. The Vines should now be pruned, leaving the strongest, best ripened shoots of last season's growth as fruit carriers. Sometimes young shoots of 8 feet and upwards in length can be laid in, and old canes will sometimes have to be removed to make room for such, and if these are nailed in, in a wavy line instead of a straight one, the buds will break regularly; the weak shoots of last year's growth must be spurred back to one or two buds, and these will in their turn furnish bearing-wood another year. Strong young rods of Vines may sometimes be trained between the fruit trees on a wall or along the upper part of a wall, and thus fill up spaces which would be otherwise unutilised.

Mildew is the greatest foe to the Grape-vine out-of-doors, and if it be allowed to extend unchecked, good Grapes cannot be obtained. If the Vines have been attacked with mildew the previous year, the cause of attack should be sought for, and remedial measures taken forthwith. Mildew is traceable to poverty of the soil, excessive moisture, or extreme dryness at the root, cool, and consequently wet summers; in short, anything which causes a check to the growth of the Vine, and with proper attention most of those may be remedied. The resting spores of the mildew fungus should be destroyed, i.e., after pruning, take the Vines from the wall, and with a paint-brush thoroughly wash the wood with Gishurst Compound Soap, using it at the rate of 4 oz. dissolved in 1 gallon of rain-water, the wall being also washed with the same. When the Vines are again fastened to the wall, remove the crust of soil with a steel fork to the depth of 4 inches, and if it be infertile afford a liberal dressing of farmyard-manure, and replace the old soil with turfy loam that has been stacked up for six months. The best varieties of dessert Grapes for outdoor cultivation are Esperione, black, and Royal Muscadine, white; these give good-sized berries if properly thinned, and ripen much earlier than Black Hamburgh or Foster's Seedling. Miller's Black, if thinned, is not to be despised.

Peaches and Apricots.—The trees, when in bloom, should have some moveable kind of protection afforded them, than which nothing is better or more lasting than thick canvas roller-blinds. Failing these, doubled fish-netting may be used, and it is not necessary to remove this, but it may remain till the fruit is safe. If bloom be scanty, a camel-hair pencil should be passed over the flowers at intervals of three days, choosing the middle hour of the day for this operation.

HARDY PRIMROSES.—The seeds should be sown thinly. An Auricula-fancier of my acquaintance when he sows his seeds from the finest fertilised flowers, in order to sow them thinly on his dark soil, dusts a little fine and dry-powdered whiting over them, and then shaking them in it they become white, and in this way he is able to distribute the seeds evenly over the surface. R. D.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR MARCH.

TUESDAY,	MARCH 8	Royal Hort. Soc. Com.
MONDAY,	MARCH 14	Annual Meet. United Hort. Ben. and Prov. Inst. at Caledonian Hotel, at 8 P.M.
TUESDAY,	MARCH 15	Cornwall Daffodil and Spring Flower Show at Truro (two days).
THURSDAY,	MARCH 17	Linnean Society Meet.
TUESDAY,	MARCH 22	Royal Hort. Soc. Coms.
WEDNESDAY,	MARCH 23	Torquay Gard. Assoc. Spring Sh.
SATURDAY,	MARCH 26	Royal Bot. Soc. Gen. Meet.
TUESDAY,	MARCH 29	Spring Show of Shropshire Hort. Society. Exhibition of Royal Hort. Soc. of Southampton (two days).
WEDNESDAY,	MARCH 30	Royal Bot. Soc. Spring Show at Regent's Park.

SALES FOR THE ENSUING WEEK.

MONDAY,	MARCH 7	Hardy Perennials, Iris, Roses, Greenhouse Plants, &c., at Protheroe & Morris' Rooms.
TUESDAY,	MARCH 8	Orchids, at Protheroe & Morris' Rooms.
WEDNESDAY,	MARCH 9	Lilies, Roses, Gladioli, Carnations, &c., at Protheroe & Morris' Rooms. Roses, Fruit Trees, Shrubs, Bulbs, Plants, &c., at Stevens' Rooms.
THURSDAY,	MARCH 10	Border Plants, Shrubs, Lilliums, &c., at Stevens' Rooms.
FRIDAY,	MARCH 11	Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—41° 7°.

ACTUAL TEMPERATURES:—

LONDON.—March 2 (6 P.M.): Max., 48°; Min., 37°.

PROVINCES.—March 2 (6 P.M.): Max., 46°, Scilly; Min., 37°, Aberdeen.

The National OUR anticipation in last week's Chrysanthemum issue, that the annual meeting of the National Chrysanthemum Society would be unusually interesting, was more than realised. The spirited though orderly discussion that took place on Monday evening last showed conclusively that there are serious defects in the management of the Society's affairs, and from the remarks of several of the members of the committees, it seems more difficult to apportion the responsibility than it should be. The Society has been surprisingly successful in many ways. Each year it has become numerically stronger, and its income has increased. Dealing with one flower only, and that almost entirely from the exhibition standpoint, the importance the Society has attained is the more remarkable. But there has been a disposition on the part of the committees to travel both faster and farther afield, and the expenses have increased at such a rate as to more than equal the income. It was on this score that criticism was offered at Monday's

meeting, the speakers having little difficulty in proving, that although the statement of accounts submitted by the committee showed a balance of nearly £40 to the good, there had, practically, been a loss on the year's work. To meet the present liabilities, without touching the reserve fund, the management had treated as assets many items that, if negotiable at all, would realise next to nothing. We assume the general committee should take responsibility for the drafting of the accounts, yet the Secretary declared that they had been submitted to the committee, that they had been passed without criticism, and after this had taken place, some members of the committee denounced the accounts at the annual meeting, and the treasurer stated that he had only been a treasurer in name!

The report read by the secretary was couched in most re-assuring terms. "Its work (the Society's) during the past twelve months was carried on with energy and success; its resources are as great as ever, its supporters more numerous; it is financially sound, and its prestige knows no diminution." Unfortunately this is not quite correct: the Society has undoubtedly lost influence, and for some time past its reputation has not been exactly that which should characterise so strong a Society.

The report concluded by announcing that through ill-health the honorary treasurer had decided to resign his position. The receipts for the year had been £1123 9s. 10d., the principal items of which were £304 13s. from subscriptions, £300 from the Royal Aquarium Company, £121 4s. 6d. from the sale of medals, &c., to affiliated societies; £115 14s. from entrance fees and rent of space at exhibitions, £75 1s. affiliation fees, and £81 2s. from advertisements in schedules and catalogue. On the expenditure side, as much as £532 16s. was spent upon prizes and medals, and £18 18s. judges' fees.

The adoption of the Report having been formally moved by Mr. T. W. SANDERS from the chair, and duly seconded by Mr. H. J. JONES, Mr. STARLING explained his position in regard to the treasurership, and expressed decided disapproval of the balance-sheet. He had been a treasurer in name only, and though all monies received by the Society had not passed through his hands he maintained that they should have done so. He had not the necessary time to devote to the duties of the office, but regretted that he was not leaving things in a more satisfactory condition, declaring that the Society still owed about £90, and that the assets were not equal to meeting this.

Then followed a criticism by Mr. GEO. GORDON, who said that there was insufficient control exercised over the items of expenditure, which were ever growing. In 1891 the cost of luncheons, &c., was £15, it is now £24; and in the same year the deficit upon the annual dinner was £15, and it is now £18. This expenditure was more, even in 1891, than it should have been, and the annual dinner should be made to pay its way. Show expenses at the Royal Aquarium in 1891 were £12, they are now £32. The Society had voted medals, illuminated addresses, &c., to worthy persons no doubt, but the Society should pay its way before disbursing such honours. A lesson might be taken from the Royal Horticultural Society, who, when awarding last year sixty medals in celebration of a certain event, had omitted to award a single medal to any member of the Council, although several of its members were exceptionally deserving of the honour. The

National Chrysanthemum Society "should spread its tail, for every ass to bray at, or to kick." Mr. GORDON referred to the expenditure of the coming year, stating that the committee had proposed to award £610 the four shows, or including special prizes £714, only £124 less than in the Jubilee year when the income was greatly augmented. Mr. GORDON concluded by moving the following amendment to the report:—"That the report and financial statement be referred to the committee, with instructions to prepare a proper balance-sheet; to prepare an estimate of income and expenditure for 1898, and to report on the advisability of a reduction in the number of exhibitions, or in the prize-money, during the current year, and to submit the same to an adjourned annual meeting to be held that night three weeks at six o'clock."

The amendment was seconded by Mr. J. W. MOORMAN, who declared that whilst the balance-sheet showed a sum in hand of £38 odd, the society owed £85 11s. 6d. In supporting the amendment, Mr. BEVAN maintained that all debts must be paid and vouchers obtained before the accounts could be handed over to a new treasurer, and he might say that the gentleman it was proposed to nominate to this position would refuse to stand before this had been done.

Then came an explanation from the secretary who stated that the financial position was due entirely to the action of the Schedule Revision Committee, who were increasing yearly the value of the awards offered for competition. He had stated that during the year there had been 114 new members added, but this was largely discounted by the fact that 85 of the old members had not paid their subscriptions. If the policy of the Schedule Revision Committee was not modified, the Society would be landed in bankruptcy.

Mr. W. H. LEES, a member of the above committee, rejoined by stating that Mr. DEAN himself had urged upon the committee the necessity of making some of the increases now the subject of complaint.

The question of auditing was opened, and Mr. MOORMAN complained that at the time and place the work was to have been done, neither auditors, books, nor secretary could be found. This was satisfactorily explained, however, and was due to the proprietors of Anderson's Hotel having given insufficient notice to the secretary that they were unable to provide a room as arranged. Mr. H. J. JONES testified to having witnessed for two hours the progress of the audit at the Aquarium tavern, and he was surprised at the thoroughness with which every detail and voucher was examined.

The amendment having been formally put from the chair, and Messrs. ADDISON and HARMAN PAYNE appointed tellers, the result was 82 ayes and 6 noes. Put subsequently as a substantive motion, the amendment was carried unanimously.

On the motion of Mr. HOLMELEY, it was decided that the amended accounts should be printed and sent to members seven days before the adjourned meeting is to take place. Mr. WELLS asked why a form should not accompany these prints, in order that members living at a distance might vote by proxy; but the Chairman explained that one of the rules declared that voting must be by ballot, or by show of hands, and it was not permissible to alter rules unless previous notice be given.

The members afterwards separated, and the remaining items upon the agenda will be con-

COLOURS PINK AND WHITE: SIZE 15 FEET ACROSS, 10 FEET THROUGH, AND 6 FEET HIGH; NUMBER OF FLOWERS 812. (SEE P. 139.)

sidered at the adjourned meeting. On that occasion it is very important that all members who can should be present, so that the amended accounts may be given the consideration it is desirable that they should receive, and that the election of committees, treasurer, secretary, and auditors be made by a meeting that will command respect from every member of the Society. There should be no fault-finding unless a purpose is to be served thereby; no exposure for mere exposure's sake, nor any hesitation in enquiring into the details of expenditure or management—if the object be reform. Surely there are a few business-like and influential members, free from personal dislikes and prejudices, who are capable of leading the debate in such a manner as to effect what is most desirable, without creating such disorganisation as may partially paralyse the society for a twelvemonth.

There is one point in the amendment carried the other evening with which we are in the fullest accord, namely, the instruction to the committee to consider the advisability of making a reduction in the number of shows annually held. The September exhibition, for instance, as we have stated again and again, has never been other than a discredit to the Society, and it has no influence whatever in popularising the Chrysanthemum. In our opinion, too, the Society would do well to confine itself to its special business. It should not attempt to form a general exhibition, and allot medals and awards which only tend to belittle similar awards made elsewhere. It is true that the same judges exercise their functions in other societies, but that does not detract from the fact that no special society can hope to win reputation when it steps out of its own special and, in this case, well defined work. It would be inconsistent however, with the maintenance of reputation, were the Society to repudiate a contract already made by its accredited committee, with the Royal Aquarium Company, or other parties, and for this reason it may be found inexpedient to take action in this matter that will affect the current year, though the sooner the Society disavows its connection with the Aquarium the better.

Flax in Ireland.

SOME time since we drew attention to the fact that the Supply Association of Belfast had been

lending the services of a Dutch cultivator, or expert, for the benefit of Irish cultivators; but now we learn that Flax-growing is decreasing in the land where it ought most to be prized. It yields a fair profit, and Belfast is the largest linen-producing centre in the world, some of the manufacturers being among the most enterprising spirits of the time. For the facts: in 1880 there were 157,534 acres under cultivation; in 1893 this had fallen to 67,487; but a fillip was given to the trade by a rise in prices, a widening demand, and other causes, and the record of acreage for 1894 was 101,081; 1895 found the number of acres reduced to 95,293; 72,235 in the year following; and last year the record was reduced to 60,000 acres, very much less than half the acreage under Flax in 1880. All this in spite of the efforts of the Flax Supply Association to improve the conditions of culture, the improvement of the seed, and other minor matters. True, Flax is a starving crop, and a disagreeable one to handle, but surely this is not the sole deterrent, the crop, as we are assured, being a paying one; and one seems forced to the conclusion that the cause of decay must be looked for in the cultivators.

GIGANTIC CHRYSANTHEMUM.—Mr. FOUKUBA, the Director of the Imperial Gardens at Tokio, sends us through Mr. G. SCHNEIDER, a photograph, of which a reproduction is given in our supplementary illustration (fig. 56). The specimen is 5 metres across (about 5½ yards), 3·30 m. (10 feet through), and 2·10 m. (6 feet, 6 inches) high. The number of flowers is 812, each flower being on the average 8¼ inches in diameter. The variety is an unnamed one, of a deep rose colour, striped with white.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Fruit and Floral Committees will be held on Tuesday, March 8, in the Drill Hall, James Street, Westminster, from 1 to 4 P.M. At 3 o'clock, the Rev. Professor GEO. HENSLOW, M.A., V.M.H., will lecture on some of the plants exhibited.

HORTICULTURAL CLUB.—The usual monthly dinner and conversation will take place on Tuesday, the 8th inst., at 6 P.M. The subject for discussion will be "Cinchona in India," to be opened by Mr. J. F. GAMMIE, formerly Deputy-Superintendent of the Government of Bengal Cinchona Department.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, March 7, when a paper will be read by Mr. W. IRVINE (late Bengal Civil Service), entitled "Land Survey and Valuation in Northern India." The chair will be taken at 8 o'clock. Members hoping to join the party at Manchester on April 20 and 21 are requested to fill in and return, at their convenience, the fly-leaf attached to the circular letter forwarded to them on the 7th ult.

THE SAN JOSÉ SCALE.—In reply to a question put in the House of Commons, the President of the Board of Agriculture, Mr. LONG, said that the subject was being carefully investigated, and that any assistance which could be given to fruit-growers would be rendered when requisite. In the meantime, we have not heard of the introduction of the scale into this country. The samples sent to us, being Oranges and Lemons, with the very common mussel-scale.

JUGLANS RUBRA.—At the January meeting of the Vienna Horticultural Society, Herr OTTO PFEIFER exhibited a fruit of *Juglans rubra*, with a red-skinned kernel. The fruit attracted much attention, and a variety of opinions were expressed by those present as to its growth and hardiness in the severe winter climate of Austria. At present it is a rarity.

MAGNOLIAS AS FORCED PLANTS.—We read in the *Wiener Illustrierte Garten Zeitung* of a plant of *Magnolia Soulangeana* having been shown at a meeting of the Vienna Horticultural Society held on January 10, 1898. The forcing of Magnolias is not quite a novelty. The blooms of *M. Soulangeana* are tulip-like, and outwardly of a purple-red hue, and with a pleasant fragrance. As the editor remarks, the variety is not so well adapted for the bouquetists' art as the smaller, snow-white, softly fragrant *M. stellata*, so that the latter would be a much more suitable plant as well as a more floriferous one.

JAPANESE STRAWBERRY-RASPBERRY.—We have always mistrusted the statement that hybridisation of the Strawberry with the Raspberry had been effected in this country, and now we have, it is alleged, a similar hybrid from Japan, and a figure is given in the *Wiener Illustrierte Garten Zeitung* for February, made from a drawing by Herr J. C. SCHMIDT, who remarks that the plant can be raised from seed, and is of easy culture. It appears that the plant has a height of 18 to 27 inches, possesses pretty foliage, and numerous white blossoms, resembling those of the Dog-rose, and it may be cultivated as a fruit-bush or an ornamental shrub. The fruit is like a Strawberry in shape, &c., and in flavour it is halfway between that kind of fruit and a Raspberry. The annual growth dies down in the winter, growing with increased vigour the next season.

THE KEW GUILD.—Members of this excellent institution who were not present at the annual meeting held on the 24th ult., may be interested to know that the event again attracted a number

of "past Kewites" to the familiar lecture-room, where they met most of the present staff, including three ladies. The genial president of the guild, Mr. GEO. NICHOLSON, took the chair, and was supported by a few members of the committee. The report, as read by the secretary, Mr. WATSON, was generally satisfactory, though a proposed alteration in one of the rules gave rise to some discussion. This alteration was desirable in order to admit to the guild botanists and others who have been employed at Kew, but who are not covered by the word "gardener." The discussion was occasioned owing to the indefiniteness of the words used in the alteration, many of those present holding that all persons employed at Kew in any capacity might claim that they filled a "responsible position." The progress made is encouraging, but it is nevertheless felt that a large percentage of gardeners who were once at Kew are still unattached to the guild, in the sense that they do not obtain the society's *Journal*. The present addresses of some also are still unknown, and it is hoped that all old "Kewites" who have not yet communicated with the guild's secretary will do so, and that eventually the *Journal* will find its way to every person entitled to membership. When one of the "present" students had been elected as a representative upon the committee, the rest of the committeemen and the auditors were re-elected. It would be advantageous to the guild if a greater number of members would make a point of attending the annual meetings.

A NURSERYMAN JUSTICE OF THE PEACE.—Mr. GEORGE PAUL, one of the County Councillors for the Cheshunt and Waltham Cross divisions, has been placed on the Commission of Peace for the County of Herts.

FASCIATED BROCCOLI.—Messrs. WATKINS & SIMPSON send us a curious example of their hardy Christmas Purple Broccoli, in which the stem has flattened out, so as to form a mass singularly like the Cockscomb celona.

CŒLOGYNE CRISTATA.—The popularity in gardens of this fine Orchid is unmistakably attested by the photographs we frequently receive from our correspondents who have successfully cultivated it. Some of these have been reproduced in our pages, but for which fact we should gladly place before our readers illustrations of two that have just reached us. One is from Mr. F. TUNBRIDGE, Brooklands Gardens, Broomfield, Chelmsford, and it represents a magnificent plant in a 10-inch pot which, our correspondent informs us, has produced seventy spikes, bearing five or six blossoms each. The plant opened its first flowers on the first of January, and still bears several spikes of perfect blooms. The second is one from Mr. GEO. TAYLOR, The Gardens, Broxmouth Park, Dunbar, and illustrates a house of well-grown plants in full flower. They both bear conclusive evidence that the species is very skilfully cultivated by our correspondents.

HIGHGATE AND DISTRICT CHRYSANTHEMUM SOCIETY.—The exhibition of this society is to be held at the Holloway Hall on Nov. 8, 9, and 10 next. Several classes will be added to last year's schedule, making up the total to ninety classes. It was unanimously decided by the committee that the society should discontinue its affiliation with the National Chrysanthemum Society, and award its own certificates and medals. It was also agreed that certificates should be awarded to new varieties of Chrysanthemums if of sufficient merit.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.—We learn that there will be as usual two shows held this season, and a sum of £638 awarded in prizes, i.e., £272 for the Spring Show, to be held on April 6 and 7; and £366 for the Autumn Show on September 14 and 15. Such a Society, affording as it does opportunities of viewing the triumphs in flower, fruit, and vegetable culture, and striving to afford great encouragement to all classes of cultivators, deserves very liberal support from those who

are fond of horticulture. The annual subscription is one guinea and half-a-guinea, and the Society gives to its subscribers admission-tickets to their shows to the full value of their subscriptions.

BARREL STRAWBERRY CULTURE.—A recent number of *American Gardening* has an illustration showing a method of cultivation which is new to us. From the illustration, it seems that the barrel is set on end, perforated at regular intervals in the sides, and filled with soil. The plants, we suppose, are inserted in the holes in the side, establish themselves in the soil, and thrive so well that Mr. OHMER, the grower, had last season sixty such barrels, which gave on the average half a bushel of Strawberries to the barrel. Some such device might be tried here, and the use of Jadoo-fibre suggests itself for private if not for commercial use.

SHEEP POISONING.—From the *Strathearn Herald* it appears that some twenty sheep died recently, or had to be killed, in consequence of having eaten the leaves of Rhododendrons in a wood to which they had gained access through a broken fence.

SIR JOSEPH BANKS.—The portrait of Sir JOSEPH BANKS, in the possession of the Royal Horticultural Society, had from circumstances been allowed to acquire a disreputable appearance from the accumulation through many years of smoke and fog. Lately, by the action of the library committee and the trustees of the Lindley Library, this fine portrait has, so to speak, been brought to life again and protected by a sheet of glass. It was painted by T. PHILLIPS, R.A., and there hangs in the same room an engraving taken from the picture. Now that the veil of dirt has been removed, the portrait is seen to be one of great excellence. We may add that there are portraits of the great naturalist in the Royal Society's rooms, also by Phillips, and in the library of the Linnean Society. The portrait of Dr. LINDLEY, of course, of more recent date, has been treated in the same way as the Banksian portrait, and it may be hoped that the Fellows will be so pleased with the work of the joint committee that they will furnish the means for effecting several other desirable operations of the same kind in the Library.

HARDY FLOWERS.—Mr. WARE, of Hale Farm Nurseries, Tottenham, sends us *Narcissus bicolor* Victoria (new) similar to *bicolor grandis*, but differing in being much earlier; it is a first-class plant for forcing, and a most prolific variety. *Colchicum libanoticum*, with lilac flowers produced with its leaves, is one of the very best of spring-flowering Colchicums. *Anemone blanda atrocerulea* is one of the hardiest of winter-flowering plants; it has been in flower at Tottenham since January. *Orchis Robertiana* is also quite hardy, and invariably flowers this time of the year in sheltered spots. *Iris stylosa* and the two varieties *stylosa alba* and *speciosa*, also *stylosa Elisabethæ*, have been in flower the whole of the winter. *Eranthis cilicicus* differs from the ordinary winter Aconite in that it flowers very much later, and the flowers are of a deeper yellow. *Muscari azureus*, closely allied to the Grape Hyacinth, has been in flower here since the beginning of January, and is one of the best of spring-flowering plants. *Galanthus Ikarie* is probably the best of the green-leaved Snowdrops; the flower is large, and it is very free and a most vigorous growing species, and the leaves are unusually broad, and not plicated.

PUBLICATIONS RECEIVED.—*Park and Outside Art Association*, 1st Report, Louisville, Kentucky. This chronicles the objects of the Society, and the papers read at the meeting called to consider the value of public parks and pleasure-grounds, and the best means of starting and supporting them in Kentucky.—*Twenty-first Annual Report of the Connecticut Agricultural Experiment Station*. The contents of this publication include papers on Mildew, on Lima Beans, Prevention of Leaf-blight and Leaf-spot of Celery, Cause and Prevention of a Fungous Disease of the Apple, Investigations of a Disease of Carnations, and Literature on Fungous Diseases.—*U. S. Department of Agriculture, Farmers' Bulletin*, No. 68.—*The Black Rot of the Cabbage*, by E. F. SMITH, and Division of

Entomology.—*The Gipsy Moth in America*, L. O. HOWARD.—*Agricultural Gazette of New South Wales*, December, 1897.—*The West Australian Settlers' Guide and Farmers' Handbook*, Part V., devoted to questions relating to Soils and Manures.—*The Newcastle Daily Chronicle Edition of the British Almanac and Year-Book for 1898*, contains not merely much local information, but a wonderful amount of general and miscellaneous matter.—*Der Gärtner und Blumenhändler*, Berlin, February 2, 1898.—*Journal de la Société Nationale d'Horticulture de France*, Janvier, 1898.

KEW NOTES.

CALADENIA ALBA.—The genus *Caladenia* occupies a similar position among Australian plants, that *Disa* has among the plants of South Africa. There are about thirty species, all terrestrial, with small underground tubers, annual grass-like leaves, and erect slender scapes bearing one or a few flowers, in which the sepals and petals are sometimes produced into long tails. None of the species have hitherto attracted the attention of horticulturists, although some of them are showy. A pan of *C. alba* is now in flower in the Orchid-house at Kew. Each plant has a solitary linear leaf 6 inches long, a thin green erect hairy scape 8 inches long, and a white flower 1 inch in diameter, with narrow lanceolate sepals and petals, the dorsal sepal curved over the column, the other segments pointing downwards; lip half-an-inch long, recurved, with two rows of hairs forming a callus. Benthams makes this a variety of *C. carnea*, the type of which has pink flowers.

PALISOTA MACLANDLI.

A large plant of this is now in flower in the Nepenthes-house at Kew. It was first described by Professor Maxime Cornu in the *Bulletin de la Société Botanique de France*, 1896, p. 30, plants having been raised and flowered in the Jardin des Plantes, Paris, from seeds received from the Ivory Coast, W. Africa, in 1894. It has branching stems a yard high, 1 inch in diameter, and glossy-green leaves, usually in whorls of three or four, each a foot long, 3 inches wide, lanceolate, petiolate, covered with soft hairs, the margins of the petiole having dark brown hairs an inch long. The flowers are borne on erect panicles a foot long, and they are very numerous, about half an inch across, white and purple. There does not appear to be any specific difference between this plant and the specimens of *P. thyrsoidea* in the Kew Herbarium. Professor Cornu, however, says it differs from that species in having narrower leaves with longer petioles and woodier stems. It is a handsome plant for large tropical houses. A figure of it has been prepared for the *Botanical Magazine*.

DRACENA THALIOIDES.

A large example of this West African species is now flowering freely in the Palm-house at Kew. It has numerous stems, the tallest being 5 feet high, and the sub-erect, distichously-arranged leaves are from 2 to 3 feet long, the upper half of which is a bright green lanceolate blade, 3 inches long, the lower half being a narrow-channelled grey-green petiole, with a broad sheathing base. As a foliage plant it has its attractions, but it is much more ornamental when in flower, its racemes being 2 feet long, branched, and crowded with long, slender, tubular flowers, $1\frac{1}{2}$ inch long, the segments linear, $\frac{3}{4}$ inch long, and recurved, their colour being white, tinged with purple; they are powerfully fragrant. The Kew plant flowers freely every year. It was introduced into cultivation about thirty-five years ago, but only came into prominent notice four years ago, when it was figured in the *Gardeners' Chronicle*, vol. xv. 1894, p. 137.

ALPINE AND HERBACEOUS

Plants are flowering early and numerous in the Rock Garden and the Alpine-house at Kew. In the former the *Chionodoxas*, both *Luciliæ* and *Sardensis*, are represented by thousands, painting the slopes blue in some places with *Diffidils*, *Hellebores*, and even *Snowdrops* occurring abundantly and in variety. Such rarities as *Shortia*, *Soldanella*, *Iris orchioidea*,

and *Tecophylea*, are in flower in sheltered nooks. In the Alpine-house, which is rapidly filling with plants of interest, the following may be seen in bloom: *Fritillaria aurea*, *Anemone vernalis*, white *Chionodoxa*, *Soldanella pyrolæfolia*, *Romulea Linariifolia*, *Corydalis Kolpakowskiana*, *C. rutæfolia*, and some good examples of the best of the blue *Primroses*. The *Saxifragas* and *Muscari* will soon be at their best. W. W.

BOOK NOTICE.

A FLOWER-HUNTER IN QUEENSLAND AND NEW ZEALAND. By Mrs. Rowan. (London: John Murray.)

SOME of our readers may have had the opportunity of seeing the very beautiful presentments of Australian plants which were shown in London not long since, and they will equally welcome the present volume. Others to whom the attainments of the authoress may not be familiar may be assured that in this little volume they have the record of a series of excursions in Northern Queensland and in New Zealand, which, for variety, interest, adventurousness, and personal danger, can have hardly been exceeded, even by the most intrepid of travellers. The descriptions are highly picturesque and animated, and they deal with districts little known to the ordinary traveller, at least, so far as Queensland is concerned.

The aim and object, and the precise dates at which these wonderful excursions were made, are not very clearly made known. There is, in fact, a want of cohesion and continuity in the records, which are at times rather puzzling. The preface leads one to infer that the authoress is herself an Australian, though it is not so stated. At any rate, her desire to complete her collection of floral-paintings carried her "into other colonies, Queensland, and some of the remotest parts of the great continent of Australia." Incidentally, we learn that the authoress has resided, at least temporarily, in New South Wales, and in Western Australia. The work is divided into two sections, the first devoted to Northern Queensland, the second to New Zealand.

It is the first section that is most novel to the ordinary reader. The lady seems to have travelled unattended. She commences her narrative at Rockhampton, and proceeds thence to Torres Straits and the Louisiade Archipelago. Her journey is mostly by sea, but at intervals she lands and penetrates far into the interior in her search for flowers, and there meets with a constant series of adventures, such as one would expect to find in the pages of a highly flavoured romance. Deserts and jungles, natives of the most debased type, cannibalism, storms, tropical heat, snakes, Mango swamps, fever, mines, caves, forest-fires, runaway-horses, mosquitos, rough travelling of every description, even to travelling on a cow-catcher—nothing daunts this adventurous lady. Her descriptive powers are much beyond the average, so that it is easy to picture the scenes. Unfortunately, the author's knowledge of natural history is not equal to her zeal, so that it is not possible in all cases to know of what plants she is speaking. The specimens hitherto unknown were, we are told, "named by the late Sir Frederick Müller"—meaning, of course, Baron Sir Ferdinand von Mueller. The error is in itself trifling, but it does not increase the confidence of the botanical reader.

It is interesting to note that the Cocoa-nut fringes the coast line off Murray Island, that tree being scarcely recognized as an Australian native. At Somerset, Cape York, she remarks that, "excepting three trees, there is absolutely not one plant I have ever seen before; and at a little distance from the sea, and sheltered from the wind, the jungle is even more beautiful than on the Johnstone River, which I thought nothing could surpass. There is a magnificent Palm-tree beside the Jardine's house, which is not known anywhere else except in one spot a few miles away; and the native Fig-trees, now covered with fruit, are magnificent-looking, with wonderful colouring,

their young leaves of a delicate pink, shaded off to a vivid green in the older, while they are as large as most of our English trees. Another tree, with clusters of blossoms, like a Jessamine, is a mass of starry blossoms, and the whole air is redolent with its scent." It is rather provoking to read such descriptions and not to know what they refer to.

Our notice has run to such a length, that we must forego reference to the section relating to New Zealand. Moreover, the wonders of those islands are more familiar to the reader than the remote jungles and tropical forests of Queensland. A map and several pretty illustrations adorn the work, the greatest charm of which, however, consists in the vigorous prose in which the authoress describes her adventures. It is needless to say, we recommend everyone interested in Australian travel to possess themselves of the book.

less be the best horticultural manure in the market—for we have been told so again and again, and what is more, asked to say so sometimes. In addition, there were bones broken to various sizes, bone-dust, Peruvian guano, nor must we omit to mention the particular manure known as Smyth's Fertiliser, and described by Mr. Smyth as "a true gardener's friend." We saw peat and peat, loam and loam, of different characteristics, and intended for plants of diverse requirements. The materials requisite for the making of a good rooting medium for Orchids appear to be given much consideration. Sticks in many sizes for the support of plants, Bamboo-canes, wooden labels in a dozen sizes; tying materials, such as tarred string and raffia, an article known by so many names, and which is derived from the Palm Raffia ruffia, and probably another species. But in tying we require knives, and hence there were pruning and budding-

DUMELOW'S SEEDLING APPLE (SYN. WELLINGTON AND NORMAN- TON WONDER).

THIS, in my estimation, is the best winter cooking Apple that we possess. I have tried lately upwards of twenty good varieties by cooking them in a different manner, which, to my mind, is the best test, as many varieties which might take the prize in the raw state at a show are very inferior when cooked. Dumelow's Seedling (fig. 57) retains its sharp flavour to the last, and does not shrink much on being cooked, and is in use from the beginning of November to the end of March and later, and it is therefore an Apple that should be more largely grown than is the case at present. *Wm. W.*

HOME CORRESPONDENCE.

VICTORIA MEDAL IN HORTICULTURE.—An important engagement prevented my staying sufficiently long at the annual meeting, or I intended to put this question on this subject. Was the medal struck to commemorate the Diamond Jubilee of the Queen, or was it to commemorate Her Majesty's long reign? Is the number of medallists rigidly and irrevocably fixed at sixty? If struck to commemorate the Jubilee, then sixty would be a most appropriate number; but if to commemorate the long and glorious reign, why not create, so to speak, one medallist for every year, or, if desirable, every year or part of a year of Her Majesty's reign. This, I think, would be much more of a commemorative nature than the present limited sixty. If such an idea be practicable, I am sure horticulturists in general, and Fellows of the Royal Horticultural Society in particular, would warmly welcome the name of Sir Trevor Lawrence as number sixty-one. *Robt. Fife, Orpington.* [We have before suggested that the President and Secretary of the Society should be *ex officio* members of the order, and we were led to understand that they would have been proposed as such at the annual meeting. As matters stand at present, the medallists constitute a body without a head. *ED.*]

ROYAL HORTICULTURAL SOCIETY'S AWARDS.—Doubtless much might be said for the argument to leave well alone in matters of awards at the Drill Hall meetings. But judgment should lean towards deprecating the cheapening of awards by their too-bountiful bestowal. Although my suggestion is not perhaps of any great merit, yet if it turn the scale as against letting alone, my purpose will have been gained. The advantage supplied by the very full descriptions that appear in all the horticultural papers of the various subjects submitted at these Drill Hall meetings is no slight advantage for the trade, and personally I am inclined to think they are capital advertisements to be acted upon by those who are by distance precluded from frequent attendance. I should pay no overwhelming attention to honoured subjects alone. Awards should be curtailed. *H. H. R., Forest Hill.*

THE GARDENERS' BENEVOLENT.—I was truly disappointed by the result of the gardeners' election, having voted, as also my employer, for a deserving subscriber of a dozen years, only to find a non-subscriber at the top of the list—this seems wrong and discouraging. I often ask my brother gardeners to subscribe, and have got many to do so, but the answer they give is often that non-subscribers seem to stand the best chance, and the list of non-subscribers that succeeded at this last election gives colour to this opinion. We thought that the giving a number of votes to each candidate who had been a subscriber, according to the number of years he had subscribed, would have helped him, but this seems to have failed at the last election. *Old Subscriber.*

LADANUM AND LAUDANUM.—Whilst on the subject of Ladanum, and the ancient trade in it, there is a Hebrew word "Lot" used twice in Genesis, and there only, which those learned in Hebrew tell us is identical with the eastern name of Ladanum (see Kitto's *Bible Dictionary* under Lot). The passages are Gen. xxxvii., 25, where Lot was amongst the wares which the Ishmaelites, to whom Joseph was sold, were taking from Gilead to Egypt. Again, Gen. xliii., 11, Lot was one of the presents Joseph's brethren took to him in Egypt. In both these passages, Lot is in the authorised version translated

FIG. 57.—DUMELOW'S SEEDLING APPLE.

SUNDRIES.

ONLY a little less in importance than the acquisition of first-class seeds, does the gardener regard this question of Sundries. And if one reflects for a moment what the term may, and usually does, include, it becomes obvious that without some of them at least, the most skilful gardener, though he possessed the best soil and unsurpassed seeds, would be unable to obtain much success. Thus it is interesting to visit a "horticultural sundriesman," and since Mr. H. G. Smyth has removed from premises in the Coal Yard, Drury Lane, to a new establishment in Clark's Mews, High Street, Bloomsbury, we called upon him, with a view to seeing his new establishment, and maintaining our intimacy with these gardeners' aids to gardening. Proceeding at once to the basement, there was a quantity of bags and packages, representing Clay's Fertiliser, Thompson's Vine and Plant Manure, and specialties of other makers, each of which must doubt-

knives, *sécateurs*, scissors, and gloves for the protection of the hands during pruning. Syringes, too, in variety, and sprayers, steel trowels, sieves, garden pencils, thermometers, wood-wool for packing, scavenger and other descriptions of brooms and brushes, and watering-cans. Teak-baskets for Orchids constitute quite a feature in the sundries business, and Mr. Smyth has a Teak cylinder in which vertical ribs are fastened together at top and bottom by a strong copper-wire. Small pieces about 1 inch in length keep the ribs apart at the top, but not at the bottom, so that the cylinder is pot-shaped. Glass house shadings made and fitted to order are sold, which differ considerably in the amount of light they admit to the house, and one specially adapted to particular kinds of plants may readily be chosen. But we must forbear to particularise more, and may add only, that in the Diamond Jubilee year, when honours of various sorts were fashionable, Mr. Smyth was appointed "Horticultural Sundriesman to Her Majesty the Queen."

Myrrh, which is generally represented by Mor in Hebrew. Again, as Professor Henslow points out on page 130, the Hebrew word Roth, translated "gall" in certain passages, was probably opium, which was well known to the ancient Jews. In Mark xv., 23. The "wine mingled with myrrh," called in Matthew "wine mingled with gall," is thought to have been wine mixed with opium; hence we have in the authorised English version "myrrh" used both for Ladanum and for opium. The coincidence is probably accidental, but in view of the origin of the use of Ladanum or Laudanum for opium, is worth noting. *C. Wolley Dod, Edge Hall, Malpas, Feb. 27.*

FREESIAS.—Mr. Wallace seems to have had some good results abroad in the cultivation of Freesias, and I and others who are interested in this favourite flower would be glad of information in regard to the locality the plants are grown, the kind of soil, and to know if the land was prepared in any particular manner for the reception of the bulbs. Many of us doubtless wish that we could obtain from seven to ten laterals, and 136 flowers from one bulb. *W. L., Road Ashton Gardens.*

FISH-MANURE.—If Mr. C. Blake, whose enquiry I read in the *Gardeners' Chronicle* last week about fish-refuse, would put the fish-refuse into a large square hole, in alternate layers of fish and earth—or, better still, clay, he would at the end of six or nine months have a manure superior to any guano he could buy. I have experience of this. *C. Bellwood, Coombe Royal Market Gardens, Kingston.*

THE WEATHER AND THE GARDEN.—The welcome change from extreme mildness to dry, sharp frost has been opportune in checking the untimely opening of the flowers of the Apricot, Pear, and Plum; but the colder winds and sharp frosts which we have experienced this week, namely, 12° on Monday, and 11° on Tuesday and Thursday nights, have given a wholesome check, strengthening the blossoms in some degree at least, and rendering them less susceptible to injury by frost later on. The prospects in this neighbourhood of a good fruit year are at the present moment very favourable, the trees of the Pear, Apple, Plum, and Cherry being literally covered with fruit-buds. The majority of the buds on Pears and Plums have already burst their covering. Raspberries, Currants, and Gooseberries are also in a very forward state. Strawberries, owing, probably, to the cold nature of the soil, remain at present in their ordinary resting condition. *Geo. Woodgate, Rolleston Hall Gardens, Burton-on-Trent.*

CYTISUS PROLIFERUS.—This plant does not seem to be known to our English nurserymen, for I fail to find it in any catalogue I possess. It is a very useful subject in the month of January, the flowers appearing on plants in a cool-house at that time. The flowers are whitish in colour, and unlike most other members of this family are produced in axillary umbels along the sides of the preceding year's growth; these umbels contain each six or seven flowers, and are convenient in size for wiring into bouquets. They are sweet scented, but not so strongly as are those of *C. racemosus*; and unfortunately it is not so easily raised from cuttings as the latter variety, as I have failed to strike one, although they have been tried under various conditions; but if budded on *C. racemosus* it grows vigorously the following season. According to the *Dictionary of Gardening* it was introduced from Teneriffe in 1779. I hope to try its hardiness in a sheltered position eventually, but hitherto have had only one plant large enough for the purpose. *W. H. Divers, Belvoir Castle Gardens.*

POTATOS IN AMERICA.—Referring to note on above in your issue of September 11 last, where it is stated, "It is noteworthy in the respect that English Potatoes are a failure on the farms of the States. Repeated attempts at their cultivation have been made, but sooner or later—generally in a couple of years or so—the variety has dwindled away, and the 'crop' does not equal the seed in weight." In 1890 I sent some seed of my Early White Beauty to Robt. Ballard, Esq., President of Common Council, Syracuse, N.Y. The following year he wrote me a glowing account of the crop and quality produced. On reading the note quoted above, I thought it would be interesting to ascertain what had been the fate of the White Beauty—if it had dwindled away in the eight years' cultivation; and I wrote to Mr. Ballard asking how it had fared with him. I have just received reply from that gentleman, dated the 17th ult. He says:—"I and my son are still planting your Early White Beauty from the same stock as you

sent us eight years ago. We still think the flavour and quality superior to any other variety we get here. The tubers do not grow so large as some other kinds, but we get a good average crop, which last season was quite equal to that we grew the first year we had them." *F. Webber.*

ROYAL GEORGE APPLES, ETC.—There are sure to be many rivals to all varieties that are of special goodness, but whether the original tree of Royal George Apple is one of them I am unable to say, still it may be a satisfaction to know that it was once a popular variety in this locality, where there are some very aged trees locally known by that name; indeed, the locality seems to have been famous for its Apples, and some of the varieties grown were suitable to the soil and climate, and useful. The variety known by the old inhabitants as Royal George, is a robust, compact-growing tree, but as far as I have seen it, is a variety that never crops very heavily. The fruit is flat, smooth, and not very large; handsome, streaked with red on the sunny side. As all the trees here were very old ones, the fruit was never above medium size, and always much grub-eaten, consequently it fell from the tree before fully grown. Cliff's Pippin is another useful local Apple, a large free-bearing good-cooking variety, not unlike Tower of Glamis; the tree is robust, a free bearer, and a fairly good keeper. Swane's Pippin is another old local variety of compact growth, the fruit being not unlike a badly coloured Mère de Ménage, being green, with a dense bloom upon it a capital cooking variety, with flesh as white as that of any Apple that I know of. Then we have Taylor's Pippin, which is identical with Newton Wonder. The original tree of this is now supposed to be growing at Stanton, near Melbourne; it is supposed to be a seedling from Normanton Wonder. The garden in which it grows has been in the occupation of the family of Taylor for many generations. As all of the trees of Royal George that I have met with are very aged, they were probably advanced in years before the variety was named Royal George. Whether the variety recorded by your esteemed correspondent, Mr. Pownall, as growing at East Bridgeford is the same I am unable to say, but there is another locality near Nottingham famous for Apples, namely, Dale Abbey, where some fine trees of Blenheim Orange, Maltster, and the small but free-bearing Eve Apple, so much esteemed in the local markets, may still be standing. *J. H. Goodacre, Elvaston.*

RAINFALL, ETC., FOR 1897.

ACCORDING to the rain-gauge of Sir J. B. Lawes at Rothamsted, Hertfordshire, which was constructed forty-four years ago, we find that the rainfall for the year 1897, recently ended, amounted to a trifle over 27 inches, which is about 1½ inch below the average for this district of the last forty years. The following table shows the rainfall for each month of the year, with the average of each month extending over a period of forty years; and 1897 more or less than the average quantity.

ROTHAMSTED EXPERIMENTS.
Rainfall for 1897, and Average for Forty Years.

Months.	1897.	Average Forty Years.	1897 More (+) or less (—) than Average.
	Inches.	Inches.	Inches.
January ...	1·93	2·45	—0·52
February ...	2·92	1·74	+1·18
March ...	4·20	1·73	+2·47
April ...	1·91	1·97	—0·06
May ...	1·72	2·33	—0·61
June ...	2·73	2·41	+0·32
July ...	0·47	2·73	—2·26
August ...	3·24	2·60	+0·64
September ...	2·44	2·55	—0·11
October ...	0·96	3·19	—2·23
November ...	1·05	2·77	—1·72
December ...	3·50	2·17	+1·33
Total ...	27·07	28·64	—1·57

The rainfall is thus seen to be very unequally distributed. There were seven months with a deficiency, including the usual growing period of April and May; and after but little more than an average fall in June, there was again a deficiency in

July of 2½ inches. The harvest month—August shows a slight rise above the average amount. The total sunshine recorded for the year 1897, according to the Rothamsted measurements was 1,568 hours whilst at the Royal Observatory, Greenwich, it was 1,542 hours out of a possible 4,454 hours. The four months, viz., April, May, June, and August the recorded sunshine at Greenwich was more than at Rothamsted, whilst in each of the other months the record at Greenwich was less than at Rothamsted, the most marked month being September, which shows a difference of twenty-three hours in favour of Rothamsted. During the summer months of May, June, July, and August, the bright sunshine registered at Rothamsted was 878 hours; at Greenwich it was 901 hours; whilst at Bradford, according to the record of Mr. John Clayton given in the *Gardeners' Chronicle* of December 25, p. 449, it was only 780 hours, which was stated to be unusually high for that neighbourhood. Sunshine is no doubt an important factor with vegetation, especially in promoting maturation, and I observe here, as Mr. Clayton does at Bradford that the formation of fruit-buds is very conspicuous and there is every promise of an abundant fruit-harvest. *J. J. Willis, Harpenden.*

THE ROSARY.

PRUNING THE ROSES.

THIS is such an important part of Rose-growing, that there needs no excuse for referring to it at this date. Far more harm can be done among our outdoor Roses by an injudicious use of the knife than by almost any other course, and if the knife is not used aright, little benefit follows from having well-grown matured wood. Hybrid Perpetuals vary in growth, from the rods of 10 feet, as in Margaret Haywood, to 2 feet in E. Y. Teas and Duchess of Bedford. There are also several very moderate growers that are of very little value after the maiden stage is passed, viz., Cointet, Xavier Olibo, Horace Vernet, and some few others. This wide difference in the strength and length of the shoots made in one season divides the Hybrid Perpetuals naturally into three sections or groups.

Taking the very vigorous growers first. It is one of the greatest mistakes to curtail the long, ripened growths of the previous summer more than can be avoided, as these shoots afford a quantity of blossom of good quality, and it would be of no assistance to the plant to remove or greatly shorten these. I do not purpose saying how many buds should be left upon a shoot, nor at just what length either lateral or vigorous shoots should be, as that would be obviously misleading, because if we look at a few varieties we find such great diversity in the numbers of buds upon the shoots. As a general rule to follow, let laterals be cut back for two-thirds of their length, whether weak or strong, and save as much as may be convenient of the ripened long growths, which invariably flower more evenly throughout their length when pegged down, or secured by some means in a slanting position.

Strong growers that are not of extraordinary vigour afford great diversity, for while those of Ulrich Brunner, and Général Jacqueminot may not make a really strong shoot, they frequently do so, as do also Pride of Waltham, Suzanne M. Rodocanachi, and other smooth-wooded varieties. And in the case of these and others like them, if a strong shoot is made from the base, it will be well to bend it downwards rather than to shorten it or leave it as it is. Most rosarians require a quantity of blooms of good form and substance, and a shapely plant. As soon as the first crop of flowers is secured from these long rods, the cultivator should prune them back and restore balance of the head. The ordinary growth of the shoots of this section of the Rose may be shortened to one-third or one-sixth of their length, according to strength, always bearing in mind that the stronger the growth, the less is the need to prune hard. The direction of the terminal bud, and thinning the centres of the plants as far as may be done without

sacrificing good wood, are matters that are known to most rosarians, and need only to be mentioned.

Other Roses although possessing a robust, strong habit, as Baroness Rothschild and Merveille de Lyon, need much closer pruning, for the plants grow upright and are sturdy, so that unless pruned closely their shoots get so crowded that but little of their beauty is seen. Let the centres of such be thinned out thoroughly, and let all the shortened shoots have the terminal bud point outwards. Tea-scented and Noisette Roses may safely be treated upon much the same lines, and among them is a large number which invariably make a quantity of healthy laterals. The two or three eyes left after a flower has been cut will push out and flower again, or leave valuable wood for the following year. Marie Van Houtte, Anna Olivier, Dr. Grill, G. Nabonnand, Francesca Kruger, and Ernest Metz are half-a-dozen well-known examples. Here I would prune back each sound and well-ripened lateral to within 3 or 4 inches of its base if a promising bud exists there, and thin out the centre severely, and so do away with the risk of having a lot of flowerless shoots.

The weaker growers, such as Perle des Jardins, Madame Cusin, and Sunset should have almost the whole of their really strong and mature wood retained; as should likewise Souvenir d'Elise Vardon, Cleopatra, Comtesse de Nadaillac. I am aware that in this paragraph I may seem somewhat contradicting my opening notes, but I have found it best to leave the majority of sound eyes upon these; as also on plants of Ma Capucine. Quite in contrast to the last are those of such extraordinary growth as Rêve d'Or, William Allen Richardson, Crimson Rambler, and Maréchal Niel. These should be treated according to the methods advised for the extra vigorous hybrid perpetuals. The shoots may be pegged down, or trained on walls and fences. It may be remarked that most of these are grown upon walls having a warm aspect; and Crimson Rambler is the better for being placed in a partially shaded and cool position. This class may also be grown upon low walls and fences if cut back rather hard, and the long rods encouraged after flowering. In the early part of the year, train these in cordon form, or even as edgings to lawns and large flower-borders. Another method is to obtain a few long growths, and after these have flowered, and the laterals are matured, spur them back half way, when, if the wood is fairly ripe, it will flower without the need of maiden rods each year, although it is advisable to preserve a new rod occasionally.

The shoots of the Ayrshire Evergreen and other very rampant climbers may be left at full length, or slightly shortened, if the position demands it, as may the rugosa and Hybrid Sweet Briar. Bank-sian Roses need a little thinning out of the old wood, but the ripe shoots of last year's growth should be left intact, together with much of the new wood upon any part of the plant, especially that arising from the bottom. The weather has been favourable to the tender Roses, and there is promise of an abundant show of flowers.

Moses, Provence and Gallica Roses, may be pruned rather hard, but the Persian and Austrian Briers only need thinning-out, and last year's long shoot to be left intact.

So far as standards are concerned, we should prune each class upon the same lines, when if long rods are left, they will hang over in a pleasing manner. I have not mentioned the Hybrid Teas, but they may be pruned upon similar lines to the above. Some H. T.'s are more like the H. P.'s than the Teas, and *vice versa*, and let each be pruned according to the class it most nearly resembles. A. P.

SOCIETIES.

LINNEAN SOCIETY OF LONDON.

FEBRUARY 17.—MR. F. N. WILLIAMS, F.L.S., read a paper on *Arenaria*, one of the larger genera of Caryophyllaceae, which now includes a considerable number of species. *Alsine* and others, usually included as sections of the genus,

he thought should be regarded as distinct genera; *Alsine* and *Arenaria* being distinguished by the same cardinal character which separates *Lychnis* from *Silene*. The genus under revision includes species (of which 168 are enumerated) distributed chiefly throughout the north temperate zone, though in the New World a few occur in South America. A few species which extend toward the tropics occur at considerable elevations on mountain-ranges, reaching, for instance, 19,000 feet in the Himalayas of W. Tibet. In this revision, for the formation of primary groups, the two associated characters relied on are the number of teeth formed by dehiscence of the ripe capsule, and the structure of the disk. An examination of several series of specimens, especially of those of the better known forms growing *in situ* shows these two characters to be fairly constant, and suitable for the definition of primary groups, although in habit and aspect species of *Alsine* are not readily distinguished from those of *Arenaria*. The author's descriptions are confined to species recognised during the last fifty years (from 1848 to 1897 inclusive), the others being cited in their proper place by name and references.

CHELMSFORD HORTICULTURAL.

FEBRUARY 17.—The adjourned annual meeting of the Chelmsford Horticultural Society was held at the Vestry Hall on Thursday evening, Mr. W. W. DUFFIELD presiding.

Mr. G. T. Weeks, the hon. secretary, presented the financial statement, which showed receipts £219 5s. 8d. (including £104 18s. 6d. and £87 14s. 8d. gate-money, and £57 19s. grants), and an adverse balance of £87 4s. 4d., of which £29 11s. 6d. were outstanding subscriptions. There was a loss of £12 14s. 10d. on the year.

WINCHESTER GARDENERS' ASSOCIATION.

FEBRUARY 22.—The usual monthly meeting was held on the above date, when, by favour of the Hampshire County Council, Mr. GARNER, of Cadlands Park, Fawley, Southampton, gave a very instructive and practical lecture on "Fruit Culture under Glass," which was greatly appreciated by the members present.

The subject is a too lengthy one to be embodied in one necessarily abbreviated lecture, but as full justice was done as the time permitted, and it formed the last of the present series of meetings.

EXETER AND DISTRICT GARDENERS' ASSOCIATION.

FEBRUARY 24.—At the usual fortnightly meeting of the members of the Exeter and District Gardeners' Association, held at the Exeter Guildhall on the above date, Mr. T. H. SCADE, Poltimore Gardens, in the chair, Mr. W. R. Baker, gr. to Lady Duckworth, of Knightleys, Exeter, read a paper on "The Cultivation of the Potato." There was a capital attendance considering the inclemency of the weather. In the course of his remarks, Mr. Baker advocated an occasional change of sets, and the adoption of the more modern varieties, many of the fine Potatoes of twenty or thirty years ago having "run out," so that they could not compare with the best of our present day varieties, as for instance, Early Puritan, Windsor Castle, The Garton, Up-to-Date and Boston Q.Q., Satisfaction, &c. As to growing tubers for exhibition purposes, he said it was an easy matter to obtain large handsome tubers if the following method was followed. Let the sets be of middling size, and lay them in shallow wooden trays in a cool, dry place, with the sprouting end upwards; removing all shoots but the strongest, and permitting no other to remain on the plant after it begins to grow above-ground, for even when the tuber is thus early disbudbed some latent buds will push forth weakly shoots. In earthing-up none of the foliage should be covered with the soil. The best kind of land for Potato culture is a friable well-drained loam, and, if artificial manure be used, kainit was the best. In a sandy light soil he used plenty of cow-stall (oxen) manure; and if the soil was heavy, stable manure and fresh lime. A remedy for the scab of soil which affects Potatoes in some kinds was a liberal application of fresh soot. About thirty dishes of the leading varieties of Potatoes were shown.

The lecturer drew the attention of his hearers to the excellent effects that followed the spraying of the foliage of the Potato with the Bordeaux Mixture in June and August. An instructive discussion followed the reading of the paper.

LANCASTER HORTICULTURAL.

FEBRUARY 26.—The twenty-second annual meeting was held on the above date, Colonel FOSTER (President) in the chair. Although last year's show was most excellent in character, the public support was so scant, that there was a loss on the year of nearly £33, the gate-receipts, which amounted to £128 5s. 9d. in 1888, and averaged £90 for the last eight years, being only £15 last year. A Cycle Trade

Exhibition was tried in conjunction with the last exhibition, and the committee are so discouraged, that they recommend no exhibition be held this year. The Hon. Secretary, Mr. J. Hatch, announced, however, they might have a cottagers' show, as the number of allotments and interest in cottage gardening are increasing, of which late shows offered evidence. Colonel Foster, M.P., was re-elected President.

CHESTER PAXTON.

FEBRUARY 26.—At the usual bi-monthly meeting, held at the Grosvenor Museum on the above date, Mr. A. T. GILLANDERS, High Leigh, delivered a lecture on "Forest Entomology," to the members, who were present in goodly numbers. The lecturer dealt in a comprehensive manner with the life-histories of the gall-mites, saw-flies, beetles, and other insects, often so injurious to forest trees; and gave valuable hints as to the best means of preventing these pests from doing damage. The lecture was copiously illustrated with lantern-slides, at the close of which Mr. Gillanders was accorded a hearty vote of thanks.

ROYAL GARDENERS' ORPHAN FUND.

FEBRUARY 25.—A meeting of the executive committee took place on the above date at the Horticultural Club, when Mr. William Marshall was unanimously elected chairman for the present year. The following special receipts were announced:—Mr. M. Todd, Edinburgh, £30 10s.; Mr. H. J. Jones, Lewisham, box in Chrysanthemum show-house, £14 3s.; Mr. J. Gammie, Chiswick, £5 5s.; Mr. H. Eckford, Wem, £2; Mr. B. Marks, Hardwick, Bury St. Edmunds (box), 10s.; Messrs. Jones & Son, Shrewsbury (box), 9s. 3d.; Mr. J. Hamilton, Byrkley, Burton-on-Trent (box), 8s.; Hook Cottage Garden Society, 6s. 6d.; Mr. J. Pearce, Belmont, Lee, 12s. 5d.

The secretary made a report as to the result of the recent election, and laid upon the table the usual documents, signed by the guardian of the child, in most cases the mother filling that capacity, and properly attested. A sub-committee was appointed to arrange the details of the annual dinner. A cordial vote of thanks was passed to the chairman for presiding.

TREES AND SHRUBS.

PRUNUS AMYGDALUS VAR. PERSICOIDES.

It is curious that so little should be known of the merits of this variety of the common Almond. Rarely, if ever, is it catalogued even by the leading nurserymen. It is, nevertheless, according to my experience, one of the most valuable of all the varieties of the Almond, for it flowers, as a rule, at least two or three weeks in advance of any other variety. It has been partially in flower at Kew since the beginning of February, and quite fully out since about the 10th or 12th, far surpassing either of the forms of *Prunus Davidiana* in beauty. The flowers are, of course, much larger than those of *P. Davidiana* (although not so large as the best forms of the common Almond), and the tints are richer than those of even the variety of David's Peach, known as *rubra*. The name *persicoides* is quite an old one, and is mentioned by Du Hamel in his *Treatise on Trees and Shrubs*, published early in the present century. The variety is worth bringing into notice as a beautiful hardy tree, following close on the popular *Prunus Davidiana* in time of flowering, and thus the second earliest of the great *Prunus* tribe. It is no accidental freak, for at Kew it has shown the same character during the last four or five years to my knowledge. It is planted in quite exposed positions.

NUTTALLIA CERASIFORMIS.

Whilst the flowers of this Californian shrub have no bright colour to recommend them, they appear each spring with such unfailing regularity and profusion, and so much in advance of the great bulk of spring flowering trees and shrubs, that the species deserves a place in every garden. Its flowers are very gracefully borne on short pendent racemes, and the calyx is green, the corolla white. The mode of flowering strongly suggests a *Ribes*, a resemblance borne out also by the habit of the shrub, which forms a wide, dense thicket of erect branches, suckering freely from the base. It is, however, a Rosaceous plant, and is nearly allied to *Prunus* (in some catalogues it is called *Prunus californica*). It is perfectly hardy, and thrives well in any fairly rich, moist soil; but in spite of this, and the fact that it was introduced fifty

years ago, it is a comparatively rare shrub. There is an excellent figure of it in the *Gardeners' Chronicle*, April 18, 1896, p. 489, and several bushes may now be seen laden with bloom in the grounds at Kew.

ERICA LUSITANICA (E. OODONODES).

In the London district, unfortunately, this beautiful Heath is not absolutely hardy. Winters like the one just past do not of course, affect it in the least, but severe ones are apt to cut it back more or less, and when it has to encounter a time like that of the January and February of three years ago, it is killed outright. It is, nevertheless, well worth growing, and especially so, of course, in the milder parts of the country. It comes into flower in February, and keeps in beauty for a couple of months at the least. It is one of the tallest Heaths, and Lindley (*Botanical Register*, t. 1698) describes a specimen at Maresfield in Sussex, as a bush 10 to 12 feet high. The flowers are white, and although small, are remarkably abundant, every one of last year's growths being thickly crowded with the tiny white bells. The flowers have a slightly Vanilla-like odour. The species is a native of Spain and Portugal, and ought to find a place in all gardens where peat-loving shrubs thrive, and especially where the earliest-flowering ones are desired. W. J. B.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named: and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending February 26, is furnished from the Meteorological Office:—

"The weather during this period was generally cold and changeable. Showers of cold rain, sleet, and hail were very prevalent during the earlier half of the week, and large quantities of sleet and snow fell over our southern and south-western counties, accompanied in some places by thunder and lightning. By Friday, however, the conditions had changed, and milder weather became prevalent, with rather heavy rain in the west and north, and slighter amount elsewhere.

"The temperature was below the mean, the deficit ranging from 2° in the 'Channel Islands' to 5° in 'England, W.' The highest of the maxima were recorded towards the end of the period, and ranged from 51° in some parts of the southern and south-western districts, to 47° in 'Scotland, N. and W.' The lowest of the minima varied greatly in different parts of the kingdom. In 'Scotland, E.' (at Braemar, on the 24th), the sheltered thermometer fell to 3° F., in 'England, N.W.' (at Manchester, on the 21st), to 17°, and in 'England, S.W.' and 'Scotland, W.' (at Culmington and Glenlee, on the 24th), to 18°. In the other parts of the kingdom they varied from 19° in 'England, E.' and the 'Midland Counties,' to 25° in 'Ireland, N.' and to 35° in the 'Channel Islands.'

"The rainfall somewhat exceeded the mean over 'Scotland, E.,' 'England, S.,' 'S.W.,' and the 'Channel Islands,' and 'Ireland,' and just equalled it in 'Scotland, N.' In all other districts the fall was less than the normal, especially in 'England, E.' and the 'Midland Counties.'

"The bright sunshine was much above the mean generally. The percentage of the possible duration ranged from 55 in 'England, N.W.' and 53 in 'England, E.' to 34 in 'England, S.,' and to 27 in 'Scotland, N.'"

CULTURAL MEMORANDA.

MARANTAS.

ALL the species delight, during the growing season, in a high temperature and an abundance of atmospheric moisture. They also require shade from hot sunshine, or the leaves are liable to become rusty in appearance. Placed between larger growing plants in the stove they succeed well enough, and most of the species may be readily increased by division of the crowns in early spring.

The beginning of March is the best time to repot the plants, at the same time dividing those that require it. If large specimen plants are not desired for any purpose, it is best to divide the crowns annually, by which system the individual leaves as they advance into growth are provided with sufficient space for development. This is a decided advantage in the case of dwarf-growing varieties as *M. (Calathea) Massangeana*. A compost of equal parts fibrous mellow-loam, peat, and decayed cow-manure, broken roughly with the hand, adding a liberal quantity of silver-sand, and a few nodules of charcoal and pot-sherds, I have found most suitable, and the whole should be well incorporated. The pots used should be absolutely clean, and the drainage perfect in every respect, for when growing freely, the plants must be given copious supplies of water. Syringe the plants thoroughly overhead with rain-water twice a day in bright weather, and keep the foliage clean by occasionally sponging it with soapy-water. When the plants have partially filled the pots with roots, they may be given weekly applications of liquid-manure, which, however, should not be permitted to touch the foliage. From the commencement of October until March, a dryer atmosphere will be necessary, and syringing may be discontinued. During the same period, fewer root-waterings will be needed, but at no time should the soil be allowed to become quite dry. The most distinct and beautiful species and varieties are *M. Massangeana*, *M. Makoyana*, *M. Veitchi*, *M. rosea picta*, *M. illustris*, *M. Lindenii*, *M. Wallisii*, *M. medio-picta*, *M. zebrina*, and *M. Warszewiczii*. H. T. M., Stoneleigh.

NOTICES TO CORRESPONDENTS.

AZALEA SHOOTS DISFIGURED: *E. Hill*. Imported plants suffer sometimes if they have been taken from the open ground, owing to the tips of the roots being injured in the process, and the plants need a period of growth for complete recovery. We are unable to say what is the cause in your case, but it is something in the nature of a check.

CHRYSANTHEMUM FUNGUS: *W. H. P.* The Chrysanthemum cutting is affected with rust, *Uredo Hieracii*, in its young state. Remove all leaves that show fungus, in order to check its spread. Spraying with a fungicide, or with dilute Condy's Fluid, might assist. M. C. C.

CUCUMBER BINE: *C. W.* Some error in management, but we are unable to indicate anything nearer.

EMIGRATION: *S. E.* As good patriots, we ought to recommend the Cape of Good Hope, but really we should greatly prefer California, which, with the finest climate in the world, a plenteous rainfall, and

good soil, is a paradise for the fruit-farmer, Vine-grower, perfume-flower cultivator, rancher, &c. With your acquirements, horticultural and other, the road to success in either colony should not be difficult.

FUMIGATOR FOR A VINERY: *J. G.* The XL All may be recommended, not however using it unless the berries are larger than Marrowfat Peas, and using it of greater strength than the maker recommends.

GLADIOLUS BULBS DISEASED: *G. H. W.* The disease found upon your bulbs was figured and described in the *Gardeners' Chronicle*, September 30, 1876. As only a few of a large quantity of corms are so attacked, we should advise you to burn them; but if you wish to retain them, then, before they are planted, soak them in a solution of sulphide of potassium 1 oz. to the gallon.

GOOSEBERRIES DYING OFF: *M. S. & Sons.* In the absence of any visible cause, we must suppose must be due to some injurious application at the root.

INDIAN ORCHIDS: *E. M. Shakespear.* If you will send the plants, we will do our best to name them.

INSECTS: *J. H. W.* The name of the Chrysanthemum-leaf miner is *Phytomyza nigricornis*. The perfect insect, an attacked leaf, and a figure of the Ichneumon-fly, which is sometimes parasitic upon the *Phytomyza*, were given in the *Gardeners' Chronicle*, May 12, 1883, p. 593. Your specimens are very good ones, and have been neatly mounted.

NAME OF FRUIT: *P. Lee.* Sturmer Pippin.

NAMES OF PLANTS: Correspondents not answering in this issue are requested to be so good as to consult the following number.—*T. P., Dickson*, 1, *Asplenium biforme*; 2, *Didymochlæna truncatula* (lunulata); 3, *Polypodium inæquale*; 4, *Aspidium (Lastrea) serra*; 5, *Asplenium bulbiferum*; 6, *Litobrochia vespertilionis*.—*Enquire*, 1, *Erythronium Dens-canis*; 2, *Anemone Hepaticæ* double form; 3, *Anchusa officinalis*; 4, *Pteris serrulata*.—*T. W. C.*, 1, *Asplenium bulbiferum*; 2, *Cyrtanthium falcatum*; 3, *Acalypha musaica*; 4, *Acalypha marginata*; 5, *Dracæna intermedia*.—*Wm. W.*, *Rhododendron præcox*, *Odontoglossum triumphans*, and *Dendrobium primulinum*.—*W. J.*, *Medicago scutellata*, *Daphne odora*.—*E. M. Bergia nutans*.—*J. P., Chippenham*, 1, *Dendrobium Devonianum*; 2, *Cyrtanthus sanguineus*; 3, *Cyrtanthus Mackenii*.—*T. A.*, *Crocus Tommasinianus*, not *banaticus*.—*E. R.*, *Lonicera Standishii*.—*G. E.*, *Narcissus Pseudo-Narcissus* var. *major*.—*H. H.*, *Pittosporum undulatum*, *Epidendrum cochleatum* of gardens.

PEACH ROOTS: *A. Young.* Roots dead, and covered with fungus; but it is doubtful if the fungus is the cause or the consequence of their death.

PELARGONIUMS GOING BLIND: *C. B. W.* Over-fumigation, or too much or too strong manure, or other check to growth.

REMOVAL OF SHRUBS AND HERBACEOUS PERENNIALS: *W. E. J.* Unless you are a nurseryman, all trees and shrubs and Roses would be regarded as coming under the latter category, cannot be removed without first getting the sanction of the landlord. Herbaceous plants may be removed by the tenant, but he may not remove the soil with them.

TERM TO INDICATE A PLANT WHOSE FLOWERS APPEAR BEFORE ITS LEAVES: *R. G. G.* *Præcox* flor. præcoce.

TURF-CUTTING AND TURF-LAYING: *T. T.* It is a fair piece of work for one man and a boy to "race" off and raise 1000 one square foot turves in a day or ten hours, so that the price for the same if done by the day totals out, say, one man 3s. 6d., one boy 1s. 6d. = 5s. Turf-laying takes rather longer time, but much will depend on the nature of the turf, the land, and experience of the persons carrying out the job, and the nearness of the heaps of turf to the land to be laid down with it. Beating, rolling, &c., would still further add to the cost.

THE

Gardeners' Chronicle.

SATURDAY, MARCH 12, 1898.

SEEDLING APPLES.

IT is remarkable that in an age when hybridising and cross-breeding amongst plants have been so closely and successfully followed up by observant horticulturists, very little systematic work has been attempted with Apples or Pears. It has been said by such veterans as Mr. John Laing that they regretted that they had not given attention to the improvements of our standard fruits in the earlier days, so that they might have had a chance of seeing the result of their labours. But there are many plants which take far longer than Apples or Pears before the operator can prove whether his efforts have yielded substantial improvements. It is quite possible to obtain fruit within five years of the time of sowing, and in some cases a less time than this will elapse before fruit is produced, though it takes longer to prove a variety thoroughly, especially those which do not appear satisfactory at first, as they occasionally improve greatly as the plants gain strength. Seedling Apples will make a growth of from 1 foot to 2½ feet in a season, and if this be well matured by exposure to the sun it can be utilised as scions for grafting on Paradise stocks the following March. Under favourable circumstances, strong scions will produce a few fruits the second season from grafting, this being the fourth year from the seed, and I have even known them do so in the second year of the scion, but they are rarely strong enough to stand the strain, becoming stunted and barren for several seasons afterwards.

Very few Apples of proved merit are known to have resulted from crossing two varieties—in fact, it is doubtful if a dozen could be named of which the parentage has been known to the raiser and made public. Thomas Andrew Knight, the celebrated president of the Royal Horticultural Society, early in the present century, was most systematic in his work, and he has left the records of most of his seedlings. The best known of these are the following: Bringewood Pippin, from Golden Pippin crossed with Golden Harvey; Downton Pippin, from the Isle of Wight Pippin crossed with Golden Pippin; and the Red and Yellow Ingestre from Orange Pippin crossed with Golden Pippin. Downton Pippin was at one time a fairly popular Apple, and its name was frequently applied to other and less useful sorts in the shops, just as Ribston Pippin is now often employed to designate very different Apples. A west of London fruiterer in a large business at one time made a practice of giving the name Downton Pippin to every small Apple he was uncertain about. It is now rarely seen in gardens, orchards, or nurseries, though it is one of the few Apples that is useful for dessert and cider too. The Red and Yellow Ingestre are

most interesting varieties from the fact that they originated from two seeds taken from the same cell in the fruit which resulted from the cross-fertilisation recorded. The "Red" variety is not so generally known as the "Yellow," which is a valued occupant of numberless gardens, but the former is still included in the catalogues of a few nurserymen, especially in the west of England.

A well-known Apple of excellent quality, Sturmer Pippin, was raised by Mr. Dillistone, of Sturmer, near Haverill in Suffolk, and is recorded as the result of crossing Ribston Pippin with Nonpareil; and as a late dessert variety, it is highly valued by many growers at the present time. Old Middlemas I have never seen, and I am not sure if it is in cultivation now, but it has been described by Dr. Hogg as having originated in Sussex from a cross between Old Nonpareil and Scarlet Nonpareil, being notable as a good dessert Apple, flowering very late and bearing freely. Coming to later productions, we have Welford Park Nonsuch, one of Mr. Ross's productions which is said to have been obtained from Golden Harvey crossed with Lamb Abbey Pearmain, but the latter is only a probable parent from its proximity, as the cross was not made artificially. A still more recent example of a cross-bred Apple is afforded by Allington Pippin, which is thought to be from Cox's Orange Pippin and King of the Pippins, but I am not aware that there is any definite information on the point. It is possible that it may be one of the late Mr. Laxton's seedlings, if so, his sons should be able to give some information about the variety.

Amongst the more numerous varieties of which only the seed-parent is known, some of the best Apples that have also yielded seedlings of sterling merit are the following: Devonshire Quarrenden has given us Worcester Pearmain, Golden Noble has produced Waltham Abbey Seedling; from Newtown Pippin we have Lamb Abbey Pearmain and Ord's Apple, both being recorded as from seeds in imported fruits of the parent; Cornish Gilliflower has yielded John Gidley Pearmain, Golden Pippin is the seed-parent of Court of Wick; while Ribston Pippin is the reputed parent of Cox's Orange Pippin, one of the best Apples in cultivation at the present time, and generally free from the defects of Ribston.

As regards the bulk of Apples in cultivation, some valuable, and many comparatively worthless, all are practically chance seedlings, the seed-parents of which are not even recorded. Taking as an example the celebrated variety first named, i.e., Ribston Pippin, one of the oldest Apples known in England, it is recorded concerning it that "pips were brought from Rouen in 1688 and sown at Ribston House, Knaresborough," and from one of these it is supposed the Apple originated; but even this is not a certainty, though the place of origin is beyond dispute. Another equally noted variety, though with a shorter history, Blenheim Orange Pippin, which was raised at Woodstock in Oxfordshire, probably towards the close of the eighteenth century, is of unknown parentage, nor have we any definite record that any variety sufficiently like it to be of the same probable origin has ever been raised from an intentional cross. It is the opinion of some who have given attention to the matter in the district, that many seedlings were subsequently raised from the original tree, and that to these we owe the varied form of Blenheim seen in gardens or orchards. If this could

be substantiated it would be a highly interesting fact, as indicating the possibility of a well-fixed variety perpetuating its characters in seedlings; unfortunately, we have no evidence in the case of Blenheim Orange that this has since been accomplished, nor is it the case with the Ribston, for the only result known from this Apple i.e., Cox's Orange Pippin, is distinct from its parent in nearly all its characters except its high quality. I have raised scores of seedlings from both these Apples, and have never succeeded in procuring any approach to a reproduction of the parent qualities. Another very distinct Apple, the Devonshire Quarrenden, has been cultivated in this country for over 200 years, yet nothing whatever is known of its origin, nor am I aware that any seedlings have ever been raised partaking of its characters in a notable degree. It is true we now have the "Winter Quarrenden," but though this was first shown as Stubbs' Seedling, it is not stated that it was a seedling from Devonshire Quarrenden.

Although the flowers of Apples are, as regards the majority of varieties, particularly adapted for cross-fertilisation, owing to the numerous stamens not all being mature at the same time, and to the position of the respective organs, and while this is undoubtedly effected in nearly every case, yet so great is the disturbance due apparently to long cultivation that the variability of the seedlings is remarkable. It is surprising, too, how rapid is the retrogression, for it is not uncommon in one batch of seedlings raised from seed yielded by the fruit of one tree (say Blenheim Orange, for instance) to have several forms that are but slightly removed from the Crab type in size and quality of fruit. According to my observations, a great majority of seedlings from self-fertilised fruits are absolutely worthless, and it may be taken generally that at least ninety per cent. are inferior to the parent. Even with the most careful and systematic crossing, the percentage of seedlings showing valuable characters is small, but this is the only method which should be pursued now by those desirous of improving our fruits. It is true that as regards Apples, the varieties are so numerous that there does not appear to be much room for additions, yet in certain directions useful work could yet be done. For example, late-keeping dessert Apples of high quality, which combine vigour of habit with free-bearing properties and hardiness, will always be in demand because they are never too numerous. Dessert, or culinary Apples, that mature their fruits early in the season, require improvement in their keeping qualities, and a really good early Apple that could be kept without serious deterioration for two or three months would be an acquisition. Then, in the direction of strengthening the flowers of Apples, and increasing their power of resisting frost, there is a great field open for the investigator, and one that should well pay for exploring. It is well known that the flowers of various Apples differ materially in size and substance, time of expansion, hardiness, and in what may be termed staminate or pistillate vitality, fitting them for regular fertilisation, yet we have scarcely any systematic records to refer to, and few methodical attempts have been made to utilise these characters in cross-breeding.

The size of the flowers, i.e., the relative development of the petals, is an important consideration from a protective point of view, as I have found that in all their stages up to the period of full expansion, the large flowers more

frequently escape injury by frost and wind than the smaller ones, which seems to be chiefly due to the fact that the essential organs are more sheltered. It has been thought that the extra development of the flowers in certain varieties is sometimes attended by a diminished vitality in the stamens or pistils. More than thirty years ago it was recorded in the *Gard. Chron.*, that "many of the varieties of Strawberry in the United States consist of three forms, namely females which produce a heavy crop of fruit, of hermaphrodites, which seldom produce other than a very scanty crop of inferior and imperfect berries, and of males which produce none. The males bear large, the hermaphrodite mid-sized, and the females small flowers. The latter produce few runners, whilst the two other forms produce many; we may therefore infer that much more vital force is expended in the production of ovules and fruit than in the production of "pollen." This has been quoted and commented upon by Mr. Charles Darwin and Professor George Henslow, and is a very interesting observation, but amongst the Apples there appears to be an evident advantage in the possession of large flowers. For example, six large-flowered varieties of Apples, Stirling Castle, Duchess of Oldenburg, Lord Suffield, Devonshire Quarrenden, Warner's King, and Cox's Orange, all set their fruit freely and abundantly, especially the three first-named; and in the case of Stirling Castle I have repeatedly had crops of fruit from this when nearly all others have failed. It is true there are some small-flowered varieties which set freely and regularly, of which Yellow Ingestre may be taken as an instance, and Worcester Pearmain also has not large flowers; but as regards the varieties generally, I believe that those with large flowers have a point in their favour, and it is certainly a matter worthy of attention in cross-breeding.

As to the time of flowering, though we have a great range amongst the varieties in cultivation, extending over quite three weeks where a large collection is grown under similar conditions, so much depends upon the season and the uncertain variations in the weather, that the early flowerers, like Duchess of Oldenburg, sometimes escape as freely as those that flower late. Court Pendu Plat is commonly called "the wise Apple," because it is one of the last to expand its flowers, thus presumably escaping the frosts which, during May, are so liable to do mischief; yet in some parts of England I have known this Apple flower about the third week in May, when it was year after year cut by frosts that occurred at that time with troublesome regularity. Lord Suffield, too, is a fairly early flowerer, yet it seldom fails to set a good crop; while Bess Pool, which is almost as late as Court Pendu Plat, is a very uncertain bearer. In consequence, I consider it is of greater importance to pay attention to the size of the flowers in cross-fertilisation for the improvement of the Apple, but in conjunction with this, thickness or substance of petals, and vigour of stamens and pistils must be secured.

Pomona.

NEW OR NOTEWORTHY PLANTS.

ODONTOGLOSSUM EPIDENDROIDES,
H. B. Kth.

It may seem more than curious that this, the first discovered species of *Odontoglossum*, upon which the genus was founded by Kunth, should not have been found again, in spite of more than a hundred species of the same genus having been discovered

and introduced into cultivation since it was discovered by A. v. Humboldt and Aimé Bonpland in the warmer region near the ancient town of Yaen de Bracamores, in north-eastern Peru, in August, 1802. The description given by Kunth in the *Nov. Gen. et Spec. Plant.*, i. 351, is fairly correct, but poor and insufficient; and the plate, obviously prepared from dried specimens in the same work, does not convey a proper idea as to the real dimensions of the natural plant. These imperfections of description and illustration may have been the causes which led Lindley to confuse this species with an entirely different one, and thus stigmatize one of the finest members of the genus with a certificate of "worthless." Reichenbach has corrected Lindley's error, naming his *O. epidendroides*.

the peduncle is not "ultra pedalis," but over 4 high; 4, the petals are of a sigmoid form; 5, the lip, not white, but shining yellow, with a large dark carmine-red blotch in front. Yet a careful study of the very characteristic column, with its peculiar auricle, the unguis of the lip, and its attachment to the column, the arrangement of the crest of the lip, &c., indicate sufficiently that it belongs to the *Humboldtia Odontoglossum epidendroides*. All that can be said about it is, that the diagnosis must be modified, and that the variety I discovered in a different locality is far superior to the species originally described.

The pseudo-bulbs are 10 to 12 cm. long, 4 to 5 cm. broad, oblong, elliptic, or lanceolate, strongly compressed, thick edged, and plainly corrugate; the leaves 25 to 30 cm. long

FIG. 58.—*ASPARAGUS PLUMOSUS*. (SEE P. 147.)

droides *O. Lindleyanum*, and given an exhaustive description of the original so far as the few scraps of herbarial material in the Berlin Herbarium would permit. This was all that Reichenbach and all others knew of this Orchid until a few years before the former's death, when fresh material, collected by myself, was sent to him.

It is now over eighteen years ago that I made my first acquaintance with this plant in its natural habitat. For a long time I have looked upon my plant with great scepticism; it combines a number of discrepancies in its characters, which others might consider more than sufficient to establish a new species with. These digressions are:—1, the locality of my plant is over 300 miles distant from that of the Humboldtian; 2, the description of the bulb by Reichenbach does not correspond to my plant; 3,

3.5 4 cm. broad, linear-ensiform, blunt pointed, flat and subcoriaceous; scape slender, 0.8 to 1.3 metres high, bearing at the top a loose, many-branched, flexuose panicle or raceme; bracts very small triangular acute; flowers wide open, 9 to 10 cm. across the petals, of a most brilliant yellow colour, and spotted with three to five large, but differently sized dark carmine blotches, the unguis of the lip and column white; sepals cuneate, oblong-lanceolate cuspidate, 4 to 4.5 cm. wide, the dorsal one sub-cymbiform; petals broader, cuneate, oblong-lanceolate, sub-sigmoid, cuspidate, reflexed, the upper part of the margin irregularly denticulate; unguis of the lip narrow, linear, erect, with a keel-like border on either side, and for about 4 mm. of its length connected with the column; blade reflexed, 3 to 3.5 cm. long, 1.2 to 1.5 cm. wide, oblong sub-pandurate, abruptly cuspidate, the margins finely crenulate or denticulate. The disk consists of two prominent, at their points slightly ascending horns, with a short abortive one between them, and four to five short sharp teeth on either side; column 2 to 2.2 cm. long, canaliculate, the upper half strongly incurved, with a broad, roundish, sometimes bilobed finely serrulate auricle on either side of the stigma.

From a floral point of view, *O. epidendroides* is one of the finest, and deserves a foremost place in any collection of Orchids. The flowers appear in great number, up to fifty and more, on a simple branched spike; they are of an elegant shape, great

a place in the temperate-house, and treatment similar to that afforded *Odontoglossum vexillarium*.

Though this plant was re-detected now eighteen years ago, it has not been introduced into cultivation up to this time. The locality in which it grows can

the traveller is compelled to camp out. On my first visit no live plants were collected, the herbarium specimens were all that could be got; and for a second expedition I have not been able to collect the necessary courage. *F. C. Lehmann, Popayan, January, 1898.*

THE CULTIVATED SPECIES OF ASPARAGUS.

(Continued from p. 124.)

A. lucidus.—An old garden plant, often called *A. falcatus*, which it resembles. It requires tropical treatment, and is an elegant climber for clothing pillars, &c., for which purpose it is grown in the Begonia-house at Kew. Rootstock a cluster of fleshy oblong tubers $1\frac{1}{2}$ inch long. The stems are thin, flexuose, with small spines, 4 to 6 feet long, branched freely, the branches clothed with narrow flattened falcate leaves from 1 to 2 inches long, arranged in fascicles of from two to six. They usually turn yellow in winter and drop off. Flowers axillary, small, white, succeeded by berries $\frac{1}{4}$ inch in diameter, which are pink or white when ripe, and contain one seed. Dr. Henry says it climbs over trees and shrubs in the Corea, and is clothed with white berries. It is a native of China and Japan.

A. medeoloides.—Better known as *Myrsiphyllum asparagoides*, under which name it was figured in the *Botanical Magazine* in 1866 (t. 5584). It is said to have been in cultivation before 1779. A few years ago it came into prominence as a decorative plant, and market growers supplied it in large quantities under the name of *Smilax*. It is still largely grown for its long plant stems and bright green leaves, which are useful for twisting round the stems of flower-stands, &c. The rootstock is a cluster of fusiform fleshy tubers, 4 to 6 inches long, and $\frac{3}{4}$ inch in diameter. The stems are from 6 to 9 feet long, thin and pliant, spineless, the branches short, zig-zag, and clothed with ovate thin bright green leaves 1 inch long. Flowers small, axillary, green. Fruit globose, pea-like, three-seeded. There are several varieties, distinguished by the size and form of their leaves. Common in South Africa.

A. officinalis.—The common *Asparagus* deserves to be included among plants grown for decorative effect, a few clumps of it in a border, or even a bed of it standing free on a lawn, being decidedly ornamental. In the rock-garden at Kew there is a mass of it on the end of a wall-like arrangement of stones overlooking the bog-garden; and here the effect of the long, elegant stems in summer, and particularly in autumn, when they are clothed with bright red berries, is most pleasing. The plant is, of course, easily obtained, either from roots or seeds. It is wild in Britain, and also in various parts of Europe, N. Africa, and Siberia.

A. plumosus (fig. 58, p. 146).—This species was first described by Mr. Baker in the *Journal of the Linnean Society*, in 1875, from herbarium specimens collected by Cooper and others in South Africa. It is probable that Cooper introduced it into Mr. Wilson Sander's garden, for there was a large plant of it in the Succulent-house at Kew, in 1879, under the name of *A. consanguineus*. In the *Gardeners' Chronicle*, for 1878, it is noted as a new garden plant, which had been introduced from Natal by Messrs. J. Veitch & Sons. Mr. Bull offered it as a new plant in 1879 under the name of *A. consanguineus*. It is now one of the commonest of indoor plants, being of exceptionally elegant habit and easy to cultivate, whilst its fronds are useful in many ways. It has terete green spinous-climbing stems, which sometimes attain a height of 10 feet or more, the branches spreading horizontally, and branching again in such a manner as to form a flat frond-like arrangement, the leaves being very numerous, in clusters of about a dozen, bright green, and $\frac{1}{2}$ inch long. Flowers usually solitary, white, star-like, succeeded by globose black berries containing one seed. A native of South Africa, where it climbs over bushes, &c., in moist situations. There are several named varieties of this, most of which have originated in gardens. The most distinct is

FIG. 59.—*ASPARAGUS RACEMOSUS TETRAGONUS*.

Showing:—1, Young stem; 2, mature stem, with spines; 3, leaf-whorl; 4, leafy branch. (See p. 148.)

substance, and remarkable in colour, and as if varnished. It is a native of Peru and Ecuador, epiphytal on trees in dense, damp woods on the eastern declivities of the Andes, at an elevation of 800 to 1200 mètres above the sea-level, and in its natural habitat the flowers appear in the months of December and January. *O. epidendroides* will require

only be reached by travelling on foot for many days—and what travelling! The indescribable path leading to it, through luxuriant primeval forests, and across foaming ravines and rivers, is one of the worst of the many dangerous journeys I have undertaken in the Andes. There are besides no human beings living in the vicinity, and during the entire journey

A. plumosus nanus, which is badly named, the plant being at least as long in stem, and robust as the type. It is distinguished by the fulness and flatness of its fronds, and by its refusal to multiply by means of cuttings, division of the plant or seeds being the only methods that answer for it. I believe this plant is a seedling-sport from the old original *plumosus* grown at Kew. A figure of it was published in the *Gardeners' Chronicle* in 1881, and is here reproduced. It obtained a First-class Certificate in 1881. Other varieties, more or less distinct, are tenuissimus, with longer, less numerous leaves than the type, also called *albanense*; *declinatus*, raised in the nursery of Messrs. Backhouse & Sons, of York, and differing in the drooping arrangement of its branches; *cristatus*, with branches less flattened, and each branch terminated with a tassel-like cluster of branchlets and leaves; *comorensis* does not seem to be anything more than the type. With the exception of the variety *nanus*, all these forms are easily propagated from cuttings formed of the branchlets.

A. racemosus.—Messrs. Veitch & Sons introduced this species from Mauritius, and included it among their new plants of 1880. "The stems are very slender, and furnished with still more slender branchlets and spray, clothed with linear cladodes or false leaves of bright glossy green. It is a most desirable plant for the conservatory and warm-greenhouse as a pillar and trellis-climber." I do not know the type, which is spread throughout the tropics of Africa and Asia; but the Cape form of it is represented at Kew under the name of variety *tetragonus* (see fig. 59). This is a vigorous grower, with woody stems 9 feet long, prickly at the base, fawn-coloured, freely branched above, each branch having at its base a sharp spine $\frac{3}{4}$ inch long. The leaves are of a grey-green hue, four angled, $\frac{1}{2}$ inch long. Flowers in racemes 2 inches long, whitish, very fragrant. Berry, red, globose, pulpy, one-seeded. An excellent climber for rafters, pillars, &c., growing vigorously under ordinary treatment. Its root-system is a dense mass of tubers.

A. retrofractus.—Although sent out as a new plant, under the name of *A. retrofractus arboreus*, in 1890, this species was cultivated by Philip Miller in 1759, and I find it was in the Kew collection in 1872. It is now a fairly popular garden plant, on account of its vigorous habit, bright green colour, and elegant Larch-like leaves. It is equally useful for training up pillars, on the naked stems of Palms, &c., in greenhouses, or for suspended baskets. The stems are 6 feet or more long, woody, slender, grey, freely branched, zig-zag, with small prickles at the base of the branches, which are very slender and wiry, and clothed with crowded clusters of hair-like bright green leaves, an inch long. Flowers axillary, in umbels, small, white. Berry small, globose, one-seeded. A native of South Africa. *W. Watson.*

(To be continued.)

ORCHID NOTES AND GLEANINGS.

CATTLEYA TRIANÆI VARIETIES.

FOR some years *Cattleya Trianæi* was a first favourite; then came some large importations of a very bad type of it, and its hold on the amateur was considerably shaken. Recent importations of fine types seem to have thoroughly re-established it in favour, and for the last year or two its varieties have contributed some of our most beautiful winter flowers.

The variation in the type is so great, that in every garden where several are in flower one or two will strike the grower as being extraordinary, and an opinion will be asked. Many extremely beautiful varieties have been sent during the last fortnight, many of them so dissimilar that they afford a very good object-lesson on the difficulties which the earlier workers in the field must have experienced in determining which were species and which varieties.

F. W. Moore, Esq., of the Royal Botanic Gardens, Glasnevin, Dublin, sends *Cattleya Trianæi*, Glasnevin variety, a very showy flower, with sepals and petals

white, slightly tinged with lavender, which delicate hue also runs round the rich deep purple of the front of the lip. Mr. G. W. Marsh, gr. to T. P. W. Butt, Esq., Arle Court, Cheltenham, sends *C. Trianæi*, Arle Court variety, a grand flower of the *C. T. Eboracensis* class, with light rose-coloured sepals and petals, the latter bearing a distinct purple line at the tips. The lip is intense crimson-purple, the zone orange.

Of quite a different class, though equally beautiful, are three sent by Mr. Fred. J. Thorne, gr. to Major Joicey, of Sunnysdale Park. The handsomest of these has a gorgeously-coloured flower, still further embellished by a half-inch wide fringed lavender-coloured margin; another is a splendid flower, of an uniform soft Peach-blossom hue, like a *Cattleya Schroderæ*; the third is peculiar by its bright majenta-crimson plain-edged lip. H. Brittan Evans, Esq., of Clifton, sends two, the one a clear white, with a very slight tinge of pink; and the other a perfectly-shaped flower of the *C. T. delicata* class.

Several grand flowers are sent by Joseph Broome, Esq., of Llandudno, who calls attention to the fact that the two remarked on last year, the one as having the general colours of *C. Mendeli*, and the other the appearance of a brightly-coloured autumn *labiata*, are even finer than last year.

ORCHIDS AT MR. H. A. TRACY'S, TWICKENHAM.

Most of our amateurs who have commenced collecting Orchids during the last few years, have found the little establishment in the Amyand Park Road very useful in enabling them to obtain small sound plants of the chief showy species at moderate prices, and many whose collections have been formed, still frequent the place and seldom go away without buying. There are invariably numbers of good plants in flower, but, as the proprietor remarks, most of the plants are sold either in bud, or as soon as the flowers open, and hence there is seldom a very great show, nothing being retained for that special purpose. At the present time in the largest intermediate-house the varieties of *Cattleya Trianæi* contribute the most of the display, and of these there are some very handsome forms exhibiting great variety in colour. There are likewise varieties of *Lycaste Skinneri*, and one named "Marmorata" has a very rich rose-colour, the lip marbled with white; also *Dendrobium nobile* and other *Dendrobiums*, some fine plants of *Phalænopsis Schilleriana*, with stout branched spikes and other popular Orchids.

In the *Cypripedium*-house there are in flower *C. × Harrisianum superbum*, and *C. × H. nigrum*, still two of the finest dark-coloured hybrids; and a very handsome *C. × Swinburnei*, some *C. exul*, *C. Spicerianum*, *C. Lathamianum*, *C. villosum*, *C. Boxalli*, *C. × Leeannum* and others, and in bud several strong *C. Druryi*, a peculiar variety of *C. callosum* and other species.

In the other houses some of the varieties of *Cœlogyne cristata* are in bloom; a number of *Odontoglossum Rossii majus*, a good specimen of *Ada aurantiaca*, *Odontoglossum Roezlii*, and *O. R. album*, *Sophranitis grandiflora*, *Oncidium*, &c.

The forcing of Lilies and Daffodils for cut-flowers, is extensively carried out, and a fine display made by the Daffodils at the present time.

CYMBIDIUM TRACYANUM.

This handsome species, which first appeared as a single plant with Mr. H. A. Tracy in 1890, and was illustrated in the *Gardeners' Chronicle*, Jan. 31, 1891, p. 137, appears never to have been imported in bulk, and the addition to its number in gardens is due to the appearance of one now and then among importations. A fine flower of an arrival of that kind is sent by Mr. James Keeling, nurseryman, Mount View, Glossop Road, Sheffield. The markings of dark purplish chocolate on the greenish-yellow of the sepals and petals seems slightly darker than in the original. The cream-white labellum with the numerous hair-like processes, and red-brown spots, and the peculiar fragrance of the flower are as in the type.

A LITTLE CORNISH GARDEN.

(Continued from p. 93.)

FEBRUARY. — The recent hurricane seriously marred my little garden's February aspect, and I feel bound to acknowledge that the Cornish hedges have scored heavily by the side of my poor efforts. The furze or gorse has for a month past been blazing in golden glory, and has come out of the windy ordeal scatheless. In his latest book, Mark Twain writes of a part of Australia that "the gorse and the broom were a fine accent in the landscape. Here and there they burst out in sudden conflagrations of vivid yellow against a background of sober or somber colour, with a so startling effect as to make a body catch his breath with the happy surprise of it."

However, in spite of the elements, I have had a brilliant show of Crocuses, a variety of beautiful Snowdrops, and several other flowers, golden yellow, gaudy blue, and other colours too, of interest and beauty. My Primroses, also, are daily becoming more and more a mass of flowers, and I could on February 2 have picked many hundreds from a narrow border but a few yards long. Although the yellow Primrose appeals to me as the most beautiful of all, yet I have several enormous and very attractive blooms of other colours; but I can see little beauty in the pale washed-out purplish flowers which are produced in such large proportions by an average packet of Primrose-seed. Still, as an old verse (presumably Campion's) has it:—

"Give beauty all her right!
She's not to one form tied;
Each shape yields fair delight,
When her perfections bide.
Helen, I grant, might pleasing be,
And Rosmund was as sweet as she."

And, as Shirley said, "There's wit in every flower, if thou canst gather it."

I suppose most people will agree that *C. luteus*, with its varieties, is altogether our most precious species of *Crocus*. The beautiful golden-yellow flowers, when seen against a green background and exposed to full sunshine, afford one of the sights of the floral world. Each flower will be found, if examined, to have the tube around the style at least half full of honey secreted by the ovary. The great majority of *Crocus* species produce flowers which are purplish or lilac in colour; still there are interesting differences, and all are worth growing. The deep orange colour of the stigma of *Crocus vernus* is a gorgeous object, and shows to special advantage in the white varieties. The two earliest species to bloom with me were *C. reticulatus* and *C. Imperati*.

Crocuses are obviously suitable for naturalising in grass, for practically every species blooms in late autumn or early spring, before the grass begins to grow.

This remark also applies to Snowdrops, of which several beautiful species are now to be obtained from the florists. Of all the kinds, *G. Elwesii* most strikes my fancy, but I find the flowers rather variable, some being almost globular, and others oblong in shape. The green grooves on the inner segments of the perianth also are very variable in depth of colour, some being quite pale, and others emerald. These grooves produce and hold the honey, to obtain which an insect visitor must knock the processes which project from the anthers towards the petals, and thus bring down a shower of pollen on his body. The green markings on the inner petals (the outer segments of the perianth are pure white), largely contribute to the beauty of the flower. The orange-coloured stamens also afford added beauty. The scent is not really pleasant to most persons. *Galanthus Imperati* has given the larger flowers, but they strike me as coarser than those of *Elwes*' species. The latter in nature is said to be associated with *Chionodoxa*, one of the most beautiful hardy flowers recently made common in England. I have some splendid clumps of *Chionodoxa Lucilæ*, *C. Sardensis*, with flowers of darker blue, and *C. gigantea* with lilac tips to its petals. In appearance they somewhat resemble the *Scillas*, especially *S. bifolia*, of which I have a charming clump now in flower. A mass of blue and white Roman Hyacinths

has been much admired, although the flowers seem to me a little too waxy. For weeks past the six-rayed stars of *Triteleia uniflora* have afforded continuous display. Its beauty, hardiness, and season of flowering should cause the *Triteleia* to be much more grown.

Several species of *Anemone* are in flower, but of these I must write another time. I have also *Cyclamens*, *Daisies* (of which the double kinds are not to be compared to the beautiful wild one—descended, one may well believe, from the flowers plucked and dropped by naughty imps who for a quarter of an hour frolicked in the flowery meadows of heaven), *Arabis*, *Wallflowers*, *Polyanthuses*, *Muscari*, *Narcissi*, and other beautiful plants in bloom. But I think that the loveliest of all is the rich dark flower of *Iris reticulata*, with its glowing blotches of orange; and its markings of white, black, and every shade of violet. The plant is named from the netted character of the bulb. It is amusing to note the assumed etymological wisdom in many descriptions of the flower. "Blue flowers reticulated with gold," "of a rich violet-purple, veined and reticulated with a darker shade," so run the descriptions in two well-known publications. *Iris reticulata Krelagei* is also in flower, but is a much duller object than the type.

The past month has been a month of exceptional sickness, so that I have not been able to give much thought or attention to my garden. Fortunately, it has gone along all right without my care, thus contrasting with the glass-box gardens of the extravagant, which require continuous ministrations. Open-air gardening is the kind which I recommend to country doctors, who cannot, by the nature of their occupation, give that regular attention to plants within doors without which they are doomed to failure. I find gardening a most satisfactory hobby in many ways. For one thing, it can be plied within call of the surgery-bell; moreover, it is a great help in conducting friendly intercourse with patients. Most people of every class are interested in some branch of gardening, and are glad to hear tidings of Peas, Potatoes, or Pansies.

A doctor can do much to foster intelligent gardening practice, both by example and teaching; and he has many opportunities of spreading beautiful flowers by wise gifts of seeds, cuttings, or plants. The English cottage garden is sometimes a little gem of beauty; but it is much more often an untidy neglected piece of waste ground. Country parsons and doctors might do a great deal towards altering this. *Henry Roberts.*

THE LARGE-FLOWERED LILY-OF-THE-VALLEY.

CONVALLARIA majalis grandiflora or Fortin's large-flowered Lily-of-the-Valley, is a plant with a certain future. As a proof, I send you with this a box containing forced plants of this fine variety; also a photograph of a basket showing the plant in a forced condition in winter, and side by side with a pot of a good but old variety of forced Lily-of-the-Valley, such as is grown in and exported from Germany (fig. 60). In this photo, the vigour and habit of *Convallaria Fortini* are seen to be far superior in all ways to the variety of Lily forced hitherto, and that it is only a question of time before Fortin's variety supersedes the older kinds.

Fortin's variety when forced, grows from 11 to 12 inches high, and the racemes bear from fifteen to eighteen flowers each. The plant possesses this great advantage that it bears simultaneously with the flowers fine leaves, while with the older variety these are formed later. As will be seen by the specimens sent, the flower-stems are strong and firm, and remain so when the variety is forced, though they may be a foot high. This is an excellent quality in a market plant. This Fortin variety is easily distinguishable from the older sorts of forcing Lilies. The foliage is a different tint; it is a bluish, glaucous green. [The inflorescence is erect, giving off flowers on all sides (not drooping and secund as in the common form), and larger. *Ed.*]

The coloured plate given in the *Garden* on Sept. 4, 1897, is true as regards the size of the flowers

and their colour, but is misleading as regards the habit. The leaves and flower-stems are always stiff and erect, never drooping as in the illustration. It is painters' licence to wish to improve upon Nature that he may produce an "artistic" picture.

I do not know how Fortin's Lily-of-the-Valley would force for Christmas and the New Year, or rather, my experiments in that direction have so far failed; but for use in January and February, Fortin's variety is superior to the other. The flowers are as large as those of *Clethra arborea*. *Otto Froebel, Zurich.*

FIG. 60.—THE LARGE-FLOWERED LILY OF THE VALLEY
(Spike real size, plant reduced $\frac{1}{3}$.)

THE ROSARY.

HYBRID SWEET BRIARS.

It was a happy thought of Lord Penzance's when the cry was raised that we wanted some novelty in our Rose gardens, to devote himself to the crossing of the Sweet Briar; and, like all true gardeners, he has not hidden his method of procedure, or failed to tell of his failures, as well as of his successes, for in the pages of the *Rosarian's Year-Book* for 1892 and 1896, he has given a detailed account of his efforts of cross hybridisation, and shown us with what zeal and earnestness one who has reached his fourscore years can pursue a subject on which he has set his heart.

He did not work at random, but laid down distinctly the object which he was seeking, and the methods he used for that purpose; he tells us that he was very anxious to obtain a yellow Rose whose foliage and flower should have the sweet perfume of the Sweet Briar. The principle on which Lord Penzance acted is this, that the various races of Roses, however distinct they might seem to be, "and apparently opposed to one another in wood and spine, in habit of growth, in foliage, in hardihood, and other outward characteristics, are capable of uniting in the production of a common progeny, a progeny which is distinctly different from either parent, though generally bearing undoubted proofs of their origin in traces of both seed and pollen-parent." He was very anxious to obtain a good yellow Rose, and tells us how he crossed the Austrian Yellow, Persian Yellow, and Harrisoni, with such hybrid perpetuals as General Jacqueminot and Jean Chérpin. From this cross he obtained some hundreds of plants, but says that amongst those which had bloomed with him he could trace but very little effect of the yellow in the progeny, and thought the result indicated failure; but as these were not Sweet Briars, they are rather outside his original intention, and I think that it is to the Sweet Briars that Rose-growers mainly look to the success of this work. Some curious results were obtained in the course of the work: thus, he mentions that by taking away the hips as soon as formed, he was surprised to find that the plants gave a plentiful crop of second blooms, and that all through August and September, and part of October, he was able to gather a quantity of flowers, and adds that had he picked off the blooms immediately after flowering, he believes he should have had a more effective display; this, of course, increases their value. I have observed the same thing in some other single Roses without even gathering the hips; thus, in the Single White and Carmine Pillar sent out by Messrs. Paul & Son, of Cheshunt, I have had during the last two years a considerable quantity of autumnal blooms. He has also tried the effect of crossing some of these hybrid Sweet Briars with the pollen of Hybrid Perpetuals, but as yet success has not attended his efforts; and that also has an ominous signification, as coming from one who is in his eighty-third year. While Lord Penzance has attempted various crossings, his most successful results have been in a quarter which he did not himself expect, viz., that of the Tea Rose whereas, he says, nothing could be more distinct than the foliage of the two classes, and that in the hybrids obtained he has had strong evidence that the cross has been effected. As yet, no bloom of these cross-hybridisings has had more than two rows of petals, but he is sanguine that more double flower will be obtained; and as the entire stock has passed into the hands of Messrs. Keynes, Williams & Co. of Salisbury, it may be that as they have a large sale for them, they will be tempted to carry on still further these interesting experiments.

Certainly two of the most remarkable Roses out of the sixteen which have been distributed are Lord Penzance and Lady Penzance, the former the result of a cross between the Sweet Briar and Harrisoni, and Lady Penzance a cross between Sweet Briar and Austrian Copper. Some of the Roses differ considerably in habit, some being long and branching, and others pendulous; there is not, perhaps, so much variation in colour as one might wish, but we have shades of pink, rose, dark crimson, and scarlet-crimson, besides the soft yellow and fawn in Lord and Lady Penzance.

And now let us see how these are to be best grown: there are three ways in which their beauty may be utilized, those which have a pendulous habit form very pretty objects when grown as standards, the branches droop, and whether in flower or fruit, are exceedingly useful—although, as I have said, greater value may be obtained out of them by taking off the fruit as soon as the hip is formed. The most general way, however, in which I think they are most likely to be used is that of fence or pillar Roses: they form long straggling shoots which are quite suitable for a fence, and I have in my small garden a few of them thus used, and they are very pretty and

effective; also, they can be used as bush Roses. There is one point which must be particularly noticed in their cultivation: they ought never to be pruned, at least in the ordinary acceptation of that term; the shoots should never be shortened, for if treated like other hybrid perpetual and other Roses, they will never flower. Straggling and unsightly pieces may be cut out, so giving freer access to light and air. It is very difficult to make some gardeners understand that one system of pruning is not good all round; of course, these hybrids are perfectly hardy, and will stand any amount of cold. While I am on this subject I may mention a Sweet Briar which I was the means of introducing to the Rose-world, though I utterly disclaim all merit for so doing. A good many years ago, I noticed in the garden of my friend, Mr. Whitwell, who was then living near Darlington, a remarkable looking Sweet Briar; he did not know its origin, but found it in the garden when he took the house. It must have been tolerably old, for the stem was as thick as a man's arm; the foliage was decidedly that of the Sweet Briar, and the flowers, which had two rows of petals were beautifully striped. I brought it up to one of the meetings of the Royal Horticultural Society, and it was awarded a First-class Certificate—an honour which I hardly expected it to obtain, and I gave it the name of Janet's Pride, and placed it in the hands of Messrs. Paul & Sons, of Cheshunt, who, after some difficulty, obtained the stock of it, and distributed it to the Rose world, and one hardly ever sees a stand of garden Roses at any of our exhibitions in the earlier part of the season that does not contain a group of it.

The Rose world is much indebted to Lord Penzance for the additional pleasure he has given to all lovers of the flower by the successful results of his skill and intelligence, and also for his generosity towards the National Rose Society. For some years he has given a £5 5s. Cup for a stand of garden Roses, which has been competed for at the metropolitan show at the Crystal Palace, and thus tended to encourage that branch of Rose growing in which he has been so successful. *Wild Rose.*

FORESTRY.

WORKING PLANS FOR FORESTS.

It is a painful fact that in many branches of business we are being rapidly cut out by foreigners and especially the Germans, so that to-day the expression "made in Germany," has become quite a bye-word among us. Unfortunately, instead of this stirring us to fresh exertions, we seem to regard it as Kismet, and bewail the "good old days" when things were far different. Many writers have clearly shown by statistics and other cut-and-dried facts that the success of the foreigner is largely due to their system of technical schools, and consequently to their thorough knowledge of their own particular business. In no case is this fact so patent as in the case of forestry. In Germany and France the forest officers, rangers, and guards, have a thorough knowledge of the duties required of them, and are carefully trained in special forest schools. Not only this, but large sample plots are formed to test such theories as the most profitable degrees of thinning, the best species of tree to be grown, &c. Above all, they study the requirements of the purchaser. What the wood-merchant wants is good sound timber and a supply that he can depend upon. If the English merchant wants a certain amount of timber for six months hence he knows he cannot depend on obtaining what he wants in England, owing to the fluctuating supply, and so he is willing to go to the extra expense of sending to Germany for it. This steady annual supply in Germany is owing to the systematic working plan which is drawn up for each forest, and in which it is arranged that an equal amount of wood should be cut over each year, at the same time insuring a steady annual income. Amongst other things, when a working plan is prepared, calculations are made to find out the most profitable rotation, taking into account the

money originally spent in formation with compound interest. For these and other reasons, the importance of a working plan cannot be too greatly estimated. As this requires a trained forest officer, doubtless many think this would entail too great expense, and that the result would not justify the means. Though I doubt this, I would suggest to such economists, that they should employ the services of forest officers at home on furlough from India. These officers have been through a three years' course of forestry at the College of Cooper's Hill, including tours to the forests of France and important places in England. Included in this course is six months practical work in the Black Forest of Germany. In India, where their duties lie, these officers have to form forests, out of waste land, or establish order in existing forests, and form working plans for them. This is identically what is wanted in England, and I think the employment of one of these officers at home on furlough for a short time would be of inestimable service to a large forest owner. If steps were taken in this direction, with our relative freedom from insects, with our mild winters and other advantages in our favour, there is no reason why we should not be able to compete with our foreign rivals on at least equal terms. *H. C. Walker.*

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Fig-trees.—In the colder parts of the country, Fig-trees are usually protected during the winter with bracken, straw, or similar material, and the practice is a good one provided sufficient care is exercised in uncovering the trees again at the proper time. There is a great risk, if the covering is retained in full, that growth may take place to some extent before the covering is removed, and the trees thereby receive a severe check, jeopardising the current season's crop of fruit. The time to uncover varies with the seasons and the district; and in southern counties it will be safe to do so in the middle of this month, while in colder parts it will be soon enough ten days later. If growth should have commenced, only the major part of the covering should be taken away, the tender shoots and fruits will then be protected by what is left, and they will get gradually hardened by access of light. Small fruits of last season's growth should be rubbed off the shoots, for although these will occasionally increase somewhat in size and ripen, they are never satisfactory, and only divert the energies of the tree from perfecting this season's crop. In pruning the trees, let the whole of the weaker shoots be removed entirely, and thus afford the stronger bearing wood plenty of sunlight, for the leaves of the Fig grow so large that it is easy to overcrowd. All young shoots that are left should be nailed-in with 9-inch spaces between them, and as the branches increase in size very fast, some few of the older ones should be removed entirely annually, and thus renew the vigour and youthfulness of the trees, gradually and constantly. Those shoots that are nailed-in should not be tipped or shortened in the least, the fruits being always borne at the points of the previous year's shoots, hence, to shorten them is to rob the trees of their fruit-crops. The Fig always bears the best when it is allowed to grow into a head above the top of the wall. Such trees do not come up to the usual standard of correct pruning and training; but the wood made under these circumstances is short-jointed and fruitful, and the fruit better in colour and in quality; and even such a shy bearer as the Brunswick fruits freely if allowed to grow rather wildly in this manner; but it is a method that can only be followed in the southern counties, in colder ones the fruit would not get warmth sufficiently to ripen it. Standard Figs succeed in sheltered positions on the south coast of England, notably at Tarring near Worthing; but in very severe winters the trees suffer from frost unless the practice is followed of storing them in cellars, &c. After the Fig-trees are pruned and nailed, let the borders be loosened with a digging-fork, but afford no manure, Fig-trees being, as a rule, when on outside-walls, too vigorous in growth, and too little inclined to fruit well, without manure being specially placed within reach of the roots, these rambling far and wide in the richly-manured borders adjacent. As a counter

agent to rich feeding grounds for the roots, it is advisable to employ old mortar, charred soil, and even to curtail the extent of the roots either by annual pruning of them, or building a wall round the spot. The finest out-of-doors Figs are Brown Turkey and White Marseilles; both of which are sure and good croppers, and have fruits of a useful size. The Brunswick has the largest fruit. It should only be planted in very warm situations.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorset.

Chysis.—The following varieties of these deciduous Orchids, *C. bractescens*, *C. laevis*, *C. aurea*, *C. Limminghei*, and the distinct hybrids *C. Sedeni* and *C. Chelsoni*, are now making new growths, and if these be strong enough to flower, water the plants but sparingly until the flower-spikes are seen to be growing faster than the growths, when water may be more freely given. Small growing plants will require generous treatment in every respect. These epiphytal plants succeed well suspended close up to the roof-glass in a shady corner of the Cattleya-house. Examine the plants every day for small yellow thrips, for if these become numerous, success is hopeless. Do not disturb the plants by repotting them now, but defer the work until the flowers have faded. These plants require perfect drainage, and a rooting medium composed of two-thirds sphagnum-moss and one of fibrous peat, with a few lumps of charcoal added, or thick pieces of crocks. Keep the plants at the warm end of the Cattleya-house throughout the growing season, and thoroughly water them each time the compost becomes dry, but carefully avoid constant saturation of the soil. Propagation may be effected in the following manner:—If the plant is in vigorous health, and there is no necessity for root disturbance, make an incision with a sharp knife half-way through the rhizome between the old pseudo-bulbs, and when the plant has done flowering the rhizome may be cut through. The oldest bulbs will soon make new breaks, but do not repot the severed pieces until the following year, when the old roots have sent out laterals.

Vandas.—Such plants as *Vanda teres*, *V. Hookeriana*, and the distinct hybrid *Miss Joaquim* should be placed well up to the roof-glass, either in the Mexican-house or in a sunny position in the plant-stove, and every encouragement given them until the flowers open. No difficulty is experienced at Burford in getting these beautiful Orchids to bloom freely; the plants are fixed to Teak-wood rafts, and each stem is allowed to grow to the height of 6 or 7 feet before cutting them down. By this method the growths become strong, and rarely fail to produce flower-spikes. From this date the plants will be syringed overhead with soft tepid water twice or thrice daily until the flowers begin to open. The distinct *Vanda Kimballiana* and *V. Amesiana* are also starting to grow, and those plants that require additional rooting-space should be attended to at once. Baskets or upright Teak cylinders are preferable to pots, as these allow a freer circulation of air amongst the roots. In the case of plants that do not need this extra space, remove the surface potting material, and substitute fresh moss. The plants should be placed close to the roof-glass in the Cattleya-house, and in the lightest and best-ventilated part available. As these species throw their roots out into the air in all directions, it is advisable to syringe in amongst them occasionally, and to keep their immediate surroundings moist during growth.

Miscellaneous.—If such plants as *Peristeria elata*, *P. pendula*, *P. Lindenii*, and *P. aspersa* have been at rest in the intermediate-house, remove them to the shady side of the East Indian-house, and afford an abundance of water until the pseudo-bulbs have attained their full size. A rare Orchid now in bloom at Burford is *Laeliopsis domingensis*, a plant that requires plenty of direct sunlight, and an abundance of water while growth is being made. The south side of the East Indian or Mexican-house is the best position for it, and baskets with a very thin layer of peat and moss are more suitable than pots. When the new bulbs have been made up, the plants may be dried almost as much as *Odontoglossum citreum*. In the cool-house, plants of the pretty *Pleione humilis* that have just passed out of flower should be given fresh potting material. Shallow pans, plenty of drainage, and a compost of equal parts fibry loam, peat, and sphagnum-moss, well mixed with a moderate quantity of soft silver-sand, is the best culture. Suspend the plant near to a ventilator, or some other position where it will obtain plenty of fresh air, and afford plenty of water all through its

period of growth. The curious-flowering *Nanodes edusæ* must now be given frequent and liberal supplies of water. It should be grown in the Odontolossium-house, either in baskets or shallow pans, as the beauty of its flowers can be seen only by looking through them towards a strong light.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Heliotropes.—If the requirements of those plants which flowered last year have been carefully attended to, they should be capable, on being placed in an intermediate temperature, of making an immediate start into growth. If a further stock of plants be required, some of them may be placed in a brisk heat to furnish shoots suitable for making cuttings. Cuttings are fit when 3 inches long, and then should be inserted in a light sandy soil, coated with silver-leaf, afforded water, and then be placed in the propagating-frame or house, and be rooted quickly, and in turn these will yield a further batch of cuttings. Growing plants in need of repotting should have attention forthwith, using a mixture of good loam half a year in stock, leaf-mould, some sand to make it porous, and a small portion of spent Mushroom-manure, which has been rubbed through a fine-meshed sieve. Let the plants which have been shifted be syringed daily, but afford them no water for a few days. Standard plants form nice decorative objects, and they may be readily grown of a good size by training up a single growth to form a stem, and pinching out its point when the desired height is reached, and rubbing off the lateral growths, with the exception of five or six near the point, which may grow to 3 inches in length, and be then pinched out in turn, these will soon push forth several other growths, and thus in a short time form a crown.

Fittonias are pretty foliage plants of dwarf habit, of much value for decorative work of various kinds. Cuttings root readily at almost any season, being inserted in the pots in which they are to be grown, viz., 3 and 4-inch pots. *Fittonias* are inmates properly of the stove, and they are very effective when associated with small Ferns, *Selaginellas*, *Lycopodiums*, and green-leaved plants of dwarf habit.

Libonias.—Cuttings may still be struck of the varieties of *Libonia*, but no time should be lost in so doing. Strike them in a light sandy soil, placing them round the side of a 4 or 5-inch pot, and employing a brisk bottom-heat and considerable amount of moisture in the air. If large specimen plants are required in a short space of time, three plants may be grown in a 7-inch pot, but for ordinary purposes a single plant grown in a 5-inch pot will usually suffice. The plants grow well in loam two-thirds, leaf-mould one-third, and sand, but for the last shift rotted manure should be employed as well.

Tuberous-rooted Begonias.—The bulk of tubers may now be placed in sand, and in an intermediate temperature, in order to start them into growth. Tubers that were introduced at an earlier date will stand in need of potting, otherwise the roots may get damaged if allowed to extend much in the leaf-mould. These *Begonias* require a rich compost in order to insure robust plants, and a suitable mixture consists of good fibrous-loam one half, and the rest cow-manure dried and worked through a fine-meshed sieve, leaf-mould, sand, and a small quantity of charcoal-dust. If possible, stand the plants on some solid material, shingle, coal-ashes, &c. in a shady position, and afford a temperature 55° to 60° at night. Much water will not be needed for some time after potting them, but care must be taken that they do not suffer lack of it, or the young roots will fail to start away into the fresh compost.

Sericographis Ghiesbreghtiana.—As the plants go out of flower, take off all the shoots suitable for forming cuttings, and insert in sandy soil; cutting back the plants, and placing them in heat to produce a further supply. It is not necessary to keep the old plants after a sufficient number of cuttings are struck, young plants growing and flowering much more freely than old ones.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

Brussels Sprouts.—As this is a vegetable which requires a long season to perfect its growth, and good Sprouts are often in demand as early as November, seed should forthwith be sown in boxes or seed-pans thinly, and placed in warmth of 50° to 60°; a bed equal to the needs of the establishment should be sown on a warm border. Pricking off

should be done in all cases when the seedlings have made four or five true leaves in rows of 9 × 3 inches, the bed being made friable and rich, the aim being to secure sturdy, well-rooted, plants. Excellent varieties are Rosebery, Exhibition, The Wroxton, and Veitch's Paragon. Autumn-sown Sprouts may be planted in their permanent quarters, before growth to any extent has taken place or they crowd each other. Afford the plants a space of 2½ feet apart each way.

Planting Broad Beans.—If seeds of these Beans were sown in frames and boxes as recommended in my calendar in January, and the plants have been hardened off, transplantation in single rows, 2 feet apart, and 6 inches from plant to plant in the rows, may now be performed. In doing this lift the plants carefully, so as not to cause injury to roots or stems, and having planted them in little trenches with a perpendicular back, afford, before filling in fully, a good watering to settle the soil about the roots, then finish the filling in, make firm, and protect them with evergreen twigs of some sort. In the open quarters make another sowing of Longpods.

Parsley.—If seed of Parsley were not sown last month in drills in the open garden, it should forthwith be sown. The land should be in good heart, and situated in an open spot, and the drills not nearer together than 1½ feet.

Sowing Seeds and Planting Pot Herbs.—Seeds of Chervil, Burnet, Fennel, Borage, Sweet Marjoram, Marigold, Savory, may now be sown on a warm border where they are to remain, covering them in the case of the more tender species with a hand-glass. The seedlings should be thinned out to 3 or 4 inches apart. Sweet Basil being the most tender of herbs, sowings should be made in a warm frame, or in pots placed in heat, the plants being set out in May. Herbs should be planted altogether on a warm open border in order to save time in gathering for use. The following may be planted this month, and as late as the middle of April:—Balm, Burnet, Tansy, Feverfew, Savory, Pennyroyal, Camomile, Thyme, Hyssop, and Tarragon.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Late Peaches.—The buds on the trees in the late houses having begun to swell, forcing may forthwith commence if fruit be required late in the season. Still, it is possible to retard the trees a little longer by affording every opening for air to enter the house, only closing the ventilators when sharp frosts are likely to occur, letting the hot water circulate somewhat to avoid an accident. In unheated houses the trees are now coming into bloom, and there seems to be a likelihood of a good set of fruit with us. Before the flowers begin to open, fumigate or vaporise the trees, fumigating rather strongly if tobacco-paper be used on two or three occasions. If the trees are in flower in any house, maintain the required temperature by means of the apparatus, affording an increase of warmth of 5° to 8° in the daytime, and endeavour to maintain a buoyant atmosphere by admitting air as freely as the weather will safely permit; and in all respects follow out directions given in an earlier calendar for Peach-trees in bloom.

Early-houses.—Let the disbudding be gradually carried out at short intervals of time, the tying-in of the young shoots, and the thinning of the fruit, once a day for the present receive proper attention, the trees being syringed, doing this operation thoroughly, and from both sides of the trees, so as to keep the trees free from red-spider. If brown-scale should appear on the rind, syringe the affected trees twice a week with soft-soap and water, at the rate of 2 oz. of the soap to 1 gallon of warm water. Aphid is sure to infest the trees at the first, and fumigation will require to be frequent, in order to get rid of it, XL All vapour being one of the safest means for killing aphid without causing injury to the tenderest leaves. Thrips will be destroyed by the same dose of vapour. Mildew, if it appear, should be checked in its earliest stage, with flowers-of-sulphur mixed into a thin paste, and then half a pint added to 2 gallons of water, and distributed by means of a syringe with a nozzle, and allowed to remain on the leaves, &c., for a few days, being then cleared off with soft-water. Mildew is not easily detected on the fruit in the early stage, which is that of minute white spots that are only a shade lighter than the skin.

Cherries and Plums.—While the trees are in bloom, the temperature of the house and their other require-

ments are similar to those of the Peach and Nectarine—indeed, Peach treatment may be followed through the early swelling and stoning period of the fruit; but in dealing with the breastwood it should be left 2 to 3 inches long. The Cherry-tree is subject to black, and the Plum to green aphides, and the latter to be infested with caterpillars. The caterpillars will be found rolled up in the leaves, and should be smashed with the finger and thumb.

Grape Gros Colmar.—Assuming that these Vines were started late in last month in order to have the fruit in perfection in early October, the buds will have considerably developed, rendering it imperative to secure the rods to the trellis, provided the break has been regular from base to summit. Attend to previous instructions in early vineries, and make sure that the borders are in a sufficiently moist condition to promote regular and continued growth. If a hot-bed exists in the house it should now be cleared out.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

The Rose Garden.—The time has arrived when the hybrid perpetual Roses, without an exception, should be pruned, although the wintry weather prevailing at this moment scarcely favours a commencement of operations; nevertheless, pruning will have to be performed, for most of the bushes of H.P.'s are already in growth. The pruning of Roses is an operation which should be entrusted to a person conversant with the habit and growth of the various varieties; hence, a Rose of naturally weak growth or constitution must not be pruned as severely as one of strong growth and robust constitution. Neither should all the shoots be cut to one height from the ground-level. Plants that are thus mishandled flower, of course, in due season, but the flowers are different as regards form and colour to those of the same variety where the proper amount of care is used. Briefly stated, the plants which are required to furnish very fine show flowers should be the more severely pruned, as a great quantity of growth is not so much required as good quality; therefore, remove all the smaller shoots and branches, and leave only the strongest. If plants are required to make a display in the rosary, the pruning should be less severe, but weakly growths should be removed entirely, as well as all decayed old wood, and the remaining shoots cut back to various heights from 6 inches to 1 foot, bearing in mind the while the constitution of the variety. Plants that are to be pegged down to the soil should have the leading shoots shortened back, and all the side shoots originating from these cut in close. Climbing Roses should have the tip taken from the strong growths, and all thin and flowerless and bare shoots removed. When pruning Roses, use a sharp knife, and make clean short cuts. The *sécateur* is a handy implement for use instead of a knife, or it may be reserved for snags only. As the wounds of the Rose seldom heal over it, it scarcely matters what instrument is used. The more tender Tea and hybrid Tea Roses should be left unpruned till the end of the month, and in cold exposed districts or gardens to the first week in April. China or monthly Roses, as they are called, should be thinned out, and as the flowering shoots spring from the collar of the plant, the weak ones should be cut down to that part. The other shoots may be left shorter or longer according to strength. Pillar Roses should have the oldest stems removed at the ground-level, laying in a corresponding number of strong new shoots at varying lengths.

Digitalis purpurea (Foxglove).—The spotted varieties of this plant should be found in every herbaceous border and shrubbery. It is also a fine plant for the centres of large beds. Those plants which were raised from seed sown last spring may forthwith be planted where they are intended to flower.

Campanula pyramidalis and *Campanula calycanthemum*.—The plants raised from seed sown last year will now be ready for planting where they are intended to flower. Let the sites be well manured and deeply dug, allow space for full development, and plant firmly.

General Remarks.—The planting of all kinds of shrubs, excepting Hollies, should be finished forthwith, deciduous species being already in growth. Climbers should be planted without further delay; roll gravel walks that have been rendered loose on the surface, choosing a dry morning when the gravel does not cling to the roller for the performance of this sort of work. The lawn and turf generally should be swept and rolled.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.
 Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

MEETINGS.

MONDAY,	MARCH 14	Annual Meet. United Hort. Ben. and Prov. Inst. at Caledonian Hotel, at 8 P.M.
TUESDAY,	MARCH 15	Cornwall Daffodil and Spring Flower Show at Truro (two days).
THURSDAY,	MARCH 17	Linnean Society Meet.

SALES.

MONDAY,	MARCH 14	Hardy Perennials, Carnations, Begonias, Dahlias, &c., at Protheroe & Morris' Rooms.
TUESDAY,	MARCH 15	Roses, Gladioli, Carnations, Hardy Bulbs, and Plants, &c., at Protheroe & Morris' Rooms.
WEDNESDAY,	MARCH 16	Japanese Lilies, Palm Seeds, Continental Plants, Herbaceous Plants, &c., at Protheroe & Morris' Rooms. Palms and Plants, from Ghent, also Roses, Fruit Trees, and Border Plants, at Stevens' Rooms.
THURSDAY,	MARCH 17	Clearance Sale of Glass Erections &c., at "Olanthigh," Pudding Lane, Chigwell, by Protheroe & Morris. Plants, Shrubs, Bulbs, Roses, &c., at Stevens' Rooms.
FRIDAY,	MARCH 18	Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—42°6'.

ACTUAL TEMPERATURES:—

LONDON.—March 9 (6 P.M.): Max., 45°; Min., 38°.
 PROVINCES.—March 9 (6 P.M.): Max., 48°; Valentia; Min., 39°; S.E. Coast.
 Cold, easterly winds; slight frost.

The Origin of Species by M. J. COSTANTIN published in the *Revue Scientifique* (November 27, 1897) an extract of a work of his, entitled *Les Végétaux et les Milieux Cosmiques*. He had already written several articles in the *Annales des Sciences Naturelles*, &c., illustrating the great effects produced upon plants by their surroundings; and he now bases his argument upon the particular case of Arctic and Alpine plants. The modifications upon plant-structures are not only "profound," but are made in "a relatively short space of time." Thus, annuals which are transplanted from a temperate to an Arctic climate, become perennials and dwarfs, such results being due to the too short a period for growth in dimension and maturation of seed.

If the plant be woody, the heat of the soil induces procumbency of the branches. Similarly, if annuals be transported to the tropics, transformations equally great, but exactly opposite in character in some respects follow; thus, as there is no low winter temperature to check and kill the annual growths, herbaceous plants and deciduous trees become evergreens. In tropical forests many plants growing in the shade are partially blanched, and thereby induced to become climbers; other species of the same genus not so situated, are not climbers, as species of *Convolvulus* in deserts, &c.

On the other hand, marine Algæ are modified in an opposite way. The water of an icy sea dissolves more nourishment than does heated water. The Polar Algæ thereby grow to enormous lengths and gigantic size. Besides such alterations as the above-mentioned, experiments show that if the conditions be constant, a fixation of characters is the result; and so varieties give rise to races; and just as these

occur abundantly under cultivation, so do they in Nature. Very often the origin of these "little species," or stable forms of varieties, is unknown; but it is not always so, and we then get a glimpse of the manner of birth of sub-species.

Some Darwinists, M. COSTANTIN notes, would assert that such variations are transient, and that variability is limited; but experiments show that we can induce varieties to arise "absolutely comparable in all their characters to alpine and Arctic plants, and by a prolongation of the experiment, these varieties can become races, and such are among the most constant of a Polar flora.

"We are thus led to conclude that one can only explain the general characters of arctic and alpine plants by adaptation. Hence, since all the arctic plants are perennials, it is because they live near the pole. It is the conditions of life which have created their hereditary characters."

The author observes, e.g., that the only perennial species of *Isatis* is *I. alpina*; so also the alpine species of *Draba* are perennials having their leaves in rosettes, while those of the annual species of the lowlands are not so. These coincidences can be multiplied indefinitely, and apply generally to the Linnean species. Moreover, the changes are not solely in the vegetative organs, for the flowers are more or less modified as well; and these "little" species have as much fixity as the "great" Linnean species. M. JORDAN proved the constancy of small differences in some 200 cases of "stable little species," and these have been confirmed by several other botanists. MM. THURET and BORNET submitted them to a vigorous control, and they thus wrote:—"Seven years in succession we sowed fourteen species of *Erophila* (*Draba*), and they have shown no variations nor hybrids." We have proved that these "espèces Jordanniennes" have been derived from Linnean types; we know, not only in what conditions they have arisen, but we are led to think by similar reasoning that the larger species may have arisen in the same way.

M. NAUDIN, in 1874, considered that the belief in the effect of the environment was exaggerated, and that plants varied "in virtue of an intrinsic and innate property of protoplasm," but as M. COSTANTIN points out, that cannot be proved, whereas in speaking of the action of the environment we simply describe observed facts and the results of experiments. All, therefore, the author maintains is that the plant re-acts to climatic "physico-chemical" conditions, varies in response to them, and the variations in due time become fixed.

He next considers the objections based on the ideas of hybrids and mongrels. To those who maintain that although crosses and mongrels are perfectly fertile, yet the supposed sterility of hybrids proves the parents to be true species, the author shows the utter inadequacy of this conception, for all florists know that perfect fertility is common enough in our numerous garden hybrids. He refers to the "indefinite fecundity" of *Ægilops speltaeformis*, the result of crossing Wheat with *Æ. triticoides*—itself a hybrid between *Æ. ovata* and Wheat. This cross was raised in 1856, and was still cultivated in 1870. It is true in some places there were reversion towards the original parents, but in 1880 M. COSSON re-examined it and asserts that it is a fertile hybrid, fixed, and has become a true species, since its characters no longer vary, and it has lost nothing in fertility.

After a further discussion of hybrids and varieties, showing that they often behave alike, M. COSTANTIN points out how a definition of species has had to be altered from time to time as criticisms have undermined the original notion of their absolute fixity; and that all inferences based on the sterility of hybrids have broken down. He will, therefore, hold to the definition of LAMARCK:—"The species is a collection of similar individuals, which perpetuate themselves in the same state as long as the circumstances of their situation do not change sufficiently to bring about variations in their habits, their characters and their forms."

In conclusion, M. COSTANTIN adds: "A species, as LINNÆUS used the word, is not stable. The criterion supplied by crossing allows no distinction between hybrids and mongrels."

ABBEY GROUNDS, TRESKO, SCILLY.—The pictorial view represented at fig. 61 is from the Abbey Gardens, Tresco, Scilly Islands. The cut tells its own tale; it is only necessary to add that the *Dracena* in luxuriant flower is the New Zealand *Cordylina australis*, a tree hardy in some of the southwestern counties, but requiring a greenhouse in most places. Our illustration is taken from a photograph by Mr. R. Preston, of Penzance.

NATIONAL ROSE SOCIETY.—The schedules for the Bath Exhibition, on June 23, and for that at the Crystal Palace, on July 2, are now issued.

"BOTANICAL MAGAZINE."—The plants figured in the March number are the following:—

Camptosema pinnatum.—A glabrous shrub, 3 to 5 feet high, with unequally pinnate leaves, the leaflets drooping, shortly-stalked, oblong, acuminate, each 6 or 7 inches long, 2 to 3 inches broad. The flowers are in short racemes, each about 2 inches long, with a cylindric calyx, slightly lobed at the edge, half the length of the cylindric lilac, papilionaceous corolla. A native of Brazil, flowered in the Palm-house at Kew; t. 7582.

Erythronium Hartwegii.—See *Gard. Chron.*, 1896, ii., p. 361.—A species with mottled leaves and flower-segments recurved, white, with a yellow blotch at the base; t. 7583.

Dracena Godseffiana, *Gard. Chron.*, 1894, ii., 212; t. 7584.

Hacquetia Epipactis, D.C.—As *Dondia Epipactis* this curious little Umbellifer has been known for upwards of 300 years; how long it has been in cultivation seems to be doubtful. It is not in *Aiton*, according to the editor, nor is it in *Miller's Gardeners' Dictionary*, ed. 8; t. 7585.

Epidendrum xanthinum.—A tall-growing Brazilian species, with alternate sessile, oblong-acute, distichous leaves, and terminal globose heads of small yellow flowers. The three-lobed lip is lacinate at the margins; t. 7586.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The annual meeting of this society will take place on Monday next, March 14, at 8 P.M., at the Caledonian Hotel, W.C. Mr. GEORGE WYTHES, of Sion House, has kindly consented to preside.

"BIOGRAPHICAL INDEX OF BRITISH AND IRISH BOTANISTS."—We are glad to see that MESSRS. BRITTEN and BOULGER have commenced the publication in the *Journal of Botany* of a supplement to their Index of the names of British Botanists. The original work has proved so useful that it is very satisfactory to welcome a continuation, the more so as it will be republished as a pamphlet, and in that form readily bound up with the original work.

JOHN'S "FLOWERS OF THE FIELD."—We learn from the *Journal of Botany* that Mr. G. S. BOULGER is engaged in the preparation of a new edition of this popular book.

THE FOOD OF THE HOUSE-SPARROW.—Mr. GURNEY, of Keswick Hall, Norwich, has been making extensive investigations concerning the food of the house-sparrow during every month of the year. In summarising the results of his enquiries, he states that:—"It may be said that about 75 per cent. of an adult sparrow's food during its life is corn of some kind. The remaining 25 per cent. may be roughly divided as follows:—Seeds of weeds, 10 per cent.; green peas, 4 per cent.; beetles, 3 per cent.; caterpillars, 2 per cent.; insects which fly, 1 per cent.; other things, 5 per cent. In young sparrows, not more than 40 per cent. is corn; while about 40 per

being based on information received in reply to circulars or inquiries sent to localities of the entire United States and Canada. The report, which contains a great amount of solid information, is too long for insertion here; but relatively to the points now under consideration, the united "verdict of the entomologists," formally given, is "that there is an overwhelming mass of testimony to the effect that the sparrow drives away certain of our most valued species of native birds;" and in reply to the question on the circular, "Is it an insect-eater or a seed-eater?" every answer, based on dissection, agrees in attributing to this bird a diet almost wholly vegetable.

after deducting transit costs of from 20 to 36 marks. The senders of Grapes have to exercise the utmost care not to send Vine-leaves as packing, the Russian authorities being extremely particular in this matter owing to the Phylloxera. As a protection against the intense cold, the packets are securely wrapped in felt or woollen cloth of several thicknesses, a number of the packets being then placed together in one package and made secure. Could not our Grape-growers find an opening in this direction?

THE CHEMISTRY OF THE GARDEN.—Mr. HERBERT COUSENS has published, through Messrs. MAC-

FIG. 61.—CORDYLINÉ AUSTRALIS IN THE ABBEY GARDENS, TRESCO, SCILLY ISLES (SEE P. 152.)

cent. consists of caterpillars, and 10 per cent. of small beetles. . . . Sparrows should be killed for dissection in the afternoon. If the sparrows are caught at night, they have digested their food in a great measure." The *Agricultural Gazette* of New South Wales (whence is taken the above extract) speaks of the rapid increase of the sparrow in that colony and in America, "consequent on the ill-advised introduction by private enterprise of this bird." At a meeting, at Washington, of the Council of the American Ornithologists' Union, the committee rendered its final report of considerations as to the serviceableness or otherwise of the sparrow, these

THE RUSSIAN-WINTER FLOWER AND GRAPE TRADE.—There is a pretty lively and remunerative trade done in cut-flowers of Carnations, Roses, Violets, &c., during the early months of the year with Nice and other parts of Southern France, most of which passes through Paris *via* the German railway system to St. Petersburg and Moscow. Grapes are likewise imported to the extent of about 36,000 puds annually. A pud equals 36·38 kilogrammes. The goods are packed in wooden boxes having a gross weight of 5 kilos., or a net weight of flowers, &c., of 3 kilos. The Russian custom duty is 50 kopecks in gold per pud; and the contents of a packet sell for 50 to 60 marks—a profitable price

MILLAN, an original little primer on the subject of chemistry as applied to gardening practice. The originality consists in the treatment, for anyone looking down the table of contents would see nothing but the old headings; a further glance would show that the subjects are freshly treated, and those whose business it is to read and consult such treatises will be thankful accordingly. The desirability of establishing experimental plots on every farm is emphasised as of greater importance than mere chemical analysis. The "ash" represents only the constitution of the plant dead and cremated, it yields very little information as to the actual constitution of

particular parts of the plant during life, or at the different periods of its life. The questions relating to manures are also well treated, and the extravagance entailed in the use of many of the much-advertised manures pointed out. The author comes to the same conclusion that we did after causing a number of these manures to be analysed, viz., that they are for the most part good in their way, and free from what may be called intentional adulteration, but that their cost is prodigiously greater than it need be. The author gives in the present book several prescriptions for the formation of manures for special purposes, and which can be obtained from any druggist at a small fraction of the cost of the patent manures. The remarks on fungicides and spraying are amply worthy of perusal, and it is encouraging to learn that at last farmers and gardeners are beginning to shake off their apathy in this matter. We must give credit to the County Councils for this improvement. The exhortations of the press, as we know, effected little till the establishment of the County Councils.

LA QUESTION DE LA PROTECTION DES OISEAUX EN EUROPE.—A paper has been issued by Dr. OHSEN (Aix), considering the subject of the destruction of the rare birds, and the probable effects to agriculture and to science generally should the present system of permitting such slaughter be continued. The author proposes that:—1. An International Conference should be summoned as soon as possible for the universal protection of useful birds; 2. This international meeting should work for the protection of nesting birds and for birds near watercourses in seasons of drought; 3. There should be international legislation for the protection of migran's and birds of passage; 4. To render these conditions more easily observed, protective leagues and societies should be encouraged; 5. In elementary schools, the life-history of useful birds and the means of encouraging them should be taught; 6. The habit should be abolished of offering, during industrial exhibitions, prizes for objects destructive to bird-life, guns alone excepted; and 7. An international committee should be formed for the regulation of matters pertaining to sport (shooting) in the various districts.

GREAT ROSE SHOW AT FRANKFORT-ON-THE-MAINE.—An exhibition of Roses will be held at Frankfort-on-the-Maine, commencing in the early days of June next, and lasting, weather permitting, till October. It is the intention of the proposers to make it the finest exhibition of the kind that has ever been held. Herrn C. P. BRASCHEIM is the director of the same, and the telegraphic address is "Rosenausstellung—Frankfurtmain."

THE CARNATION SOCIETIES.—The twenty-first annual Report of the National Carnation and Picotee Society (Southern Section).—The Society starts with a balance in hand of £208 16s. 9½d.; a membership of 350. The next exhibition will be held at the Crystal Palace on Wednesday, July 20.—The Midland Carnation and Picotee Society's seventh annual Report contains a report of the show held at the Botanic Garden, Birmingham, on August 5 and 6 last, and a list of the prize-winners on that occasion. The balance-sheet shows that after payment of all expenses there remains a sum of £48 13s. 4d. to be carried forward. The next exhibition will be held in the Birmingham Botanic Garden, Edgbaston, on July 27 and 28.

STOCK-TAKING: FEBRUARY.—Considering the amount of political disquietude evinced in nearly all quarters of the globe, little surprise need be felt at the unsatisfactory state of the Board of Trade Returns for the month of February. The imports have fallen £1,474,290 below those for the month of February last year; the exports by £222,833. Thus the imports for last month were £35,770,874, against £37,245,164—hence the difference. The principal decrease is to be found in articles of food and drink, duty-free and dutiable, viz., £413,070, and in raw materials for textile fabrics, £867,921. There are

other reductions, but these explain the fall. The following is our usual excerpt from the "summary" table of imports:—

IMPORTS.	1897.	1898.	Difference.
Total value ...	£ 87,245,164	£ 35,770,874	£ —1,474,290
(A.) Articles of food and drink—duty free ...	11,860,734	11,615,507	—245,227
(B.) Articles of food and drink—dutiable ...	2,127,045	1,959,202	—167,843
Raw materials for textile manufactures ...	8,031,535	7,223,664	—867,921
Raw materials for sundry industries and manufactures ...	2,795,631	2,680,854	—114,797
(A.) Miscellaneous articles ...	1,130,623	1,226,896	+96,273
(B.) Parcel Post ..	98,243	139,180	+40,937

A large forward movement of cereals has been reported from the Far West, but this will influence the next series of Returns. Clover and grass seeds figure for £107,216; flax seed, £145,316; rape seed, £13,376; and Hops are valued at £133,769. The figures relating to fruits, roots, and vegetables are possibly the strangest we have published for years, and are as follows:—

IMPORTS.	1897.	1898.	Difference.
Fruits, raw:—			
Apples ... bush.	623,265	176,736	—446,529
Cherries
Plums	360	775	+415
Pears	3,117	2,782	—335
Grapes	1,405	795	—610
Unenumerated	39,307	49,221	+9,914
Onions	552,119	362,263	—189,856
Potatoes ... cwt.	40,793	532,483	+492,053
Vegetables, raw, unenumerated ... value	£68,514	£71,571	+£3,057

Surely such a set of minus quantities are surprising. In the case of Apples, however, the deficit is easily understood, but the wide publicity given to our selection of figures will doubtless influence exports from neighbouring sources of supply—provided there are sources to be tapped. By the way, the loss on the imports of the two months is placed at £1,320,667; that is to say, the figures for January and February in 1897 are £77,020,832, against £75,700,165 in the present year. In the matter of

EXPORTS

we find a falling off for February amounting to £222,833, accounted for thus: February, 1897, give £17,864,682 against £17,641,849 for the month just ended. The decrease is not a large one, still it is a decrease; the items of increase are to be found in living animals, raw materials, yarn and textile fabrics; keeping in view the recently-concluded engineering strike, we find that machinery and millwork show a reduction of £236,316, but this is much less than was reported last month, and we may conclude that work is once more going merrily on at the various factories. Amongst the articles of food and drink exported are ale and beer, biscuits and bread, butter, cheese, fish, Hops, pickles, preserved fruits, confectionery, meat, salt, spirits, sugar refined and candy. The deficit for the first two months of the year foots up at £777,665, thus accounted for: Two months, 1897, £37,650,918; 1898, £36,873,253. Thus ends a record we hope to find amended in April.

SEED FOODS.—Messrs. JAMES CARTER & Co., High Holborn, having long since acquired reputation for agricultural and flower-seeds, have turned their attention to those seeds which are of importance for food. They have submitted to us samples of Oats prepared in a particular way, and which form an excellent dietetic product. Their preserved butter-beans are also excellent, being more delicate in flavour than the ordinary Haricot. The feeding value of these seeds is already high, but when the horrors of famine, forecasted by Mr. MARSTON, and

some others, are upon us, the value of such productions as those of Messrs. CARTER will be largely increased, as their nutritive value is high, and a crop could be raised in a relatively short time. In the meantime the judicious consumption of these seed foods will brace us up and render us all the better able to contend against such catastrophes if they should happen!

NEW "BRITISH FLORA."—It is announced in the *Journal of Botany* that a new *British Flora*, by Rev. E. F. LINTON, is in preparation. The flora will be arranged according to the last edition of the *London Catalogue*. It is to be hoped that the compiler will be good enough to give the full synonymy, so that those to whom the works of BABINGTON, BENTHAM and HOOKER are more or less familiar, may not be utterly confused by the new nomenclature. Fresh specimens of rare or specially interesting plants may be sent to the Rev. E. F. LINTON, Crymlyn, Bournemouth.

FRUIT FROM THE CAPE.—The *Norman*, of the Union Steamship Company's line, has arrived with the second cargo of fruit from the Cape. She brought 242 boxes of Nectarines, in first-class condition, which realised good prices; 62 boxes of freestone Peaches, sold at good prices; 417 boxes of clingstone Peaches, which, for the description of fruit, realised fair prices—these latter are not considered a good sale in this market. Some 30 boxes of black Grapes, which were very small and of poor quality, were sold at only nominal prices. Pears were sent to the amount of 40 boxes, which arrived in good condition, and fair prices were realised for this, the first consignment of the season.

THE SAN JOSÉ SCALE.—We are unwilling to create needless alarm, at the same time it is our duty to warn our fruit-growers of a possible danger, against which the Canadians and some of the States of the Union have already taken action. Considering the enormous quantities of fruit imported from Canada, some of the Eastern United States, and even California, it is but too probable that the scale will make its way to this country. In California damage to the extent of millions of dollars has been effected. Within twelve years it has infested every fruit section of San José, and reached the orchards of Oregon and Washington. Evidently, says the *Canadian Horticulturist*, this pest will infest every orchard in Canada within the next ten years unless the greatest promptitude is taken to destroy it." We have already given illustrations of the insect.

ICONES BOGORIENSES.—Under this title has been published by E. J. BRILL, of Leyden, the first number of a series of illustrations of new or remarkable plants in the Buitenzorg Botanic Gardens, or in the Dutch Indies. The *Icones* are under the special direction of Dr. J. G. BOERLAGE, Assistant-Director of the Buitenzorg Garden. The publication is thus of the nature of *Hooker's Icones*, and chiefly of botanical interest. Numerous analytical details are given, and the text is in Latin and in French. Twenty-five lithographic plates of large octavo size are contained in this first fascicle.

THE ROSE OF HILDESHEM.—Those of our readers who may have visited this quiet Hanoverian town and noted its ancient cathedral, will doubtless be acquainted with the legend of the ancient Rose-tree which clammers up the massive apse of the sacred edifice. For a thousand years, so the legend goes, this Rose-tree has grown and blossomed, and now its end appears imminent, if German science cannot find an antidote for the insect or "worm" that threatens its existence. Doubtless the plant is very old for a Rose, but that it dates from the ninth century is a ridiculous myth. We gave an illustration of the plant taken from a photograph in these columns on p. 621 of the second volume for 1884.

NEW PUBLICATIONS.—*Lindenia*, special number. —*English Mechanic*.—*Canadian Horticulturist*.—*Who's Who*.—*Florists' Exchange*.—*The Chemistry of the*

Garden, by H. H. Cousens (Macmillan).—*The British Moss-Flora*, by R. Braithwaite, M.D.—*Transactions of the Scottish Horticultural Association*; twenty-first annual report.—*Botanical Gazette*, (Chicago), February 1898.—*Agricultural Journal*, Cape of Good Hope, February 3.—*Board of Park Commissioners of San Francisco*, twenty-sixth annual report for year ending June 30, 1897. A satisfactory Report, and remarkable for the "photo-chromo-lith." illustrations, which are charming for accuracy and colouring.—*Catalogue of Novelties*, E. H. Krelage & Sons, Bloemhof Nurseries, Haarlem.—*Der Gärtner und Blumenhändler*.—*Organographie der Pflanzen*, Dr. K. Goebel (Jena).—*Botanisches Centralblatt*.—*Wiener Illustrirte Garten Zeitung*.—*Compte Rendu des Travaux de la Société Nationale d'Horticulture de France*, pendant 1897, M. D. Bois.—*Statistique Horticole du Département de la Seine*, M. D. Bois.—*Bulletin de la Société Française d'Horticulture de Londres*, Année 1896. In addition to reports and notices of the Society, this includes papers on: *Cypripèdes hybrides de Veitch*, *Asparagus*, *Chrysanthèmes à l'établissement Rochford*, *Dracæna à feuillage coloré*, *Davallia*, *Établissement de MM. J. Veitch & Sons*, *Culture des Codium*, and other horticultural subjects.—*Dictionnaire pratique d'Horticulture*.—*Annales Agronomiques*, February 25.—*La Condition et les Salaires des anciens Jardiniers*, M. Georges Gibault.—*Du Role du Pseudocommis Vitis*, Debray, by M. E. Roze.

PLATYCERIUM ANGOLENSE, WELWITSCH.

THIS is a well-marked species of *Platycerium* which has lately been introduced into cultivation by Professor M. Emile Laurent, of Brussels, who spent some years in Upper Congo-land, returning last year, when he presented to Kew various plants and plant-products which he had collected there, among them being a healthy young plant of a *Platycerium*, which he said was most likely *P. angolense*, a good species, quite distinct from *P. æthiopicum*, with which it had been confused. Dr. Welwitsch collected *P. angolense* in Angola in 1855, and it is noted in Hooker and Baker's *Synopsis Filicum* as being "most like *P. æthiopicum*, but it has a broad-cuneate fertile frond, 9 inches wide at the top, without either fork or horns, and with a patch of fruit nearly as broad as the lamina." In 1870 Dr. Schweinfurth found the same species in Niam-Niam, 1500 miles north and inland from Angola, and he named it *P. elephantotis* (see *Bot. Zeit.*, 1871, 361). Mr. Baker has decided that this and *P. angolense* are identical.

The Kew plant here illustrated (fig. 62), is now in a condition to show that *P. angolense* is a distinct and handsome species, with large erect barren fronds and cuneate fertile fronds, which, as shown by dried specimens, attain a length of 18 inches, and a width of 9 inches at the top, narrowing gradually downwards to the base. The upper surface is deep green with darker veins, the lower is covered with a felt-like rust-coloured tomentum, and the sori are in a large roundish patch near the top.

As a species this differs from all other *Platycerium*, in having fertile fronds which, instead of being forked or branched, stag's-horn-like, are distinctly wedge-shaped in outline; there is also the character of the rust-coloured wool on the lower side. A batch of sporelings of *P. angolense* has been raised at Kew. W. W.

BOOK NOTICE.

THE FLORA OF BERKSHIRE. By G. C. Druce, M.A. &c. (Clarendon Press, Oxford.)

THIS is a companion volume to the excellent *Flora of the neighbouring county of Oxford*, which Mr. Druce published some few years since, and like it, is elaborated with a degree of patience and care remarkable in one who is at one and the same time a municipal dignitary, a curator of the Fielding herbarium, and a man engaged in business. More than 1,200 species are passed in review, 893 of which

are recognised as indigenous to the county. The distribution of these plants is traced in "botanical districts," arranged according to as many river-basins, but, as river-boundaries very seldom constitute any real lines of demarcation, the epithet "botanical districts" is a misnomer. A much better arrangement would have been one according to the nature of the soil, alluvium, gravel, sand, peat, loam, chalk, or what it may be, with minor sub-divisions dependent on hill and dale, field or roadside, and so forth.

Berkshire for a short part of its area confronts Oxfordshire, with the Thames between; the City of Oxford being placed in an angle where the two counties meet and share the classic Isis between them. This circumstance will recall to many an old Oxonian rambles in Bagley Wood, where the beautiful *Campanula* or *Wahlenbergia hederacea* and the elegant *Anagallis tenella* still flourish, to Cumnor where *Gagea lutea* is to be found, and rambles in the meadows still decked with *Fritillaria*.

The first plant mentioned appears under the very unfamiliar name of *Cervicina* of Delile. Mr. Druce impresses us so much with the extent of his

FIG. 62.—*PLATYCERIUM ANGOLENSE*. ($\frac{1}{6}$ nat. size.)
(Reproduced from a photograph by Mr. A. Griessen, of Kew Gardens.)

learning, and the accuracy of his research that we do not for the moment question his decision as to the fact of priority. We do, however, greatly regret that he has not followed the *Genera Plantarum* of Bentham and Hooker, and the *Index Kewensis*, rather than have disinterred a name that has been left in oblivion for more than three-quarters of a century. Now that we have an authoritative index of names, let no change, save such as a monographer may deem necessary, be made. The subject of nomenclature, however, is one upon which agreement, in spite of judicial decisions and edicts of councils, seems as far off as ever. We gladly pass it by for the sake of reverting to the author's Introduction, which supplies an admirable account of the physical geography of the county, together with lists of the characteristic plants of each formation, and of each of the so-called districts.

Then comes a "Botanologia," or catalogue of botanists who have occupied themselves with Berkshire botany, together with condensed but excellent accounts of their respective lives and doings, beginning with Turner, and ending with Dr. Arnold Lees. We caution the reader, whose time is limited, that if

he once gets immersed in the perusal of this delightful Introduction, he will find the moments slip away much faster than may be always desirable. A local *Flora* is rarely very interesting save to local botanists, but here is one which, by its Introduction and its numerous miscellaneous notes and comments, will appeal to many a botanist beyond the limit of Berkshire. Making all the necessary allowances, we may compare the impression made upon us to that made long ago by Gerard Edward Smith's *Flora of South-East Kent*, a book that, from schoolboy days, before the century had reached its middle term, till the present, has exercised a fascination over us.

THE FERNERY.

HARDY FERNS.

THE present time affords a favourable opportunity for dividing, transplanting, and generally preparing for the coming season of active growth, since all the species are now on the move, and invigorated by the winter rest, are in a condition to stand a good deal, even in the way of surgical operations, without any damage. In the open ground it may be advisable to defer operations until the middle of March, but where any glass protection is used, such as cold-houses or frames, they may well be overhauled in February, since the subsequent risk of a "cold snap" can be the better provided for. Deciduous Ferns in pots which have been plunged out of doors, should now be restored to their summer quarters, and as worms often find cosy retreats among their roots, and are not desirable tenants, it is as well to turn the plants out and do the necessary eviction, profiting by the opportunity to replace the pots by clean ones, readjusting the drainage, mulching the surface and so on, so as to give a fair start. As we have frequently pointed out, all the species which form definite crowns and send up their fronds shuttlecock-fashion, benefit greatly by being kept to a single crown, instead of being allowed to grow into bushes of numerous ones as they are apt to do if left alone. Some varieties do this so constantly that this keeping to one is impossible, and some small forms derive all their beauty from density of growth. Such, of course, must be allowed to grow on into such specimens as best befits their character, but the large growing plumose and crested varieties in most cases form offsets and divisions in such a fashion that they are easily removed as they appear, and after a time the tendency to form them diminishes and even disappears altogether, a sort of trunk being formed above the soil upon which offsets do not appear.

This sort of multiplication takes two forms, one in which the crown, at first round and symmetrical in its frond production, gradually increases in diameter in one direction, and after throwing up its fronds irregularly, develops into two independent centres of growth, each with its independent shuttlecock. In time these grow outward and apart, and so soon as this is seen to be effected, it is quite safe to insert a wedge and force them asunder, or even to sever the junction with a sharp knife, when each individual will be found to be furnished with its independent quota of roots, and only needs to be properly installed to thrive the better for the divorce, those roots having no competition to contend with. In the other form, small plants appear as bulbils on the sides, and can easily be detached and brought on in thumb-pots. Naturally these operations are attended with much less risk when the Fern fronds are conspicuous by their absence as at present, and if carefully carried out, the subsequent growth will be absolutely unaffected by the operations, beneficially drastic as they may appear in some cases. Very often in turning out a plant scarcely any roots will be found, while the soil is black and unhealthy-looking. This is usually due to over-potting the previous season, so that the root-action failed to keep the soil sweet, and subsequent fermentation, or something like it, eventually killed the bulk of the roots which had been made. In such cases, the best plan is to wash the remaining roots clean in tepid water, removing all the dead ones and any rotten portion of the caudex or rootstalk, the

growing centre of which will probably be found alive and doing its best to live, despite adversity. After such cleansing and removal of dead matter, it will in all probability revive, since the new little roots emitted by the fresh growth will not find themselves forced to penetrate a mass of soured soil in their efforts to extend. In these potting and re-potting operations a sharp look-out should be kept for weevil-grubs, as if that delightful insect, the weevil, be an unwelcome visitor, the small, fat, white, kidney-shaped grubs will frequently be found snugly ensconced in the very root-stock of a languishing plant, whose death they are slowly encompassing, while preparing themselves for an active campaign above-ground in the coming season. The presence of these vermin can often be detected by loose fronds, since they eat away the base, and the fronds fall over. Out-of-doors, the same effect is produced by the leather-coated grub of the daddy-longlegs; and there is a small dark-coloured snail, with a shiny shell (*Helix alliaria*), which gnaws them through above-ground in a very provoking fashion, and brings tears to the eyes of its destroyer with its powerful Onion-like odour. Slugs, too, apart from their devouring propensities, have a knack of laying their "pearls," or eggs resembling pearls, just inside the pots, and these, if not evicted, eventually produce a lively little brood to work havoc among the seedlings. *C. T. Dreury.*

(To be continued.)

CULTURAL MEMORANDA.

CYCLAMEN PERSICUM GIGANTEUM.

I ALWAYS believe that it is never too old to learn, and very often indeed I obtain from these pages practical hints on cultivation that far surpass older methods. The early spring is the best time for sowing *Cyclamen* seed; and the best kind of compost for filling the seed-pots or pans is one that consists of fibrous loam two parts, leaf-mould and decayed manure each one part, with silver-sand in quantity sufficing to keep the soil porous. The whole of these substances must be passed through a sieve with a $\frac{1}{2}$ -inch mesh. The pans or pots should be filled with clean crocks and some charcoal. Fill firmly to within 1 inch of the top, make level, and so thinly broadcast, and just cover the seed with soil, and no more, and over each pot, &c., put a sheet of glass, and place in a warm, moist house, shading from sunshine, but tilting the glass slightly to let moisture escape. The seedlings will appear within a fortnight; and when well above the soil, remove the glass, but afford shade. When large enough, lift very carefully, and pot into 60's; pot firm, and keep the corms just above the surface, using a mixture of the same compost as before stated. Always put good drainage. Grow on in an ordinary greenhouse on a shelf close to the glass, and well shaded.

Place the plants when well established, about the second week in June, in a cold frame, raising them near the glass, shading them and affording plenty of air, the lights being pulled off at night in fine weather. When the pots are filled with roots shift into 48's, mixing a small quantity of artificial manure with the soil, and when well established afford liquid manure twice a week, finally shifting them into the greenhouse. When the flower-buds appear, examine closely for thrip, and if any are seen apply tobacco-powder. After flowering, rest the plants in a cold frame, and in August shake the tubers out of the soil, cut off decayed roots, and repot into 48's, the largest bulbs into 32's, and grow on as before recommended for seedlings. *J. S.*

MARKET GARDENING.

FLOWERS IN THE OPEN.

A GOOD selection of cut flowers of both perennials and annuals commands a ready sale, and remunerative wholesale prices during the summer and early autumn months, in all large town and popular seaside places

of resort. Flowers of substance and distinct colours, and cut with a good length of stem, find most favour with the general public, and these should, as a matter of course, be grown in quantity.

The *Alstroemeria* is a beautiful class of tuberous-rooted hardy plant, producing flowers of great brilliancy of distinct and pleasing shades of colour, and which are invaluable for cutting. *A. aurea* produces very showy bright orange-coloured flowers in umbels; *A. chilensis* is a dwarf-growing species, and sends up immense heads of bloom, varying in shades of white, lilac, rose, salmon, &c.; *A. pulchella*, large heads of white flowers, striped red; *A. psittacina*, dark crimson, splashed with mahogany, height 3 feet; *A. pelegriana*, large heads of purple flowers, beautifully striped; *A. peregrina alba*, umbels of snow-white flowers; this and the preceding one should be afforded a dry, sunny situation. *A. peruviana* produces large heads of crimson flowers; and *A. tricolor* yields a profusion of white flowers which are effectively striped with crimson and yellow. The above-mentioned plants will succeed in any herbaceous border in which the soil is light rather than heavy, and of average fertility and depth.

Large quantities of *Alstroemerias* are grown for supplying wholesale florists in Covent Garden. *Anthericum*, *Aquilegia*, *Coreopsis*, *Delphinium*, *Doronicum*, *Geum coccinea plenum*, *Helenium*, *Pyrethrum*, *Hesperis matronalis alba-plena*, *Heuchera sanguinea*, *Francoa ramosa*, *Gypsophila paniculata*, *Rudbeckia Newmanni*, *Scabiosa caucasica*, *Spiraea Aruncus*, *Astilboides floribunda*, and *Thalictrum adiantifolium*, are all suitable perennial plants to grow for supplying the cut-flower trade, and the present is a good time for transplanting and making new plantations of them in soil of the description indicated above, and, if possible, in situations which are sheltered from the north and east winds.

Bulbous plants, such as double Daffodils, Snow-drops, English and Spanish Irises, planted a few inches apart in beds or borders, in holes 3 or 4 inches deep, yield good returns in due time; the only expense attached to the culture of these plants after the initial cost of bulbs and planting, being that incurred in the gathering and bunching of the flowers, and the sending of them to retail and wholesale florists; the bulbs annually increasing in size and floriferousness, an occasional manurial top-dressing of the ground helping in this direction. *Lilium candidum* (the white garden Lily), and the several sections of the *Gladiolus* are also in demand during the summer and autumn months. Good plantings of the ever-popular Lily of the Valley made in good rich lightish soil, both in sunny and shady situations, always command a ready and remunerative sale. Like kindred subjects, hardy perennial plants (of which those included in the brief list given above, are among the best for marketing) pay for generous treatment in the way of having a good dressing of short light manure dug into land set apart for them, and which require being thus enriched.

Annuals include many charming and valuable kinds of flowers for cutting purposes, and which realise a ready sale, and satisfactory wholesale prices. Foremost among these are Sweet Peas, Mignonette, Cornflower (*Cyanus Blue Victoria*), summer-flowering *Chrysanthemums*, Stocks, and Asters. No time should be lost in making a good sowing of Sweet Peas of the following varieties:—Queen of England (fine white), Scarlet Invincible (bright scarlet), Dorothy Tennant (dark mauve), Captain of the Blues (large blue), and Mrs. Eckford (fine primrose). Sow the Peas somewhat thinly in drills, about 2 inches deep, and from 3 to 3½ feet asunder, in ground which has had a good coating of short manure dug into it, closing the soil in over the seed with the feet. The seed may be drilled in with a machine, where large sowings are made, the drills preferably running north and south. Good sowings should also be made in shallow drills running in the same direction of Cornflower and Mignonette, allowing a space of 18 inches between the rows, sowing the seed very thinly therein, and covering it lightly with the soil drawn out in forming the drills. Stocks and

Asters should be raised in heat; or where this is not available, the seed may be sown in a warm corner out-of-doors, and covered with a few squares of glass, the soil being drawn up a couple of inches outside the space whereon the seed is sown, to rest the glass on. When the plants thus raised are large enough to handle, they should be pricked out a couple of inches apart in a like position, preparatory to transplanting them into good enriched soil, 1 foot apart every way in due time, care being exercised in the matter of watering and airing the little plants in the meantime. *H. W. Ward, Rayleigh.*

LATE - KEEPING DESSERT APPLES.

AMONG the varieties of dessert Apples, which are good eating after the end of the year, a high flavoured one that might be classed as a late Cox's Orange Pippin is still lacking, and the raiser of one that would, under ordinary conditions, remain good till March and April, or May, would be well rewarded, provided the tree was a good cropper. Fruits of Cox's Orange Pippin may, in well-constructed fruit-rooms, be had in good condition till the present date, and later if they are not gathered very early; but it may be accepted as a pretty general fact that the end of the month of December is as late as the fruit is found in most gardens. Blenheim Orange, is a favourite fruit with many, and it has passed its best at about the same time. Adams' Pearmain is one of the best January Apples, the flavour of fruit taken from trees on rather light soils almost equalling that of Cox's Orange Pippin. The tree is, moreover, a good and regular cropper, the fruits of even size, fully up to dessert standard, and in open situations the colour is a bright crimson. This variety succeeds admirably as a standard on the Crab, or as a bush on the Paradise stock. Cockle Pippin is another old variety, the fruit of which keeps good till the New Year. It is of middle-size, and of a spicy flavour. The outward appearance of the fruits, however, is not attractive like those of the preceding variety being generally of a greenish or lemon-yellow, and, irregular in outline.

Claygate Pearmain, which I was pleased to see awarded a prize in the flavour competition at the January meeting of the Royal Horticultural Society, is one of our favourite Apples. It is in use in January and February, and in some years later. When grown on orchard-trees it acquires a brisk, Ribston Pippin flavour, but has a softer flesh. It is a Pearmain in shape, and its colour when ripe is russety-lemon-yellow, streaked with red on the exposed side, and in size it is fully up to the usual standard of a dessert Apple. This does not generally appear to be grown to the extent it deserves for its regular cropping qualities.

Golden Reinette is another good-keeping variety of excellent flavour and colour, but the fruits being rather small, it is now not much cultivated. Hubbard's Pearmain is another that suffers through being slightly under-sized. The fruit keeps in good condition well into March, and attains a rich colour when ripe, the yellow flesh being firm and of very good flavour. This is usually a fine cropper as a standard tree on the Crab, but was a failure this last season. Fearn's Pippin, although not of first quality, is highly coloured, and keeps well. Dutch Mignonne, recognised by the Royal Horticultural Society in their select list as a dessert variety, keeps firm to the end of March, and the trees crop regularly. Several orchard standards here have for the past ten years never failed to produce a crop, at times too heavy a one. Selected fruits are very useful for dessert oftentimes at this season, although it seems properly a culinary variety, being an admirable cooker. Wyken Pippin is an old variety that keeps into March, sometimes later, it appears to flourish best in the west and midland districts, and is said to be a favourite Apple in the Birmingham markets. Court Pendu Plat is an excellent late-keeping Apple of moderate size. This variety is, moreover, a very constant and regular cropper, and bears well when grown as a standard in orchard or bush form. It is one of the latest varieties to open its blossoms in

the spring, and from this circumstance sometimes escapes frosts, which destroys that of earlier-blooming kinds. If asked to mention the best late-keeping dessert Apple, I should unhesitatingly say it is Sturmer Pippin, which, taken on all points, I think cannot be beaten by existing varieties. Grown either as an orchard standard, or in bush form, it invariably crops well: the fruits are of good dessert-size, flesh firm, and flavour good, with a slight likeness to Ribston in it. When ripe it attains a golden-russet colour, with a bronzy-red cheek on the exposed or sunny side, and it may be kept in good condition quite to the end of May. The longer it is left hanging on the trees in autumn, the better are its keeping qualities; and unless very bad weather sets in, this variety should never be gathered until quite the end of October. In selecting six varieties from those above-mentioned in their order of ripening, I should give Cox's Orange Pippin, Adams' Pearmain, Claygate Pearmain, Hubbard's Pearmain, Court Pendu Plat, and Sturmer Pippin. *C. Herrin, Dropmore.*

HOME CORRESPONDENCE.

NEW SPECIES OF TREES SUCCEEDING CONIFER FORESTS.—I saw some remarks in your "Answers to Correspondents" on February 19 respecting hardwood trees succeeding Coniferous forests which have been burnt. There certainly is a natural tendency for forests of one species to be followed by one of some other species, at least sometimes. In Denmark in prehistoric times forests of Pine have been succeeded by Oak and Beech forests. At Boynton, a wood of large Silver Firs was blown down in the great gale on January 7, 1839. The whole wood came up thick with young Silvers, which are now well-grown trees, 9 to 15 inches in diameter. No seedling Silvers will now grow in the wood. They come up sometimes, but never grow for more than three or four years. The wood is full now of seedling Ash and Sycamore. Of course some woods, like the Beech woods of Buckinghamshire, go on growing from seed without limit; but I believe in a succession of crops occasionally applying to trees as to other plants. *C. W. Strickland.*

APPLE DUMELOW'S SEEDLING.—There is little to add to the interesting history of this fine Apple given by Mr. R. Dean on p. 141. I never heard a good reason for one of its most popular names in East Anglia, Dumeller's (Dumelow's) Crab. True, the flesh is firm, crisp, brisk, juicy, but it is rather aromatic than acid, and no Apple grown can well be a more perfect cooker. Sousing Apple is another of its synonyms. This Apple is also known by other names, such as Lord Hampton's Wonder, Lord Duncan, and Fair Maid of Taunton. It was only a few years since, when lecturing on technical education for the Cambridge County Council, that I made full acquaintance of the commercial value and superb quality of this valuable and profitable Apple. Mr. Elliotson, of Bassingborne, Cambs, called me in to consult about his Apple-orchard, partially furnished with very healthy trees of this fine sort. They had grown so fast and fruited so little, that he had become weary of waiting for the fruit, and he was anxious to head them, and work his Dumelows with Blenheim Orange or Cox's Orange Pippin. My advice was an emphatic "No; leave them alone another year or two." I claim no credit for the advice, for the signs of the coming harvest of fertility were already visible to all who could read them. Next autumn I was invited to see the harvest in store. I shall never forget it. It amounted to several thousands of bushels, and the fruits were of high quality. The fruit you figured on p. 141 last week was a sample of the crop, painted by my wife. Dumelow's Seedling on the Crab is a vigorous grower, and if fed freely will sow its crops of wild oats in the form of timber for several years; but root-prune or starve the trees into a full crop, and fertility will repeat itself as certainly as among other sorts. On the Paradise or other surface-rooting stocks the variety fruits freely, earlier, and with yet greater constancy than on the Crab. Its high keeping qualities are equal to its almost perfect cooking properties, and its season extends from November to April. We have few or no culinary Apples that command higher prices through December, January, February, and March. In the prosecution of fruit-culture we hear much of the importance of ear-marking certain things for these and kindred purposes. Such varieties of the Apple as

Dumelow's Seedling, when carefully noted as to eye, flesh, skin, stalk, and wood, mark themselves as a security against mistaken identity. The eye is large and open, with broad reflexed segments, set in an irregular, uneven, and fairly deep basin; flesh yellowish-white, firm, crisp, brisk, and very juicy, with an aromatic flavour; skin pale yellow, strewed with large, irregular russet patches or points, with a tinge of red next the sun, occasionally, though rarely, converting the unusually semi-blanching fruit into a bright red checked beauty, shining as if varnished over; the stalk is about half an inch long, deeply inserted in a narrow and funnel-shaped cavity, lined with russet; the wood, especially the long and stout shoots, is thickly covered with large, grayish-white dots, which readily distinguish the kind. Its very substantial merits and its numerous synonyms give special force and point to the advice, that when you ask for the Wellington Apple, see that you get it true, and return or destroy all spurious imitations. *D. T. Fish, 12, Tettes Row, Edinburgh.* [We owe an apology to Mr. Fish for omitting to indicate the source of the excellent illustration last week. *Ed.*]

—Undoubtedly this is one of our very best late Apples, and is a great favourite with the cook; in fact, I have as yet never heard of a single complaint respecting the Wellington, as it is generally named. It is a variety that on cold soils and in cold districts requires a warm autumn to ripen its fruits thoroughly; and then it will keep till the month of May. The fruits, in some seasons, become somewhat spotty, and decay rapidly, especially in damp fruit-rooms. The flesh is crisp and full of juice. It is a variety which is very extensively grown in some parts, and although the trees grow and fruit well in some orchards and gardens, it is at the same time attacked by canker. The fruit in certain soils in the south become as red as those of Bauman's Red Reinette. *H. M.*

ROYAL GARDENERS' ORPHAN FUND.—Seeing your report of the meeting of the Gardeners' Orphan Fund in the *Gardeners' Chronicle* of February 26, I cannot help thinking, on the one hand, how much we, who have its interest at heart, have to be thankful for, especially to our committees, past and present, also to our good Secretary, for the able way in which they have used the money entrusted to them, and for the untiring labour they have given for the benefit of others. Then, again, there are those who have helped us with large sums of money, knowing that they themselves can in no way reap benefit for the same; but, on the other hand, how little we have to thank the gardeners of Great Britain, a body who seem to forget that in helping this Fund [and that of the Gardeners' Benevolent] they are helping themselves, or their survivors, and the consequence of this forgetfulness is, that certainly not one-tenth of them subscribe. I wonder if they have ever thought what the annual income would be if every one, gardeners, foremen, and journeymen, would subscribe one penny a week? I think if they would sit down and work this out, the result would not only surprise them, but it would, I believe, nerve them on to the effort, and with that income secured, many more children would be enjoying help, which now has to be carefully harvested, and the funded property would be increased each year. *Charles Penny.*

POTATO SYON HOUSE PROLIFIC.—Those who are in want of a late main crop Potato, which can be well recommended in every way, cannot do better than to add this new variety to their collection. I tested it thoroughly as a cropper on light soil last year, and it turned out extremely well. The variety is exceptionally free from disease, and keeps green for weeks after that of all other varieties had become black or withered, and I have not found a diseased tuber. From October onwards, the tubers are floury and of good flavour; and its present appearance leads one to expect that it will keep good as long as old Potatoes are needed. The tubers are smooth, handsome, pebble-shaped, with shallow eyes, and if they have a fault, it is that they are inclined to be too large for ordinary culinary uses when grown in very rich soil, but as a field Potato it should take a leading position among late varieties. *J. C. Tallack.*

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION'S ELECTIONS.—Your correspondent "An old subscriber," p. 141, and some others, seem to have lost sight of the name and purposes of the Institution, and seem to confound it with the intention and uses of an ordinary benefit society. I think that the Institution as at present worked by the Committee of Management, who annually select a certain number of old subscribers, and leave the general body of applicants to the natural course of benevolence,

adopt a wise and sound principle, as then I think the quality of benevolence, as Shakespeare said of Mercy, "it is twiced blessed to him who gives his votes, than to him who receives." I conned the list of applicants, and selected the oldest persons who had tried to get elected the greatest number of times, and divided my votes among three of them, and, in racing parlance, I had the satisfaction of "spotting three winners." I quite agree with some of your correspondents, notably our friend Mr. Crump, as to the desirability of canvassing gardeners who are in a position to become annual subscribers, and it is an open question, if a small annual grant from the funds of the Gardeners' Royal Benevolent to a few gardeners of good standing of the stamp of Mr. Crump, advanced as travelling expenses during their usual autumn holiday, would not be money well laid out in the interest of the Institution. *R. M. Newbury, Mar. 5, 1898.*

USELESS MULTIPLICATION OF NAMES.—I have three Hyacinths purchased as bulbs from the same grower, under the names of Queen of England, alba maxima, and La Grandesse. They have been treated in exactly the same way, in the same sized pots, in the same soil, and under the same conditions throughout. All three flowered at exactly the same time. All three are single, and of a pure white, very beautiful, with an immense head of fine bells. But in spite of their having been given three distinct names, I cannot trace the slightest difference between them. For all that one can see, they might have been offshoots from the one bulb. One can quite understand that had they been treated differently, they might possibly have shown differences; but in this case, all three were treated identically. Yet although they have been given distinct euphonious and grand names, they show no difference that I can trace, either in colour, shape, size, or time of flowering. If the Royal Horticultural Society could see its way towards discouraging this useless multiplication of names, to the bewilderment of purchasers, it would do a service to scientific horticulture. The only object which seems to be served by it is the expansion of the lists of names in catalogues, which are already far too numerous. *E. Bonavia, M.D.*

GOOSEBERRY-APPLE.—This is a favourite with some of us as a late culinary variety. In fact, I know of no Apple that will keep better; and the tree bears freely. If the fruits are quite mature when gathered, and kept in a cool room or cellar, they will be sound in May and June, and sometimes, indeed, till fresh Apples are fit for use. It is a variety that is very commonly grown in some parts of Kent. *H. Markham.*

GARDENIA CULTURE.—Your correspondent's instructive article on p. 134 has induced me to appeal to him for further information. I have almost ceased to attempt to cultivate Gardenias, owing to canker. Whether in pots or planted out, this disease invariably attacks the plants, and limb after limb is killed, until the plant dies. Occasionally the plant is attacked at the ground-level, and the plant collapses. I have tried various soils, but to no purpose. Freshly-introduced plants usually grow very vigorously, and produce dark-coloured, healthy foliage, but they rarely remain so more than six months. They receive ordinary cultivation, with stove temperature, and during summer both shade and ventilation. Thinking the disease might be contagious, I have not permitted any plants to be placed in the house (an old Pine-stove) for two years past. I now contemplate trying them again in the same house, commencing with a fresh stock. Can your correspondent, "J.," account for the virulence of the disease here, and give any cultural hints that might prevent a recurrence? Are the 6-feet high plants already mentioned shaded at all in summer? and are they given more air than stove-plants usually receive? Is it likely that I have grown the plants too quickly, and that they, being soft, were more susceptible to disease? *J. E.*

STRAWBERRIES GROWN IN A BARREL.—While paying a visit to a friend in Oxfordshire last autumn, I had the pleasure of seeing the novel way of growing Strawberries in a barrel, precisely similar to that given in the note on p. 140 of the *Gardeners' Chronicle*, and upon making inquiries I was informed the plants had given satisfaction. I was struck with the novelty of the idea. I am trying the experiment myself this season with one barrel planted with Royal Sovereign, and I will tell you later what success, if any, that I have with the plants. [Pray do. *Ed.*] *H. G. Blizzard, Mottram, Cheshire.*

SOCIETIES.

ROYAL HORTICULTURAL.

MARCH 8.—The third meeting of the Committees of the Royal Horticultural Society for the year was held on Tuesday last in the Drill Hall, James Street, Westminster. We had scarcely anticipated such a fine display of exhibits as was made, for, notwithstanding the excessively cold weather, the Hall was well filled with a very miscellaneous and bright exhibition. Orchids were by no means inconspicuous, and, as will be seen from the report given below, a larger number of certificates were awarded by this committee than the others combined. Four large trade exhibits of Cyclamens, and a smaller one also from Brussels, afforded a wealth of bloom, and were a prominent characteristic of the meeting. Those from Belgium were interesting as illustrations of a series of modifications that is taking place in the flowers of this plant under high cultivation, and they suggest that "strains" of Cyclamens may become as varied even as those of the popular Chinese Primula. Messrs. VEITCH demonstrated the beauty of a variety of the double-flowered Cherry as a pot plant for conservatory decoration. Some very pretty Azaleas (Mollis \times sinensis), were shown by Messrs. R. & G. CUTHBERT. Hippeastrums from Captain HOLFORD, and Messrs. VEITCH & SONS included several good novelties, and a variety in either group was recommended an Award of Merit. Groups of miscellaneous plants were shown in several instances, and a botanical certificate was recommended by the Floral Committee to Bryophyllum calycinum, a panicle of which was shown from the Horticultural College, Holmes Chapel, Cheshire.

A number of Daffodils was shown, and of hardy flowers a few species, including Irises, Scillas, Chionodoxas, &c., but the recent cold winds have caused a severe check to growth of all kinds out of doors. The Fruit Committee recommended the award of a First class Certificate to Cucumber Every Day shown by Mr. O. THOMAS, The Royal Gardens, Frogmore. In the afternoon a discourse upon some of the plants exhibited was given by the Rev. Geo. HENSLOW, F.R.S., being the first delivered by Mr. HENSLOW since the Council have announced his appointment as Professor of Botany to the Society.

Floral Committee.

Present: W. Marshall, Esq., Chairman; and Messrs. John Fraser, Owen Thomas, J. T. Bennett-Poë, H. B. May, R. Dean, J. H. Fitt, Geo. Stevens, Wm. Howe, J. Hudson, J. Jennings, C. J. Salter, R. B. Lowe, H. Selfe-Leonard, J. Fraser, W. Bain, Chas. Jeffries, J. D. Pawle, Geo. Gordon, Chas. E. Shea, Rev. Geo. Engleheart, Jas. Walker, J. W. Barr, E. T. Cook, H. J. Cuthbert, Harry Turner, Chas. E. Pearson, H. J. Jones, and Geo. Paul.

Choice Ferns of the more popular genera were shown by Messrs. J. HILL & SONS, Barrowfield Nursery, Lower Edmonth. Some of the larger specimens were suspended, and the group was faced by a number of baskets containing 3-inch pots, each holding a perfect little plant of one or another species. Adiantum rhodophyllum and other distinct varieties of this indispensable genus were capital (Silver-gilt Flora Medal).

Messrs. W. CUTHBERT & SON, Highgate, London, N., contributed a group of various flowering plants, chief among which we noticed a few plants in flower of Richardia Elliotiana, and some of the species of hard-wooded greenhouse plants that gardeners still grow in more or less degree—Epacris The Premier, Mrs. Pym, and Mont Blanc, and the pretty double-flowered onosmaeflora, Boronia megastigma, Ericas in several varieties, Acacias Drummondii, and cordata. A few plants of Otakeite Orange, well fruited, were included.

Messrs. W. BALCHIN & SONS, Hassocks' Gate Nurseries, showed a dozen and a half plants of Boronia megastigma, perfect specimens of culture, and fragrant as beautiful. A group of plants of Tetratheca ericoides from the same establishment was very praiseworthy also.

Messrs. JOHN LAING & SONS, Forest Hill Nurseries, S.E., had a group of miscellaneous plants, inclusive of some choice specimens with ornamental-foliage species. Dracaenas, Acacias, Ericas, Cliveias, and the first Caladiums of the season were noticed, the group being further brightened by a few Orchids in flower (Bronze Banksian Medal).

Clematises in a group were shown by Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonth. In 5-inch pots the plants had produced a quantity of flowers, and the varieties were Lady Londesborough, pale mauve; Fair Rosamond, white; Sir Garnet Wolseley, purple; Miss Bateman, white; and Mrs. Quilter, also white (Silver Banksian Medal).

Messrs. T. CRIPPS & SONS, Tunbridge Wells Nurseries, exhibited a small group of plants of Deutzia Lemoinei, that well portrayed this useful flowering-plant; and a few plants also of Deutzia parviflora \times .

A few Irises in pots were shown by Messrs. R. WALLACE & CO., Kilnfield Gardens, Colchester—Iris alata, reticulata, orchoides, sindjarensis, persica, &c.; also several varieties of Muscari.

Mr. GEO. MOUNT'S Roses were delightful. Twenty-four blooms of Catherine Mermet, and single flowers of a large number of other varieties, were as fresh and beautiful as could be expected in summer (Silver Flora Medal).

An excellent collection of Cyclamens was shown by the ST. GEORGE'S NURSERY COMPANY, Hanwell, W. The plants

were beautiful specimens of the finest florists' type possible. The colours, too, were decidedly good, and the flowers large and of rare substance (Silver Banksian Medal).

Cyclamens from the CHURCH ROAD NURSERY COMPANY carried a greater number of leaves, and smaller; and, though the flowers were not quite so good as those already noticed, the collection was a praiseworthy one (Bronze Flora Medal).

The Cyclamens shown by L. P. DE LANGHE-VERVAENE, 150, Rue de Constantinople, Saint Gilles, Bruxelles, were very remarkable. Most of the plants represented a strain of frilled, crested, and variously modified flowers that the same firm exhibited in the Drill Hall last year. As might be expected, however, the modifications are more pronounced than then. About twenty plants were shown, and the colours are almost as various as in collections of normal types.

Mr. JNO. MAY, St. Margaret's, Twickenham, also made a fine show with Cyclamens, some of which were remarkable for distinct colour, and the plants generally had been well cultivated (Silver Flora Medal).

Mr. CHAS. TURNER, Royal Nurseries, Slough, who always exhibits florists' flowers in good style, had a collection of Cyclamens that was commendable.

A pretty group of spring-flowering greenhouse and other plants from Messrs. PEED & SONS, Roupell Park Nurseries, Norwood Road, London, S.E., included numerous Cliveias, Azaleas of the Mollis section, Narcissus, Staphyleas, Primulas, &c.

Mr. T. S. WARE, Hale Farm Nurseries, Tottenham, London, made a display of Narcissus in pots. A considerable number of varieties were thus shown—Empress, Golden Spur, Princeps, Henry Irving, and others. Victoria, the new one of last season, is said to force capitally. A number of choice hardy flowers was also shown, including the pretty yellow-flowered Adonis amurensis, Ophrys aranifera, Anemone pulsatilla, Tulipa violacea, Erythronium Dens-canis, several Irises, Sisyrinchium grandiflorum, &c.

Messrs. BARR & SONS, King Street, Covent Garden, showed a few of the earlier spring flowers, including Helleborus in a few varieties, also Chionodoxas sardensis, gigantea, and Lucilia; Scillas sibirica, S. s. taurica, some varieties of Crocus, Narcissus J. G. Baker, N. cyclamineus, N. minimus, and other species.

MRS. NEWALL, Ferndene, Gateshead-on-Tyne (gr., Mr. W. Hay), exhibited a flowering spray of Rhododendron argenteum.

Messrs. JNO. LAING & SONS, Forest Hill Nurseries, London, S.E., showed plants of a semi-double, pink-flowered Azalea named dianthiflora.

Seedling varieties of Azaleas (Azalea mollis \times sinensis), from Messrs. R. & G. CUTHBERT, Southgate, Middlesex, composed a floral picture of very many shades, but all of them are pretty. A few had names attached to them such as Madame C. Legrelle, D. Harris, Alphonse Lavallée, W. E. Gumbleton, (creamy yellow with darker spotting), Comte de Gomer, &c. These were the most distinct, but the others are equally pretty (Silver Banksian Medal). Messrs. R. & G. CUTHBERT exhibited plants of Azalea Yodogama, a semi-double, lilac-flowered Japanese variety.

A few new Hippeastrums from Captain HOLFORD, Westons-birt, Tetbury, Gloucester (gr., Mr. A. Chapman), exhibited very fine merit. Fine dark crim on varieties were Stromboli, Princess Henia, and Lucania, and a few of the lighter pencilled-flowered sorts were good. An Award of Merit was recommended to the variety Princess Osra, a very large flower, colour scarlet, each segment possessing a band of white in centre.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, showed a group of Hippeastrums, inclusive of a number of new varieties of merit. An award was made to Navala, a rather large flower approaching cup shape, segments very much rounded, bright red in colour, with green base, spike as shown uncommonly short. A group of young plants of a double-flowering Cherry (Cerasus pseudo-Cerasus, Waterer's var.) attracted considerable attention. They were profusely flowered, and the pretty tints of the floral trusses are most effective. For conservatory-decoration no plant could be more desirable. A few plants of Prunus sinensis fl.-pl. in flower accompanied the above (Silver Banksian Medal).

An Award of Merit was recommended to Azalea grandiflora alba, a large-flowered greenhouse variety shown by the ST. GEORGE'S NURSERY CO., Hanwell, W.

Sir T. LAWRENCE, Bart., Burford, Dorking (gr., Mr. Bain), exhibited two varieties of Azaleodendron \times , named respectively Jules Closos and Dr. Masters. These crosses from ordinary spotted Rhododendrons and Azalea mollis were shown at the last quinquennial exhibition at Ghent by M. PYNAERT, and were fully described, with others, in an article published in the *Gardeners' Chronicle*, June 3, 1893, p. 666. The flowers of both varieties shown at the Drill Hall exhibit the spotting obtained from the Rhododendron, the variety Dr. Masters having rosy-lilac coloured flowers, and those of Jules Closos paler, being almost white, flushed with rose. We have seen no evidence at present that the plants are sufficiently good growers to become popular in gardens, Sir T. LAWRENCE also showed plants of Pavonia intermedia kermesina bearing very fine intensely crimson flowers.

From M. C. G. VAN TUBERGEN, Haarlem, came blooms of Galanthus Fosteri, and spikes of flowers of Lachenalia pendula, variety named Aureliana.

A Cultural Commendation was made to W. C. WALKER, Esq., Percy Lodge, Winchmore Hill, London (gr., Mr. Geo. Cragg), who exhibited a finely grown plant of Hippeastrum, Walker's Crimson, which had two extra strong spikes bearing about a dozen large flowers.

P. PURNELL, Esq., The Woodlands, Streatham Hill, exhibited a group of Narcissus in pots, chiefly of the "trumpet"

and cup sections; also a few hardy plants in flower, among which we noticed the curiously coloured Iris persica (Silver Banksian Medal).

A Silver-gilt Flora Medal was deservedly awarded to Messrs. W. PAUL & SONS, Waltham Cross Nurseries, Herts, who again staged a magnificent group of Camellias, including flowering-plants and cut blooms of a large number of choice varieties. The group was gayer even than that shown a month ago from the same establishment.

Bryophyllum calycinum shown by Mr. W. NIELD, Horticultural College, Holmes Chapel, Cheshire, was recommended a Botanical Certificate. This curious member of Crassulaceae was introduced from India early in the present century. It has thick, fleshy, opposite leaves, ovate, and crenate, with one or two segments. The plant may be propagated by the leaves similarly to Begonias, in this case the young plants springing from the notches in the margins of the leaves. The long cupped flowers are produced in a terminal panicle, and are yellowish-red in colour. The plant is generally grown in the stove.

Orchid Committee.

Present: Harry J. Veitch, in the chair; and Messrs. J. O'Brien (Hon. Sec.), De B. Crawshaw, H. M. Pollett, H. Ballantine, N. C. Cookson, H. Little, H. J. Chapman, J. F. Thorne, F. Sander, C. Winn, W. H. Young, W. H. White, W. H. Protheroe, S. Courtauld, E. Ashworth, J. Jaques, E. Hill, T. W. Bond, T. B. Haywood, J. Douglas, A. H. Smees, and T. Statter.

Notwithstanding the very cold east wind blowing, there, was a fine show of Orchids in flower, many of which came long distances.

Messrs. J. VEITCH & SONS, Royal Exotic Nursery, Chelsea showed a fine group, for which a Silver Banksian Medal was awarded. It was especially interesting by reason of the number of fine hybrids included, and in many cases the parents of the plants were likewise shown. Noteworthy among these novelties was a batch of crosses from Epidendrum Endresii, pollinated with other species of Orchids, viz., E. Endresii, E. Wallisii, E. \times Endresio-Wallisii, and E. \times elegantulum, all of them showing much variation. Another such subject was Epiphronitis \times Veitchii, and beside it its parents, Epidendrum radicans and Sophronitis grandiflora; the same rule applied to Cymbidium \times eburneolum; plants in bloom of Cymbidium eburneum and C. Lowianum being placed alongside.

Among remarkable hybrids was the second acquisition of Phalaenopsis \times John Seden (P. Luddemanniana \times P. amabilis, Bl.). Two plants were flowered a few years ago, and received a First-class Certificate. The one now in flower was raised from seed sown in 1891. The handsome flower has sepals and petals of a blush-white tint, profusely and evenly spotted with crimson; the bases of the segments, and especially of the petals, are a bright rose hue. The side-lobes of the lip are rose-coloured, spotted with red, and tinged with bronzy-yellow. The middle lobe of the same is of a yellowish-bronzy hue in the centre, and rose-coloured at the apex. Another fine new hybrid was Cattleya \times Miranda (amethystoglossa \times Trianaei), with flowers of good size, and of a delicate rose colour, the tips of the petals and the front of the lip of a fine claret crimson (Award of Merit). Also in the group were the brilliant Epidendrum \times O'Brienianum superbum, with bunches of dark blood-red flowers; a very showy collection of Dendrobiums, with varieties of D. Wardianum and D. crassinode at the back, and pretty yellow-tinted D. \times Wiganiae, the singular D. \times Statius, D. Hildebrandii albescent, D. \times Cybele, and the numerous fine forms of the D. \times splendidissimum grandiflorum class in the foreground. Other plants in flower were the charming pale yellow Lælio-Cattleya \times Myra, some interesting hybrid Cypripediums, Platyclinis glumacea, Miltonia Roezlii, Trichopilia suavis, varieties of Cattleya Trianaei, &c.

Baron Sir H. SCHRODER, The Dell, Staines (gr., Mr. H. Ballantine), again showed the magnificent Odontoglossum crispum "Baroness Schroder," the richest in colour of any known crispum. The flowers had attained perfect form, their surface being of a rich claret-crimson, with silvery-white showing between the large and closely-set blotches. As an extraordinary exhibit, the committee recommended that a Gold Medal be awarded. Baron Schroder also showed grand spikes of his noble hybrid Calanthe \times "Baron Schroder," and its varieties, "superba" and "delicata;" two fine spikes of Odontoglossum coronarium brevifolium, the singular hybrid, O. Cookianum; the pale yellow O. luteo-purpureum Amesianum, the distinct O. Pescatorei melano-centrum, O. Coradinei, and other Odontoglossums, for all of which "Cultural commendation" was given.

N. C. COOKSON, Esq., Oakwood, Wylam, Northumberland (gr., Mr. Wm. Murray), showed Dendrobium \times Cybele, Oakwood var. (Findlayanum \times nobile Burfordiense). The peculiarity of D. n. Burfordiense is that it shows streaks of purple and other traces of the labellum, in the lower sepals. This characteristic was transferred to the hybrid in a marked degree. Also the handsome Dendrobium \times Astrea superba (luteolum \times crassinode), the original of which had been previously shown and certificated.

Sir TREVOR LAWRENCE, Bart., Burford, Dorking (gr., Mr. W. H. White), showed the handsome Dendrobium \times Clio (splendidissimum grandiflorum \times Wardianum), and D. \times Euterpe (nobile \times Wardianum), both fine hybrids, showing much of the beauty of D. Wardianum.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. Aldous), showed Odontoglossum \times Wilckeianum Pittii, with a magnificent inflorescence, the flowers being the largest and most richly coloured of any of the forms of O. \times Wilckeianum,

and most like the grand O × W. Queen Empress in BARON SCHRODER'S collection (First-class Certificate).

C. J. LUCAS, Esq., Warnham Court, Horsham (gr., Mr. Duncan) showed *Lælio-Cattleya* × *Warnhamensis* (cinnabarina × ?) with flowers of L. C. Hippolyta class, but with the whole of the segments heavily tinged with claret colour, the yellow ground appearing at the edges and between the veining. It is a very fine hybrid. (Award of Merit).

MESSRS. J. CHARLESWORTH & Co., Heaton, Bradford, showed thirty plants of the handsome new Phaius × Norman (*Sanderianus* × *tuberculosis*) raised by N. C. COOKSON, Esq., finely flowered and showing a considerable advance upon P. × Cooksoni, a plant of which was shown with them. The plants showed great variety in their soft and rich marking, and three were selected to go before the committee for adjudication. Of these, P. × Norman had large flowers of a delicate rosy-lilac tint, with a lighter colour on the reverse side; the lip was tinted rose and purple of various shades, and the whole was furnished with a bright yellow reticulation (First-class Certificate). The variety "rosea" had a lip somewhat darker in tint, and the other segments were of a warm rose-pink flush (First class Certificate); and the variety "aurea" had yellowish sepals and petals delicately flushed with salmon-pink (Award of Merit). With the Phaius were arranged nice examples of *Odontoglossum crispum*, *O. luteo-purpureum*, *O. Wilckeanum*, *O. cirrhosum*, *Oncidium spillopterum*, *Lælia rubescens*, *Lycaste gigantea*, *Masdevallia* × *falcata*, &c. A Bronze Banksian Medal was awarded.

T. B. HAYWOOD, Esq., Woodhatch, Reigate (gr., Mr. C. J. Salter), showed a group of *Dendrobium* × *Ainsworthi*, "Woodhatch var.," which is a fine variety with creamy-white large blossoms, having the base of the lip of a purple tint (Award of Merit); also plants of *Lælio Cattleya* × *Haywoodi*, of the L. C. × Hippolyta section, with flowers of dark orange tinged with rose.

C. L. N. INGRAM, Esq., Elstead House, Godalming (gr., Mr. T. W. Bond), showed a group consisting of thirty-six finely-cultivated plants of *Dendrobium* × *splendissimum grandiflorum*, for which a well-merited Cultural Commendation was awarded.

ELIJAH ASHWORTH, Esq., Harefield Hall, Wilmslow, Cheshire (gr., Mr. Holbrook), showed *Cattleya Trianaei* *Ashworthiana*, a very finely-shaped flower of a delicate peach-blossum tint, with a darker rose hue on the front of the lip, reminding one of C. Schroderæ.

MESSRS. HUGH LOW & Co., Clapton, showed *Odontoglossum nebulosum pardinum splendens*, one of the largest and most handsomely-spotted forms of *O. nebulosum* yet seen (Award of Merit); also *Cattleya Trianaei* *Venus*, a fine white flower, with yellow centre and rose-pink front to the lip.

MR. OTTO FRÖBEL, Zurich, sent *Spiranthes colorata maculata*, referred to in the *Gardeners' Chronicle*, Feb. 19, p. 112 (Botanical Certificate).

MR. E. ZOLLINGER-JENNY, Wollishofen, near Zurich, sent a fine branched spike of *Odontoglossum ramosissimum superbum*, with flowers of a clear white, handsomely spotted with purple (Vote of Thanks).

E. I. MEASURES, Esq., Camberwell (gr., Mr. H. J. Chapman), showed a fine plant of the singular *Pleurothallis punctulata*, with black and silvery-white flowers of curious structure.

W. S. ELLIS, Esq., Hazelbourne, Dorking (gr., Mr. W. S. Barrell), showed *Dendrobium* × *Cybele*, Ellis's variety, with flowers larger than the original.

H. SHAW, Esq., J.P., Birch Vale (gr., Mr. J. Cliffe), showed *Odontoglossum crispum*, *Heathfield* var., and *O. Schillerianum*.

J. T. BENNETT-POE, Esq., Holmewood, Cheshunt (gr., Mr. Downs), showed *Epidendrum Stamfordianum*.

WALTER C. WALKER, Esq., Winchmore Hill (gr., Mr. George Cragg), sent *Acineta Humboldtii*.

MESSRS. FISHER, SON & SIBBAY, Handsworth, Sheffield, showed a fine form of *Dendrobium Wardianum* album.

J. RUTHERFORD, Bearwood, Blackburn (gr., Mr. J. Lupton), showed *Odontoglossum Andersonianum* *Rutherfordianum*, a very distinct form of the *Ruckerianum* class; also a very fine, nearly unspotted variety of *O. Andersonianum*, and *O. Wilckeanum*.

E. HOCKLIFFE, Esq., Uppingham, sent *Odontoglossum Andersonianum*.

The Right Hon. Lord LEIGH (gr., Mr. H. T. Martin) sent fine flowers from his plant of *Lycaste Skinneri*, which had previously flowered with twenty-five blooms.

MR. WM. MURRAY, The Gardens, Oakwood, Wylam-on-Tyne, showed his patent Orchid-stands, illustrated in the present issue for elevating the plants above the staging [fig. 63]. They are designed to prevent fungoid growth arising from stagnant air, which sometimes collects in inverted pots, and is detrimental to Orchids.

Fruit Committee.

Present: T. F. Rivers, Esq., in the chair; and Messrs. Geo. Bunyard, A. F. Barron, W. Poupart, G. W. Cummins, Jas. H. Veitch, T. J. Saltmarsh, A. H. Pearson, J. Wright, Alex. Dean, J. W. Bates, Jno. A. Laing, C. Herrin, Geo. Wythes, H. Balderson, F. Q. Lane, Jas. Smith, G. Reynolds, Robt. Fife, and J. Willard.

The competition amongst exhibitors of Apples and Pears has dwindled considerably, owing to the few available varieties of either. In Apples, C. P. SEROCOLD, Esq., Taplow Hill (gr., Mr. Bullock), was 1st, with Cox's Orange Pippin; and T. B. HAYWOOD, Esq., Woodhatch Lodge, Reigate (gr., Mr. C. J. Salter), was 2nd, with *Bess Pool*, the produce of

bushes worked on the Paradise, and growing on sandy soil. Other varieties shown were Sturmer Pippin, D'Arcy Spice, Reine des Tardives, Fearn's Pippin, Reinette du Canada, and St. John's Seedling.

A dish of Pear Bergamotte d'Esperen received a 2nd prize. The fruit was taken from a pyramid growing on clayey loam overlying clay; it was shown by Mr. R. MAHER, gr., Yattenden Court, Newbury.

We are now doubtless at the end of these competitions for the season; and while, on the whole, these have doubtless been of interest to amateurs, they have not furnished anything that was not previously of common knowledge, and we do not remember that they have caused any good new variety, or one which, from the lateness of its flowering, would be likely to escape injury from May frosts, to be brought forward.

MR. C. P. SEROCOLD's gardener showed ten dishes of well-kept Apples, of dessert varieties, viz., St. John's Seedling Court of Wick, Claygate, and Hubbard's Pearmain, Baddow's, Blenheim Orange, and Cox's Orange Pippins, and Egremont Russet. An Award of a Bronze Banksian Medal was made.

Mrs. WINGFIELD, Amptill House, Herts (gr., Mr. W. J. Empson), obtained a Silver Banksian Medal for twenty dishes of Apples and a dish of Uvedale's St. Germain Pear. The fruits were in most instances clear in the skin, and bore evidence of having been well preserved.

The nice-looking Cucumber, Every Day, which has been previously shown by Mr. THOMAS, the Queen's gardener, Frogmore, obtained on this occasion a First class Certificate. The fruits were about 1½ foot long, smooth, spineless, with a short handle, and of a deep green colour; and, what is more important, fully developed.

Some bundles of excellent Asparagus, cut from permanent beds, forced by means of fermenting leaves and dung in the

FIG. 63.—MURRAY'S PATENT ORCHID-STAND

intervening alleys, very appetising-looking, and of a pinkish-white colour, gained for Mr. G. Wythes, gr. to Earl Percy, Sion House, a Cultural Certificate. Mr. Wythes likewise showed three varieties of the Jerusalem Artichoke, viz., Vilmorin's, a dirty white skinned tuber, resembling somewhat the old Fir-cone Potato in form and the number of its eyes; Long White, which has the appearance of thickened rhizomes rather than tubers. Many of these were 8 inches in length, and 1½ inch in diameter, and with but few buds; the third was Sutton's White, a long, oval form, of even outline. He also showed fruits of Telegraph Cucumber.

MESSRS. H. LANE & SONS, Great Berkhamsted, showed basketful of Prince Albert Apple, excellently kept, being plump, and high of colour; and a few of Rosemary Russet.

Good examples of Variegated Kales came from Messrs. J. VEITCH & SONS, Ltd.

NOTTS HORTICULTURAL AND BOTANICAL.

MARCH 1.—The annual meeting was held on the 1st inst. in the Exchange, Nottingham. Councillor C. SMITH (Chairman of Committee) presided. The sixteenth annual report referred to visits made by members of the society and friends on July 1 to the gardens of Rufford Abbey, the residence of Lord Saville, and to Sandringham, the residence of H.R.H. the Prince of Wales, on July 28. Both visits were greatly appreciated.

The summer show was held on July 14 and 15, in the grounds of the Arboretum, and was the finest the society had held for a number of years. A fruit meeting was held on Oct. 28, when over 300 dishes were staged. A Chrysanthemum

meeting was held on Wednesday, November 7, in the Mechanics' Lecture Hall. The numerous and representative exhibits sent in by the members raised the meeting to the rank of an exhibition. The receipts were:—Annual dinner, £6 9s.; balance from smoking concert, £1 5s. 9d.; excursions, £276 1s. 6d.; annual flower show, including special prizes, £165 1s. 5d.; members' subscriptions, £112 6s. 6d. There were losses of £1 3s. 10½d. on the dinner, and of £64 16s. 4d. on the annual show, while there was a profit of £38 18s. on the excursions. The year closed with a balance in hand of 13s. 8d., a balance in the bank on general account of £25 17s. 1d., and a reserve of £20 in the bank on excursion account.

The Duke of Portland was re-elected president, and the hon. treasurer and auditor were also re-elected. Mr. C. J. Mee was subsequently elected hon. secretary in succession to Mr. Stewart, who resigned after eight years excellent service.

THE SCOTTISH HORTICULTURAL ASSOCIATION.

MARCH 1.—A crowded meeting of the Association was held in Donall's Rooms, George Street, on the above date. MATTHEW LORD, Esq., the president of the association in the chair. The minutes of the last meeting were read by the secretary, and several new members proposed. The president then called upon Mr. IRELAND of Broughty Ferry, to read his paper on Orchids, introducing him as a very successful cultivator of these plants. The lecturer exhibited some fifty illustrations of beautiful Orchids, mostly of his own growing, as well as photographs. These showed, as well as his running commentary on the choicest species and varieties, and many useful cultural hints, his thorough acquaintance with his subject, and gave great pleasure to the audience. The more popular and striking species were touched upon, and the lecturer's historical and cultural notes were specially valuable.

Next came the crossing of Orchids for obtaining varieties or hybrids, and reference was made to the skill and patience required by those who engage in this kind of work.

On the motion of Mr. M. DUNN, a hearty vote of thanks was passed to Mr. IRELAND; and the president announced that the next meeting would be a social gathering to celebrate the coming of age of the Scottish Horticultural Association.

ISLE OF WIGHT.

MARCH 5.—The monthly meeting of the Isle of Wight Horticultural Improvement Association was held at Newport on the above date, Dr. J. Groves, B.A., J.P., in the chair. A large number of members were present to hear a paper read on the "Cultivation of Asparagus," by Mr. J. H. PERKIN, The Gardens, Los Altos, Sandown, who was himself unable to be present, and the paper was read by the Chairman.

A collection of Cyclamen was staged by Mr. B. PARSONS. It was decided to develop the April meeting into a show of spring flowers, and that it should be held at Shanklin. S. H.

CHESTER PAXTON.

MARCH 5.—At a meeting of this society held in the Grosvenor Museum on the above date, the Hon. Sec., Mr. G. P. MILN, gave an address on "The Life and Work of the late Sir Joseph Paxton, M.P." At the outset, Mr. Miln made mention of the fact that there had never been any biography published of this "Prince of Gardeners," and it was not without some difficulty that a complete life history of him had been obtained. [See *Gardeners' Chronicle*, June 17, 1865.] The lecturer described Sir Joseph as one of the great men of this century, and traced his career from the time he became an apprentice-gardener to the period when he was returned Member of Parliament for Coventry. His great work at Chatsworth, his valuable contributions to botanical and horticultural literature, are well known to gardeners generally; but the crowning effort of his life was undoubtedly the designing of the building in Hyde Park, in which was held the great Industrial Exhibition of 1851, and which was afterwards reconstructed at Sydenham. For this he received the honour of knighthood, a well-earned distinction. The later years of his life were devoted to commercial enterprises of various kinds, the development of railways, &c.; but he never lost that love of gardening which he had so studiously cultivated in early life.

On the initiative of the president (Mr. N. F. Barnes), Mr. Miln was heartily thanked for the trouble he had taken in getting together so many interesting facts concerning the life of Paxton, and a hope was expressed that these would be published in pamphlet form.

READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

MARCH 7.—One of the largest attendances of member during the present season assembled on the above date in the club room under the presidency of Mr. C. B. STEVENS, to hear a paper on "The Cultivation of a few useful Flowering Plants for Stove and Warm Greenhouse," by Mr. Townsend, gardener to Sir Wm. FARRAR, Sandhurst. The following subjects were touched upon, and short but ample cultural

instructions were given of each variety: *Achimenes*, *Begonia manicata*, *B. Ingrami*, *B. fuchsoides*, *B. insignis*, *B. coralina*, *Justicia speciosa*, *J. flavicoma*, *Heterocentrum roseum*, *Centradenia rosea*, *Centropogon Lucyanus*, *Clerodendron splendens*, *C. Balfouri*, *Scutellaria mocciniana*, *S. pulchra*, *Eranthemum pulchellum*, *Thysanthus rutilans*, *Dendrobium nobile*, *Anthurium Scherzerianum*, *Phajus grandifolius*, *Zygopetalum Mackayii*, *Libonia floribunda*, *Habrothamnus Newelli*, *Streptosolen Jamesonii*, *Salvia Pitcherii*, *Diplacus hybridus splendens*, *Torenia Fournierii*, *Esacum affinis*.

A lengthy discussion took place, which drifted chiefly to the advantage or disadvantage of pruning *Dendrobium nobile*. An interesting collection of cut blooms was exhibited by the lecturer, the most noticeable being *Centradenia rosea*, *Clerodendron Balfouri*, *Phajus grandifolius*, *Zygopetalum Mackayii*, *Habrothamnus Newelli*, *Streptosolen Jamesonii*, and the various *Begonias* named above.

CATALOGUES RECEIVED.

R. H. BATH, LTD., The Floral Farms, Wisbech—Carnations, Pansies, Violas, Begonias, Cannas, Dahlias, &c.

F. H. HORSFORD, Charlotte, Vermont, U.S.A.—Hardy Miscellaneous Plants.

KENT & BRYDON, Darlington—Agricultural Seeds.

RIVOIRE & FILS, 16, Rue d'Algerie, Lyons, France—Trade List of New Plants.

FRED. W. KELSEY, 150, Broadway, New York—Trees and Shrubs, Hardy Vines, Roses, Fruit-trees, &c.

W. P. LAIRD & SINCLAIR, Dundee and Cupar, Fife—Farm Seeds.

TOOGOOD & SONS, Southampton—Farm Seeds.

COOPER, TABER & CO., LTD., 90 and 92, Southwark Street, London, S.E., Wholesale List of Farm Seeds.

HOGG & ROBERTSON, 22, Mary Street, Dublin, Agricultural Seeds.

HARRISON & SONS, Leicester—Agricultural Seeds.

LOUIS VIEWEG, Quedlingburg, Germany—Seeds, Orchids, Succulents, Clematis, Passifloras, Hardy Plants, &c.

PINEHURST NURSERIES, North Carolina, U.S.A.—Trees, Shrubs, and Herbaceous Plants.

V. N. GAUNTLET, Green Lane Nursery, Redruth—Hardy Bamboos, Hardy Palms, Japanese Maples, Himalayan Rhododendrons, &c.

HERD BROS., 47, King Street, Penrith—Agricultural Seeds.

PETER LAMBERT, Treves, Germany—New Roses of own raising, White Maman Cochet, Red Maréchal Niel, and others.

THOS. S. WARE, Hale Farm Nurseries, Tottenham—(1) Hardy Perennials; (2) Hardy Florists' Flowers.

JAMES BACKHOUSE & SONS, York—Alpine Plants, Hardy Perennials, and Florists' Flowers.

GARDENING APPOINTMENTS.

MR. T. COLLINGS, for four years foreman in The Gardens, Swallowfield Park, as gardener to Mr. Fairfax Wade, Holme Park, Twyford, Berkshire.

MR. ROBERT MINARD, for the past six years Head Gardener to T. R. SYMONS, Esq., of Mynde Park, Herefordshire, as Head Gardener to JAS. RANKIN, Esq., M.R., at Bryn-gwyn, Herefordshire.

BOOKS: A. R. *The Nursery Book*, by L. H. Bailey, published by the Rural Publishing Co., New York; see also *Gardeners' Chronicle* for 1897 for a series of exhaustive articles on the subject of plant-propagation.—E. K. *The Orchid Manual*, by B. S. Williams, sold by the author at the Victoria and Paradise Nurseries, Upper Holloway.

FRAMES FOR MAKING TOPIARY WORK: T. G. We are not aware that there are professional makers of frames for this kind of garden "adornment," but any worker in wire would be able to fabricate what you desire. If this note should meet the eye of our Dutch friends who indulge in these things, they may kindly proffer the desired information.

GARDENIAS: *Grower*. The quotation 6s. was actually paid by a dealer in the Central Avenue last week.

GRUB ON APPLE LEAVES: B. J. Hughes. Hand-picking when the grubs show. You do not say what sort of grubs. Please send a sample when properly developed, and we can then answer your question fully. Petroleum emulsion, tobacco water, soft soapy water, Quassia water, are all good in making the leaves distasteful to the feeding grubs.

LOAM: G. S. K. The loam is of a heavy clayey nature, but on being rendered porous it would not be unsuited to the growth of fruit trees of all kinds, Melons, Pines, for soiling Mush-

room beds, for Roses in pots or beds, Conifers, &c. To render it porous employ for potted plants either sand or leaf mould; and out of doors, charred earth, sand, ashes, road grit, &c. There were no insects found in it.

LYCASTE: *Veritas*. The species named usually flowers in summer and autumn. It should be grown in the intermediate-house.

MARKET GARDENING IN CORNWALL: B. For early crops, say of Strawberries, Gooseberries, and small fruits generally, Broccoli, Cauliflower, Potatoes, &c., the south-eastern parts of the county should be selected, these being warm and less swept by the Atlantic gales than the western and north-western parts. The districts served by the Great Western Railway, and therefore in connection with the great midland and northern towns, would be the best. Rent of good land is not low, and we should suppose that land let for gardening purposes would be more highly rented than farm land. We are unable to answer your inquiries regarding the chances of a short term of employment on an established place. Why not advertise your wants in these pages. Bulb (*Narcissus*) growing is the staple industry of the Scilly islanders, and brings in better returns than the cultivation of the Potato, once their sole industry but now almost relinquished.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—J. R. *Coelogyne graminifolia*.—J. B. Your newly-imported *Dendrobium nobile* is a very fine variety. Its odour as well as its colour is different from the old type of *D. nobile*.—J. J. *Hebeclinium atrovirens*; 2, *Cupressus funebris*; 3, *Bilbergia nutans*; 4, *Cyperus laxus*; 5, *Ophiopogon Jaburan variegata*; 6, *Begonia corallina*.—J. W. 1, *Berberis Bealei*; 2, *Berberis Darwinii*; 3, *Pernettya mucronata*, or var.; 4, *Gaultheria Shallon*; 5, *Hippeastrum (Amaryllis) Johnsoni* var.; 6, *Fuchsia microphylla*.—A. M. D. 1, *Oncidium pubes*; 2, *Oncidium pulvinatum*. The Tomato is affected by disease which commonly affects it when much forced.—J. B., *Chippendale*. 1 and 3, are varieties of *Odontoglossum Andersonianum* of that class commonly called O. *Ruckerianum*; 2, *Odontoglossum Hallii*. All are remarkably fine, and 1 and 3 very distinct.—G. Sleep. *Acacia dealbata*. The propagation is by means of seeds and cuttings of half-ripe wood. The latter put in under a bell glass in sandy peat covered with clean sand and kept in a greenhouse, shading the pot when the sun shines. Indigenous to Tasmania.—T. F. Next week.—H. P. Next week.—H. T. C. 1, *Clivia miniata*; 2, arrived too withered for naming; 3, *Cocos Weddelliana*; 4, a variety of *Selaginella martensii*; 5, *Aglaonema simplex*; 6, *Cordyline australis*, var. *N. E. B.*

NARCISSUS HYBRIDISATION: *Quiz*. See Cassell's *Popular Gardening*, Burbidge's *Cultivated Plants*, *Encyclopædia of Horticulture*, by Nicholson, under "Hybridisation;" and *Gardeners' Chronicle*, March 12, 1892, p. 331.

RHODODENDRONS: W. H. B. Grafting may be done in late summer by employing ripe wood of the current season, and stocks of *R. ponticum* for hardy varieties, or seedlings of Sikkim or Java species that may be obtained from seed for the tender species. These should have been one year in pots at the least, and be as large as a goosequill at the ground level, and should be headed down, a leaf or two being left at the top; below which point the graft is put on by any of the various methods. Sometimes cleft grafting is employed, the graft being then inserted at the apex of the cut down stem; leaves on opposite sides of the stem being retained in this case likewise. The grafts should be tied in, and afterwards coated with grafting-wax, and the plants put into cool glass case or frame within a glasshouse. The same kind of stocks may be used for inarching Rhododendrons, say in June, both in the case of hardy species out-of-doors or others under glass; it is a safe and easy method where only a few plants are required. In the case of the warm-house varieties, a temperature intermediate between that of the stove and the greenhouse is best for the grafts. As it is not desirable in the case of grafts to encourage growth after August, at which time the grafts will be taken, the stocks should be removed to more airy quarters—not all of them at one time, but such as show on close examination that an union has taken place—and gradually inured to the outer air in the case of hardy species, or to the air of the intermediate house in

the case of the others. The hardy ones should be wintered in glass frames, or under some rough sort of protection, as bamboo shading, pea or bean sticks, and the pots protected from being broken by frost by sinking them in the soil or in coal-ashes. We are unable to inform you if the writer of the articles on "Plant Propagation" intends to publish them in book form.

ROSE LEAF: R. S. A chill from overhead syringing. No fungus present.

SNOWBERRY BUSH (*SYMPHORICARPUS RACEMOSUS*) AND FARM STOCK: K. S. J. W. The berries are not poisonous. Wild animals are discriminating, and avoid them, but tame ones seem to have their instincts blunted by misuse.

SOME METHODS OF PROPAGATING ROSES: *Elsie*. The method of striking the cuttings in bottles of water is not a very certain one, or one that will result if successful in obtaining healthy plants. If only a few plants are wanted, and the mother plants are in flowerpots, sink these in the soil after putting a handful of soot or coal ashes at the bottom of the hole as a deterrent to worms, that might otherwise get into the pots, and layer the upper 8 inches of each stout shoot of last season's growth, two inches deep in the ordinary soil, or into a potful of soil also sunk in the ground, fastening each shoot with a wooden hook. If done in April the layers will be rooted in July, and in early September they may be detached from the parents, and planted elsewhere or potted. It is better than taking cuttings where but few plants are looked for, and is but little trouble. Cuttings of ripe wood may still be put in, in the open border, but the best time is October. The cuttings should be made from ripe, stout shoots, one foot in length, taken off with a "heel," a slice of the previous year's wood, and put into the soil to two-thirds of their length, and made firm by pressure. Cuttings of half-ripened shoots also furnished with a "heel" and with leaves too, which however must be slightly reduced in size, strike well in 3-inch pots filled with sandy soil, placed on, or plunged in a mild hotbed in early July. They must be kept moderately moist, and the frame very close always, and shaded from bright sunshine. In three weeks or a month if damping off has not occurred, the greater number will be rooted. If damping appears likely to occur, air must be given for a quarter of an hour about 10 A.M. on alternate days.

STOPPING CERTAIN VARS. OF CHRYSANTHEMUMS: *Grower, Cheshire*. We think that you mean "taking the bud." You should obtain a manual on cultivating the plant, or take your inquiry to some one who makes a specialty of Chrysanthemums.

TENANCY OF LAND: B. E. C. Six months' notice on either side, the tenancy terminating on the day upon which it was entered.

WARTY EXCRESCENCE ON VINE STEM: C. Price. The excrescences on the Vine stem do not constitute a disease, being simply the abnormal development of latent buds. Such buds in Vines are most abundant in the axils of weak leaves and leaf-scales formed near the base of the stem when the plant is quite young, and may remain latent for a long period of years, eventually forming rugged excrescences, sometimes of a very large size. G. M.

WOODLICE: *Anxious*. We fear you never read your *Gardeners' Chronicle*. Consult the issue for February 12 last for antidotes against these creatures.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,

MORE THAN DOUBLED,

and that it continues to increase weekly.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

(For Markets and Weather, see p. xv.)

THE Gardeners' Chronicle.

SATURDAY, MARCH 19, 1898.

A BOTANIST WITH THE ECLIPSE EXPEDITION.

TO witness the total eclipse of the sun on January 22, 1898, a few observers journeyed from America and Japan, and many from nearer centres, to the neighbourhood of the village Jeur, in the Deccan, India, because it stands near the centre of the twenty-five miles wide line of totality, and two minutes four seconds would be available to record on photographic plates the spectroscopic lines which tell of certain elements in the vapours that constitute the corona, visible only during a total eclipse. The astronomers were furnished with the best appliances known, details of which need not here be given.

On the day in question, about noon, the moon began to steal gradually over the face of the sun, light began to fade, Leguminosæ to fold up their leaves as their manner is at fall of evening, and when the black shadow of the moon came out of the west like a swift moving cloud, the darkness became that of a clear night; the breeze fell, a few stars were visible, all nature hushed, and one felt that "All the air a solemn stillness holds." The manipulation of apparatus to the measured beat of a pendulum left time for only a hasty glance at the brilliant corona; with that, and the results, astronomers must be left to deal.

The soil of the district is disintegrated trap-rock, in some places only a few inches deep, in other places several feet in depth, of a fine black loam, excessively encumbered with large roundish stones, neither water-worn nor scratched, evidently hard nodules of the rock from which the soil is formed. Rain in this district is confined to the months including June and September, and averages 25 inches yearly. The daily range of temperature during January in the open, was from 45° F. to 145° F., and in the shade from 50° F. to 90° F. Under such conditions luxurious vegetation could not be expected. In the fields Sorghum was the principal crop, and the people were awaiting its ripening with anxious eyes. Linseed growing a foot high, as its manner is in India, was frequent, and Carthamus tinctorius, the source of Safflower and a useful oil, showed its yellow flowers and prickly foliage in every field. Irrigated Wheat, Melons, Onions, and several kinds of Beans were to be seen near wells.

Of the natural vegetation the most prominent features were thorny Acacias, Prosopis spicigera, Dichrostachys cinerea, Cassia auriculata, Croton retusa, and Cardiospermum Halicacabum. The district had no crops in the season 1896—1897, but the people had been relieved to some extent by Government works, and food supplies brought from other countries by the Famine Relief Organisation. At the time of our visit fodder was abundant, but grain was scarce and dear, and many people were subsisting by the aid of the seed of Cyanotis axillaris, and of Indigofera linifolia, I. cordifolia,

I. glandulosa, and Panicum Isachne, which grow wild in profusion, and appear to thrive well when rainfall is scanty.

In all, 130 species of plants were collected, including 26 Gramineæ, 27 Leguminosæ, 14 Compositæ, 9 Acanthaceæ, 5 Asclepiadaceæ, 5 Euphorbiaceæ, 5 Malvaceæ, 5 Cucurbitaceæ, 5 Convolvulaceæ, 2 Solanaceæ, 4 Labiatæ, 2 Urticaceæ, 2 Capparidaceæ, the remainder being represented by one or two species in a Natural Order.

Of the Gramineæ, the most frequent one, Aristida setacea, was in ripe seed, and the manner in which this species distributes its seeds is very interesting; its three-branched awns twist together in such a manner that a perfect sphere is formed by their extended points, and the balls roll hither and thither in every breeze. One would appear at the door of the tent like a shy stranger, uncertain whether to advance or retreat; a puff would drive it in a foot, another would send it out again, a third would make it roll straight to one's feet. Another grass of interest is a species of Isachne, undescribed and remarkable for its habit of setting loose its entire

Sent by an old correspondent.

FIG. 64.—ECLIPSE OF THE SUN ON JANUARY 22, 1898, AS SEEN AT JEUR, IN THE DECCAN.

inflorescence, a large open panicle of most elegant form, which is rolled about by the wind till it is caught in some bush. As this species has an inflorescence larger than any other known, and was found while preparing to observe the eclipse, the name Isachne obscurans is proposed for it in the attached description.* G. Marshall Woodrow, Professor of Botany, College of Science, Poona, India.

NEW OR NOTEWORTHY PLANTS.

CATTLEYA TRIANÆI VAR. ALBIDA.

A BEAUTIFUL white form of Cattleya labiata Trianæi named as above, has flowered with Captain G. W. Law-Schofield, New-Hall-Hey, who has kindly sent a flower. The sepals and petals are white, the latter

* Isachne obscurans, Woodrow, sp. nov.

Stem short, ascending, annual.

Leaves 3½ to 5 inches by ½ inch at widest, lanceolate hispid, margins thickened, ciliate. Sheath shorter than the leaf, hispid.

Panicle attaining 15 by 12 inches, pyramidal, lax, ultimate branchlets pendulous, few flowered; peduncle equal to height of panicle.

Spikelets ½ inch. G.I. ¾", 7-hispid-nerved; G.II. ¾", 7-nerved, broader than I., and with a black gland at base; G.III., 7-nerved, slightly shorter and broader, but otherwise as I. and II. Pale, half as long as glume, 2-dentate; G.IV., and pale ¾", 5-nerved, smooth, crustaceous.

The whole inflorescence breaks off and is driven about by the wind. Vernacular name, Tan Sawa, grain used for fast-day food; cooked like rice. G. M. W. [In the opinion of Dr. Stapf this is a true Panicum. Ed.]

broad and finely crimped at the margin. The lip is also white, with chrome-yellow lines radiating from the base, and the front lobe is of the delicate bluish-pink hue seen in the flowers of some varieties of Heliotrope. White varieties of C. Trianæi are rare, and always beautiful, and its appearance in an amateur's collection is looked upon as a very desirable event. James O'Brien.

CIRSIIUM CANDIDISSIMUM, Dammer.*

This new annual Cirsium was found by Mr. Siehe of Mersina, in the mountains of Cappadocia. It attains a height of 3½ metres. The large, sessile, decurrent leaves are about 16 ins. long, 8 to 10 ins. broad, sharply toothed, undulated, and as the whole plant bright silvery-white. The branched inflorescence bears rose-coloured heads of about 1 inch in diameter. It is a very ornamental plant, to be grown as a specimen in loamy soil. U. D.

ORCHID NOTES AND GLEANINGS.

DENDROBIUM NOBILE.

ONE of the finest examples of this plant I have ever seen was noticed recently in the gardens of Mrs. Knowles, Moor Head, Shipley, Yorkshire (gr., Mr. Moorby). The above specimen was in an ordinary teak basket, measuring 16 inches square, and it bore nearly 1000 blooms, on seventy-five growths. There were five such specimens carrying altogether upwards of 3000 blooms, which is a great testimony to the skill and care taken by Mr. Moorby, the gardener.

SACCOLABIUM BELLINUM.

This handsome and richly-coloured species, which was discovered by Mr. Boxall in Burmah in 1873, and sent to Messrs. Low, ranks highest in point of floral beauty over any of the four or five species of its section, whose smallest, but still pretty, representative is S. calceolare. A very beautiful example of it is sent by Mr. William Gould, of Rose Bank, Hayfield, near Stockport. The sepals and petals are bright yellow, so densely spotted with purplish-brown that only a slight reticulation of the yellow appears. The pouch base of the lip is white, spotted with bright purple and yellow at the base, the downy, two-lobed front being white, with a yellow blotch bearing some purple spots in the centre. It is a very quaint and attractive species. J. O'B.

VANDA ROXBURGHII.

Mr. P. Lancaster gives, in the last number of *Indian Gardening*, a detailed comparative account of the variations, thirty-nine in all, that he has met with in this species.

FLOWERING OF PHALÆNOPSIS SCHILLERIANA.

M. J. C. de Lange, of Rotterdam, has a plant of Phalænopsis Schilleriana imported last year, and now bearing a large branching raceme covered with fine flowers. Five or six other specimens have some concluded, others commenced blooming here, where they are considered a specialty.

DIURIS MACULATA.

This small genus of terrestrial Orchids is an interesting one by reason of its peculiar flowers. The flower-spikes generally grow here to about 9 inches high—but in their native habitat of Australia, they are said to grow as high as two feet. Each spike bears several flowers near to the apex; these are yellow, spotted with brownish-purple spots. The erect lateral sepals are spreading and wing-like, and give to the flower an insect-like appearance. The leaves are long and narrow, and die away during the summer, but fresh ones appear above ground in March. We grow them upon a shelf near the glass at the cool

* *Cirsium candidissimum*, Dammer, nov. spec.—Annuum, caule simpliciter ad 3–5 m. alto; foliis sessilibus lanceolatis acutis undulatis runcinato-serratis, decurrentibus ad 40 cm. long., 20–25 cm. lat.; inflorescentia racemosa; capitulis 2½–3 cm. diam.; floribus roseis. Tota planta nitide argentea. Crescit in montibus Cappadociae Asiae Minoris ubi legit cl. W. Siehe. U. Dammer.

end of the intermediate Orchid-house. This species flowered at Kew in 1825, and is figured in the *Bot. Mag.*, t. 3156. *R. L. H., Edinburgh.*

ORCHID PORTRAITS.

The following are the Orchids figured in the last issued part of M. Cogniaux's useful *Dictionnaire Iconographique des Orchidées*:—

THE CINCHONA IN INDIA.*

My remarks this evening on the Cinchona industry in India will be chiefly confined to my own experience in British Sikkim, where I held executive charge of the Bengal Government plantations from the year 1865, when they consisted of a quarter of an acre only, till seven months ago, when I retired from active service. For the last twenty years of my service I also had charge of the factory which was started at the plantations for the extraction of the Cinchona products. So I shall have something to say on the manufacture as well as the culture of the Cinchona.

Quinine is principally got from the bark of trees and shrubs belonging to the genus *Cinchona*. Indeed, till about twenty-seven years ago it was hardly known that it was obtainable from any other genus; but it was then ascertained that the bark of an allied genus, *Remijia*, also yielded it, although in smaller proportion. In 1880, and for several subsequent years, when Cinchona bark was scarce and dear, and quinine selling at famine prices, *Remijia*, or *Cuprea* bark, as it was commercially called, was imported from S. America for the European quinine factories in very large quantities; but later on, when the markets became stocked to overflowing with the rich cultivated Cinchona barks of India, Ceylon, Java, S. America, and other countries, prices fell, and the importation of *Cuprea* bark became unprofitable, and, consequently, ceased. The price of quinine is now so low that it would hardly pay the manufacturers to work up *Cuprea* bark, with its small proportion of alkaloids, even if they got it for nothing; for the expensive manipulation of a large quantity of bark, to get only a little low-priced quinine cannot be a profitable operation. Owing to over-production, the price of both Cinchona bark and sulphate of quinine has fallen so low, that the planters get actually less for the bark than it costs them to grow and market it, whilst the quinine makers can hardly have fared much better; but the fever-stricken millions of the malarious parts of India and other hot countries reap the benefit; and to benefit them, rather than either planter or manufacturer, was the avowed object of our Government in introducing the Cinchonas to India and other countries. The results have exceeded the most sanguine expectations, for the introduction has been the means of bringing the price of quinine so low as to place it within easy reach of the very poorest. It is one of the few medicines of foreign manufacture that the natives of the East, almost without exception, implicitly believe in, and their confidence in it is likely to continue whilst quinine remains so cheap that there is but little temptation to adulterate it. Many substitutes have been from time to time put on the market, but not one has stood the trial test, and quinine is likely to remain, as it so long has been, the only safe specific for malarial fevers.

FORMATION OF PLANTATIONS.

First, then, concerning the formation of plantations. The planter in the East has no convenient nurseryman to indent on for his plants as his brother at home has, so must raise his own, and, in fact, do everything for himself, from the making of bricks to the building of factories and fixing machinery. In Sikkim there were, practically, but two methods of raising plants practised, viz., by seed and by cuttings. In the earlier years of the enterprise seed was not obtainable, and plants had to be raised from cuttings, which was done in the ordinary way. There were three main species to deal with:—*Succirubra*, or Red-bark; *Officinalis*, or Crown-bark; and *Calisaya* var. *Ledgeriana*, or Yellow-bark. Usually 95 to 100 per cent. of the *Succirubra* cuttings

rooted without any trouble, but *Officinalis* was not so accommodating, although not very troublesome, and *Ledgeriana* was almost a complete failure, for of many and many a batch of it not a single cutting rooted, and seldom more than 5 to 10 per cent.

There was nothing peculiar either in the way the seedlings were raised. The seed was sown in long, narrow, terraced beds, protected by low thatched roofs from rain and sun, but open at the sides for free admission of air and light. The seedlings were kept in the same sort of protected beds, with several transplantings, as they grew and required more room, till 6 or 9 inches high, when advantage was taken of a spell of dull weather to remove the thatch and get them inured to the weather previous to planting out in the plantation. The sites selected for plantations were on the steep mountain slopes, at elevations lying between 1,000 and 5,000 feet, flattish ground being avoided, as Cinchonas cannot long endure stagnant water at their roots; and artificial drainage, however elaborate, does not do much good with a yearly rainfall of 120 to 250 inches. On the selected sites the jungle, usually consisting of a mixture of trees, bamboos, and shrubs, is cut close to the ground, and great care taken to leave nothing uncut to ensure everything dying and drying together, otherwise there might be an imperfect burn which would entail extra work in the final clearing. The cutting is best done in December, after the dry season has fairly set in, and the burning in the end of March, when the weather is hot and dry. After the ground is cleared, roads have to be traced and made, and pegs put down in straight rows at the distance apart it is proposed to plant, usually 4' to 6 feet each way. Then pits of about 2 feet across and nearly as much in depth are dug out, and afterwards filled in with the same soil mixed with any convenient decayed vegetable-matter, and on those little mounds the plants are firmly planted, one at each peg, after the soil has been well saturated with rain, and the sky is overcast. At the time of planting, the seedlings are usually from twelve to fifteen months old, counting from date of the sowing. For three or four years the ground between the plants has to be kept fairly free of weeds, and occasionally dug over. Afterwards but little cultivation is necessary, as the plants will be covering the ground and able to take care of themselves.

RED BARK.

When the first plants were large enough to yield bark suitable for chemical analysis, it was found that the Red Bark, whether from seed or cuttings was fairly uniform in quality and of the typical character, i.e., rich in the inferior alkaloids, cinchonidine, and cinchonine, but rather poor in quinine. So it was only a question of expediency whether the plants were raised from seed or cuttings, the result in alkaloids being the same. It is not a good bark for quinine making, but is perhaps the most useful to the ordinary druggist for his tonics and other preparations. The crown bark was also uniform in quality and true to type however raised. It is one of the very best barks for the manufacture of sulphate of quinine, as it is rich in quinine, and comparatively poor in the inferior alkaloids. It thrives to perfection in Travancore and other parts of southern India, but is rather a failure everywhere in the more northern Himalayan regions. Its stem bark will yield from 3 to 6 per cent. of its weight of sulphate of quinine.

YELLOW BARK.

The yellow bark behaved quite differently. The cutting-raised plants, of course, yielded bark of exactly the same composition as the parents, but the seedlings differed in the most perplexing way, both from their parents and from each other. The better sorts yielded from 8 to 10 and even 16 per cent. of sulphate of quinine, but the inferior sorts, which were quite as numerous, or perhaps more so, less than two. To make matters worse, the good sorts are quite indistinguishable from most of the bad till the trees grow up and flower, and not always then even.

LEDGER BARK.

The original seeds, from the Andes, yielded just as mixed a progeny as the Indian grown did in later years. They were collected in Bolivia for Mr. Ledger by his half-caste servant, who was afterwards killed for having procured them for export, and thus destroyed the monopoly of so valuable a product to its native country. These seeds were first offered for sale by Mr. Ledger to the India Office, who refused them, not knowing that they were of any special value, or that they differed from varieties of *Calisaya* already in India. Ultimately they were divided between a Madras private planter, for his plantation on the Nilgiris, and the Dutch Government, for their plantations in Java. Part of the planter's share was afterwards exchanged with the Madras Government for other sorts of Cinchona seed, and, through an old friend, I got a very small packet, from which we raised 800 plants. These were the parents of most of the Ledger plants since grown in India and Ceylon, for the species did not thrive on the Nilgiris, but speedily died out, and the Dutch were careful to reserve the Java-grown seeds of the better varieties for their own use for many years. But till the first-grown bark was analysed, neither the Dutch nor the English had any idea of the value of the prize they possessed, and till the trees flowered the species even was uncertain. The first flowering specimens were submitted to the late John Eliot Howard, the famous London manufacturer of the purest sulphate of quinine ever put on the market. Mr. Howard had made a special study of the genus *Cinchona*, and published extensively on both its botany and chemistry, and was for many years a trusted adviser of Government

on the introduction of the Cinchonas to India, in which he took the keenest interest. So, altogether, he was in the best position to determine the species. He pronounced it to be a variety of *Calisaya*, and named it *Cinchona Calisaya* var. *Ledgeriana*. A few years later Moens, the superintendent of the Java plantations, who was a most excellent analytical chemist, but made no pretence to any knowledge of botany, raised it to specific rank under the name *Ledgeriana*; and Trimen, of Ceylon, agreed with him.

But there can be no doubt, I think, that Howard was right, and that his name ought to stand. At any rate, the Government of Bengal adhere to it. It is a most variable plant in foliage and habit of growth, as well as in coloration of the flowers, which vary from pure white to bright pink. After the general flowering of the trees, chemical analyses showed that those with white, nodding flowers, and small seed-capsules, were rich in quinine, whilst those with pinkish flowers, however slightly tinged, or with straight flower-stalks or large seed-capsules, were poor; but as there is rarely a rule without an exception, it turned out that the very richest of all in Java had pink flowers. But with this notable exception, so far as I know, the rule holds good that the white-flowered varieties are rich in quinine, and the coloured poor. For instance, a mixed sample of bark collected under my own personal supervision from twenty trees bearing white flowers, but differing more or less from each other in foliage and habit of growth, yielded 8 per cent. of crystallised sulphate of quinine; whilst a corresponding sample, collected at the same time and place from twenty trees, with flowers tinged pink, yielded but 2.93 per cent., or nearly two-thirds less; so the formation of plantations, consisting of the rich varieties only, became a matter of the first importance, for it costs no more to grow a rich sort than it did a poor, and the yield of quinine would be more than doubled. But to do this with absolute certainty, some plan of artificial propagation was necessary, as the seedlings often came untrue to type, and sometimes were a very mixed and inferior lot indeed. Attempts at propagation by cuttings had ended in failure everywhere, and layering was a slow and unsatisfactory process. The other obvious plan was grafting, but that in the ordinary way was slow and expensive, as it had to be done under glass-roofs; so in the end, in Sikkim, we had to do the best possible with selected seed, and give up artificial propagation, much to our regret. But in Java, where the climate and soil are both more favourable to Cinchona growth, plants grafted under glass, and afterwards planted out in the open, made good growth, and yielded profitable returns on the expenditure.

GRAFTING.

A good many years ago, a private planter from Java, a Mr. Weinschenk, told me of a discovery he had made in open-air grafting, by which, according to his own account, he got excellent results. In fact, he claimed by it to have almost no failures, and very little expense. But to this I cannot further testify than that I tried his plan on a small scale, and under unfavourable circumstances, but with results that inclined me to view it with favour. His plan was very simple, but new to me. He commenced by making his graft sick, as he phrased it, by ringing its base, and letting it remain on the parent tree till its leaves became of an unhealthy colour, when he cut it off, and fixed it on the stock in the usual way. His whole discovery lay in making his graft sick beforehand, which, to me, appeared a very absurd procedure, but it really may have some reasonable foundation. Perhaps some one will be good enough to give the plan a trial with fruit and other trees at the proper season of the year, and chronicle the results. It should be done when the plants are in active growth. Mr. Weinschenk was a man of many theories, one of them being that the bark of the Cinchona, and not the roots or leaves, had the predominating, if not the entire, influence in the chemical conversion of the sap into the different alkaloids. Once when I was with him on a visit to the Nilgiri Cinchona plantations he asked the late Mr. M. A. Lawson, then Superintendent of the Madras Government plantations, but formerly Professor of Botany at Oxford, and consequently well acquainted with vegetable physiology, where he thought the controlling chemist was located—whether in the leaves, or in the roots, or where? Mr. Lawson answered, off-hand, "In the leaves, of course." "How is it, then," said Mr. Weinschenk, "that if I cut over a *succirubra* plant and graft on it *Ledgeriana*, which I let grow to some height, then behead and graft on a *succirubra* top, when I shall have *succirubra* leaves and *succirubra* roots, but the bark on the Ledger part of the stem, however many years afterwards, and however much it may have increased, will still be normal Ledger bark, and in the same way the *succirubra* bark at top and bottom will continue to be of the typical *succirubra* character, i.e., the Ledger bark will continue to contain a large proportion of quinine and but little of the inferior alkaloids, cinchonidine and cinchonine, and the *succirubra* vice versa. Therefore, said Mr. Weinschenk, I maintain that the controlling chemist is neither in the leaves nor in the roots, but in the bark itself. Of course, the obvious weak link in this chain of argument is the fact that the bark on the Ledger part of the composite tree was started while it bore Ledger leaves. But I think it is suggestive of possibilities of getting branch sports by the engrafting of other bark, and that the bark may really have a large influence in determining the nature of the alkaloids, or the colour of the flowers, or in other ways. It is just possible that some of the inexplicable branch sports may have originated in the accidental engrafting of bark from kindred species or varieties.

(To be continued.)

* Paper read at the monthly *conversazione* at the Horticultural Club on Tuesday, March 8, by Mr. J. A. Gamble.

THE FERNERY.

HARDY FERNS.

(Continued from p. 156.)

To return to division of the Ferns, our remarks so far have only applied to the Crown Ferns, as we may term them, the *Lastreas*, *Polystichums*, and Lady Ferns, but there are other species such as the *Polypodies*, *Bladder Ferns*, and *Asplenias*, which either have

trees in their native habitats. The Spleenworts as rock-loving Ferns, are the better for a little limestone rubble in the soil, but the Hard Fern or *Blechnum spicant* and the Mountain *Lastrea* (*L. Oreopteris*) dislike lime, and prefer leaf-mould and yellow-loam with a dash of sand. The Parsley Fern (*Allosorus crispus*) is rarely seen in collections, but is very pretty out of doors (it will not do under glass) if properly installed. The Fern grows naturally on rocky hill-sides among the loose *débris* or rubble, and we have

slides had occurred among the *débris* of its native hills. Harts-tongues are of such varied character that it is a matter of taste as to their division, but wherever single crowns can be adhered to, the fronds and general developments are certainly enhanced in beauty. A tangle is never pretty, and with this species, as with some of the "crown" species proper, a little perseverance with a robust crown as a start will be well rewarded. *Chas. S. Druery, F.L.S., V.M.H.*

(To be continued.)

A TROPICAL GLASSHOUSE.

EVEN in the tropics glasshouses have their uses in plant cultivation, in that they provide shelter from too ardent sunshine and heavy rain to plants grown in flower-pots. Mr. J. H. Hart, Superintendent of the Botanic Gardens, Trinidad, kindly sent us a photograph of some which he has erected (fig. 65). "The upper roof," he says, "is of corrugated iron galvanised, and the houses stand east and west, so that at mid-day the roof centre affords a large amount of shade. We find that we can now do many things that formerly we could not do at all, as we can protect equally well from wind, sun, and heavy showers. They offer splendid places in which to raise small seeds, &c. The tree to the left top is *Theobroma bicolor*, imported by me from Nicaragua in 1893—its first introduction to the West Indies. It fruited in 1897."

THE ROSARY.

GARDEN ROSES.

THERE are many Roses of the highest importance and distinction which may be described as valuable for exhibition or garden decoration. Conspicuous among these are Madame de Watteville and Anna Olivier, Madame Lambard, and Marie Van Houtte, Madame Hoste, and Catherine Mermet among the Teas; A. K. Williams, Madame Victor Verdier, Margaret Dickson, Duke of Albany, and Alfred Colomb, among the *élite* of the hybrid perpetuals; and La France, Caroline Testout, and Kaiserin Augusta Victoria among the hybrid Teas.

Several of the Bourbons have an equal qualification, among which are the venerable *Souvenir de la Malmaison*, a fine Rose, but easily spoiled by rain; Madame Isaac Pereire and her gifted daughter, Mrs. Paul, Queen of the Bourbons, raised at Cheshunt in 1891.

In addition to the hybrid perpetuals incidentally mentioned, the following varieties may be recommended as being garden Roses, viz.: Duke of Edinburgh, which has a velvety texture that easily distinguishes it from other crimson-coloured Roses; Duke of Wellington, an over-estimated variety; and Duke of Albany, a very beautiful variety, whose most formidable rival in this section is Prince Arthur, raised by Mr. Benjamin R. Cant in 1875. Horace Vernet, though rich and effective in colour, is not trustworthy. A little more dependence can be placed on such very dark crimson varieties as Abel Carrière and Prince Camille de Rohan; though their flowers, I find, are easily tarnished by a strong sunshine. A much more valuable Rose for the garden is Charles Lefebvre, whose introduction, as Dean Hole once said to me at Rochester, "marked a distinct epoch in the history of Rose-cultivation." It is considerably larger and of more perfect form than the Duke of Edinburgh, yet its colour has not for me the same fascination. Captain Hayward, raised by the late Henry Bennett, is a fragrant and highly effective "scarlet-crimson" variety that should be included in every representative collection. Among pink varieties, and those of a lighter shade, the finest are Mrs. Sharman Crawford, Mrs. John Laing, Madame Gabrielle Luizet, Clio, and Spenser, the latter an improvement on Baroness Rothschild. The remarkable merits of A. K. Williams, Duke of Albany, and Margaret Dickson have already been recorded; for garden culture these may be regarded as quite indispensable. Hybrid Tea Roses have now become an important

FIG. 65.—A GLASSHOUSE IN THE BOTANIC GARDEN, TRINIDAD.

running roots with fronds at short intervals, or form bunches on a small scale. Clearly with plants of this class, the less they are disturbed the better if they are doing well, since it is only when long-established that they form first-class specimens. Hence, if any shifting be required, the ball should be kept as intact as possible, while if of the *Polypody* or many-footed, persuasive wide pans are better than deep narrow pots, as the creeping rootstocks require room to spread. A little mulching of good leaf-mould is beneficial, representing as it does the natural provision afforded by the fall of the leafage from the

succeeded in growing it for years in a London garden by noting and acting on this fact. A large brick burr embedded in the soil represented a rock, and raising this, we planted a bunch of this Fern on the north side in the cavity left by the burr, then buried it all but the frond-tips beneath a spadeful of gravel, finally dropping the burr again into its place. Here the Fern was obviously at home, no sun reached its crown, no drought could assail it, and as for the superincumbent gravel, it simply pushed its fronds through unconcernedly in all directions as it had doubtless done many times before when slips and

class, especially since La France and its beautiful variations, such as Caroline Testout, and Duchess of Albany, Denmark, and Augustine Guinoisseau, have, by the verdict of the National Rose Society, been relegated to this section. Among other varieties of special interest pertaining to this class are Cheshunt Hybrid and Viscountess Folkestone, precious for their fragrance, the former being of great value as a climbing Rose; Kaiserin Augusta Victoria, Camoens, and Grace Darling; Bardon Job, almost a single Rose, but of exquisite crimson hue, shaded with maroon; Mr. Wm. Paul's White Lady, and her parent, Lady Mary Fitzwilliam; Madame Pernet Ducher and Gustave Regis, beautiful in bud; Mrs. W. S. Grant, finest when half-blown; Marquise Litta, and Marquis of Salisbury, greatly contrasted in form and dimensions; and those grandest, in my estimation, of all Hybrid Tea Roses, Clara Watson and Gloire Lyonnaise.

Among pure Teas, those which I find most serviceable are—Bridesmaid, of higher colour than Catherine Mermet, from which it is derived; the Bride, of similar origin, but more exacting in its requirements of climate and of soil; Anna Olivier, of more amiable temperament; and Marie Van Houtte, a lovely pale yellow, which may be regarded as one of the finest of the Teas; Perle des Jardins, of deeper colour, but having a tendency to show blooms with more than one centre; Hon. Edith Gifford, Innocente Pirola, Madame Bravy, a Rose of much sweetness, greatly under-estimated in comparison with others; Madame Charles, whereby Madame Falcot has been superseded; Madame Hoste, Madame de Watteville, and Madame Lambard; Papa Gontier, Fiametta Nabonnand, Souvenir d'un Ami, and Souvenir de S. A. Prince, Corinna, and that recently introduced, brilliantly coloured variety, Empress Alexandra of Russia.

Of climbing Roses, the finest are Cheshunt Hybrid, Gloire de Dijon, Rêve d'Or, Reine Marie Henriette, Aimée Vibert, William Allen Richardson, Turner's Crimson Rambler, and Paul's Carmine Pillar, L'Idéal, of unique beauty, but not of lasting vitality; Climbing Niphetos, and Bouquet d'Or.

The majority of the Chinas, Polyanthas, and hybrid Rugosas should be cultivated in every garden, so also should the Austrian and Penzance Briar Roses, which, though very evanescent, are productive of most brilliant artistic effects. Of these the most beautiful are Rosa Harrisoni, the Austrian Copper, and Lady Penzance. *David R. Williamson.*

THE SAN JOSÉ SCALE.

FRUIT-GROWERS of this country, who have been somewhat anxious lest they should have a visitation of the San José scale insect, which has made such depredations on fruit grown on the vast American continent, will find something reassuring in the opinion that has been expressed by such an eminent authority on the subject as Mr. R. Newstead, the curator of the Grosvenor Museum, Chester. The other day Mr. Newstead was invited to attend the Board of Agriculture at Whitehall, and advise the officials as to the dangers of a visit from this pest, and he was able to fully satisfy them that the insect had not established itself in this country either upon fruit-trees or cultivated plants of any kind, whether grown in the open air or under glass, or upon indigenous plants. Mr. Newstead's opinion is entitled to the fullest consideration, for it is based upon many years of practical experience in plant and fruit culture, and nine years of scientific investigation of the injurious insects of this country.

As to the appearance of the pest in this country on imported fruit, Mr. Newstead has neither heard of nor seen instances of it, although he has made careful search for it at Liverpool, Chester, and elsewhere. He is not prepared to deny the possibility of its being brought over on fruit, but he feels confident that the chances of its ever establishing itself in this country by such means are very remote. He thinks the insect is much more likely to be brought here on imported plants, and he suggests that such

consignments should in all cases be placed in quarantine, and rigorously inspected by experts. In any case, however, he feels that the whole matter is nothing more than a scare, and that the pest is no more likely to thrive in this country than the Colorado-beetle, the Hessian-fly, or locusts, &c. In this opinion he is firmly supported by the Entomological Society of London, before whom also Mr. Newstead gave his experience. *Liverpool Evening Express, March 10, 1898.*

ODONTOGLOSSUM CRISPUM.

YOUR advertising columns have this month already announced the fact that on several recent or early dates some 6000, 8000, 15,000, and yet again other large consignments of the Pacho varieties of *Odontoglossum crispum* would be offered for sale at Messrs. Protheroe & Morris' famous rooms in Cheapside. This matter, surely enough, should set one wondering whether the stock of *O. crispum* is so near exhaustion as we were led a few years ago to believe; or whether the collectors are endeavouring to make such a clean sweep this time, that for a few years to come at least, there will be little likelihood of such enormous consignments being sent to Europe, as would seem to have arrived during the last few months.

I remember well Mr. H. Blunt coming down from the Messrs. Low & Co., Clapham, to Mr. J. Day's, to inspect the different species of *Odontoglossum* then included in the collection, so that he might see *O. niveum* and *O. Pescatorei*, of which there were just two plants of each species in the collection at that time.

I have before me *Warner's Select Orchidaceous Plants*, and the seventh plate of that superb work is of *O. niveum* major, from this famous but now defunct collection. The twenty-fifth plate of the same volume represents a good spike of *O. Pescatorei* that was exhibited at South Kensington by Messrs. J. Veitch & Sons, of Chelsea, in the spring of 1863. In the description that accompanies the plate, it is stated that "a plant, strong and vigorous, was grown in the collection of T. Dawson, Esq., Meadowbank, that had borne branched spikes with fifty flowers." I mention these, however, to show the great rarity of the finer varieties of *Odontoglossums* when the first collectors went to Bogota, the region of the Magdalena river, the Pacho district, or any other spot likely to reward their quest. Since that time what enormous quantities have come over of both *O. crispum* and *Pescatorei*! And to-day the question naturally arises, where are they? Are the finest plants now met with, those that have been under culture for ten, fifteen, or twenty years? Can many collections show good specimens of the plants that H. Blunt sent over? or are there many pieces still in culture which Chesterton collected? I fear not; most of those early ones grew well for a time, then not quite so well; then may be the plants changed ownership, or a fresh grower had them in charge, and so on, occasional improvements taking place with recurring relapses, until a fresh consignment gave opportunity for the purchase of 50, 100, or a greater number; then the collection was considered to be improving, because the cultivator had in his hands a number of the plants possessed of natural vigour that he did his utmost to develop, and with some little knowledge, achieved better results that extended over a considerably long period of time.

But are these two species even now so universally well grown as to lead one to say there is nothing more to be learnt? It would certainly seem to me there is yet something that cultivators may learn; but the crux of the matter is, what is that particular treatment which is so essential to the continued well-being and constant improvement of these plants? I venture to say that most growers can remember good collections that have come under their observation, or fine housefuls of which they have had charge, but when dispersed, what has become of them? or if a collection has remained intact, do the original plants still exist? Whether it is the houses in which the plants grow (and these vary enough in many gardens), or the special kind of treatment afforded the plants, there

would still be the lack of a certain method of treatment whereby uniformly good growth and vigour can be assured.

It is certainly worth while inviting an expression of opinion from some of the leading Orchid-cultivators of the country which might throw light on this matter, especially as to the aspect of houses, whether span-roof, lean-to, or half-span, the kind of staging or bed on which to place the plants, dealing also with moisture, shading, syringing, and all other essential points. The subject of earth *versus* stone or tile-floors; of open rain-water and water-tanks. In the interest of the thousands of plants of *Odontoglossums* now passing into the hands of many who have not as yet had much experience with these lovely plants, some such expression would, I venture to say, be most acceptable, and likewise be of assistance to the older practitioners, enabling them to decide if the term degeneration is the correct one to apply, or whether it be not natural decay that is brought about by unnatural treatment. *W. Swan, Bystock.*

ODONTOGLOSSUM CRISPUM

"BARONESS SCHRODER" (fig. 66).

THIS, the grandest of the crimson-purple blotched varieties of *Odontoglossum crispum*, was shown by Baron Schroder at the Royal Horticultural Society on June 12, 1894, when, although a very tiny plant indeed, it created a great sensation, and secured a First-class Certificate. At the meeting of the Royal Horticultural Society on March 8 last, the plant was again shown, and it gave evidence of the good treatment received at the hands of Mr. H. Ballantine, Baron Schroder's gardener, both in the increased vigour of the plant and its magnificent and richly-tinted flowers. So much were the members of the Orchid Committee impressed by it that they unanimously recommended a Gold Medal for it as an extraordinary exhibit. It is usual to think of varieties of *O. crispum* as being white, with more or less colour in the spotted forms; and in this case too, the ground colour of the flower is white, but from the predominance of the rich crimson-purple blotches, it presents itself as a coloured rather than a white flower. In its section there are but few, and the nearest allies are *O. c. Franz Masereel* and the beautiful *O. c. Ashworthianum* of Elijah Ashworth, Esq., and which was illustrated in the *Gardeners' Chronicle*, February 15, 1896, p. 197.

METHODS OF PROPAGATION.

(Continued from p. 66.)

CORMS AND BULBS.—Though the trade florist looks to Holland for his yearly supply of Dutch bulbs, so called, yet there are some which he can not only grow at home, but in many cases grow better than the foreigner. One of these is the *Gladiolus*. Early in my trade career, the chief, if not the only mart for these handsome autumn-flowering plants was Paris, where the Verdiers, of Rose fame, and Messrs. Vilmorin, had the monopoly of the varieties raised by that industrious and painstaking hybridist, Souchet, then head gardener to Napoleon III., up to the period when he unfortunately went "Nap" for the last time, and failing, was obliged to flee the country.

The first *Gladiolus* reached us from Southern Europe about the middle of the sixteenth century, and the Byzantine form nearly half a century later, while it was not till 1751 that we got the first instalment of the thirty kinds indigenous to the Cape of Good Hope, and not till a quarter of the present century had passed did we get the other varieties, including *ramosus*; but when the supposed progenitor of the florist's *Gladiolus* "*gandavensis*" reached our gardens [W. Olbers Focke, in his *Mischlinge* (hybrids), gives *G. oppositiflorus* and *G. psittacinus* as the parents, the cross being effected in the Duc d'Arenberg's garden in Brussels, and the plants sold to Van Houtte. Other authorities give *G. psittacinus* and *G. cardinalis*, but no one has succeeded in making this cross. Herbert, Belfield, and Bidwill

believed the first-named cross to be the right one. Ed.] I know not, but its name would indicate that it came from Ghent, the great horticultural emporium of continental Europe. Now, Mr. James Kelway, of Langport, Somersetshire, sends out at least a dozen new varieties yearly, most of them dubbed with the classical names of which he seems so fond. Many of these obtain First-class Certificates from the Royal Horticultural Society, and there is a limited demand for them; and when the advance is very marked, and the variety novel and particularly attractive, the demand greatly exceeds the supply. Alas! it sometimes happens that after the bulb has flowered and obtained honours it fails to produce bulbils, and in some cases to break—that is, to produce more than one bud to the corm. The fortunate owner, when planting-time comes in March, examines the

Another way to propagate the plant is by means of seed, but it must be borne in mind that by this method the reproduction of any particular variety cannot be assured, as the tendency is constantly to sport, even when the flowers have not been cross-fertilised by man, this being nearly always effected by insect agency. Nevertheless, good seedlings are always in demand, and command a better price than mixed named sorts, there always remaining the off-chance that the purchaser may be the lucky raiser of a good one, and the interest attaching to the culture of *Gladiolus* is thus doubled. The seed, especially by some varieties, is freely produced. As soon as the seed-vessels begin to burst, the latter should be gathered, and laid singly in shallow boxes or baskets, exposed to the air, when they will open and the seed be easily secured. Thoroughly harvested, these will

the seedlings will need no further care, except to be kept free from weeds, and occasionally watered if the summer be a dry one. Thus treated, they will keep growing up to November, but it is safer to begin to dry them off before this by replacing the lights, and withholding all water. The little corms will now gradually ripen, and may be got up as soon as the leaves begin to turn yellow, and hung up by the grass in bundles, to dry off gradually, on the back-wall of a vinery. Any wet day they may be cleaned, the dead foliage cut away, and the ripe corms stored in an airy place, where frost cannot reach them. Planted out early the next year, a few will throw up a short spike and flower late in the autumn, but the majority will not produce a flower till the next or third year from sowing the seed.

It may here be noted that the first spike from a seedling *Gladiolus* is generally a grand one, both in length, pose, and size of flower, this being one of the reasons why the raisers make such a grand display at the Crystal Palace and other autumn shows, their acres of seedlings then being in fine flower. The other sections of the *Gladiolus*, as the French hybrids before referred to, and all the brilliant varieties of the elegant *ramosus*; Van Houtte's exquisitely pretty dwarf early kinds of *ramosus nanus*, *Gladiolus Colvilli*, and its useful white sport, the *Bride*, reproduce themselves by budding or offshoot corms in quite sufficient numbers for ordinary use, but may be propagated in the same manner as the *Gandavensis* section if desired.

Not only will all these last force easily, but I gather from the initial number of the *Weekly Florists' Review*, that the lovely variety *Shakespeare*, raised by M. Souchet, always one of the earliest to flower, and an older but very third-rate kind, named *Madame Monneret*, as well as one of the yellows emanating from *G. trimaculatus*, named *Isaac Buchanan*, force well and easily. *Experience*.

(To be continued.)

FLORISTS' FLOWERS.

CHRYSANTHEMUM "PRINCESS BLANCHE" AS A LATE FLOWER.

THIS variety does not seem to me to be shown the amount of favour by gardeners of which it is deserving as a late-flowering variety. *Princess Blanche* is undoubtedly one of the best from Christmas until the end of February. I had on February 20 some flowers in excellent condition. I do not say that these are large, mine being only of medium size, but for usefulness *Princess Blanche* is a capital late variety. The flowers are of a very pale blush tint, changing to pure white when fully expanded. My cuttings were rooted in February, 1897, and potted on as they seemed to require it, but they were not housed until November, being then well advanced. The plants were kept very cool, short of frost entering the house, until the flowers began to expand, when they were given a little warmth in order to assist their opening. *J. H.*

FRENCH ASTERS.

The best type of this Aster (and one might go the length of saying the true form of it) is what is known as Truffaut's *Pæony*-flowered, with the petals imbricating, or, perhaps more correctly, incurving to the centre. But it has been noticed of late that exhibitors of Asters at flower-shows, and especially at those in the West of England, where Asters are grown remarkably well, consider all flat-petalled types to be French Asters, with the result that the larger Comet varieties, which can be grown to a good size without much difficulty, are driving the true French variety, and the symmetrical Victorias also, out of the field. The Taunton Horticultural Society, observing this tendency, have wisely modified their classes for Asters, and they are excluding the Comet type from their competitions for French Asters, and require that the Comets be shown by themselves. It would be a pity if the incurving French Asters of Truffaut's type were to pass out of cultivation. They are as distinct in character as they are handsome in appearance

FIG. 66.—*ODONTOGLOSSUM CRISPUM* "BARONESS SCHRODER": PURPLE SPOTS ON A WHITE GROUND. (SEE P. 164.)

corm, and if he find that there are two or three buds bursting through the solid substance of the corm, underneath the enveloping skin, he takes all this off, and then with a sharp knife divides the corm into as many pieces as there are buds, at the same time rubbing off all the little cormlets found at the base of the corm among the dead roots, and plants the pieces in a prepared bed, sows the cormlets in boxes or seed-pans, points upward, and so multiplies the variety.

Although not exalted to the height of a florist's flower, there are now at least 1,000 distinct varieties in commerce, including the new hybrids of *Lemoine*, included in the *Lemoinei* and *Nanciensis* sections.

It follows, therefore, that the *Gladiolus* is included in all the schedules of autumn shows, and the demand has in consequence grown constant for good kinds, while the flower-spikes are so useful and lasting when cut for decoration that florists are compelled to grow them.

keep till the sowing-time, which is generally February. My practice is then to rub off the wing of the seeds between the palms of the hand, and to fan away this light chaff, leaving only the kernels of the seeds, as they may be termed.

When sowing, make up a shallow hot bed, and cover it when partly settled with 6 to 8 inches of good mixed soil, enriched with well-decayed manure, and rendered light and porous by sharp sand. On this draw drills 3 to 4 inches apart, and 1½ inch deep, sow the seeds thinly therein, covering with fine soil and pressing firmly.

If you have one to spare, put a frame and lights over and keep close, otherwise cover with old mats. As soon as the little grass-like cotyledon (seed-leaf) pierces the soil, give air during the day but close up at night, and water in the morning whenever the soil looks dry, the object being to keep the little seedlings constantly growing.

By June the lights may be removed altogether, and

and they show a range of striking colours certainly not to be found in the Comet type, and scarcely in the Victoria; but they must be well cultivated to obtain large, handsomely, and regularly incurved, and brilliantly-coloured blooms.

As the type originated with M. Truffaut in France, it has a good claim to be recognised as the true French Aster. The term German Aster should properly be modified by the addition of the qualification quilled, for that is what is really meant. The quilled Asters, when a good strain is well grown, are really beautiful, delicate, symmetrical, and attractive. Of taller and more spreading growth than the flat petalled varieties, they are yet very free, and admirable for cutting, generally flowering on long, erect stems. To obtain a proper representation of Asters in a cut state, there should be distinct classes for the quilled, the incurving Truffaut's French, the Victoria type, with their large full blossoms, symmetrical in form, and having recurving flat florets; and the Comet. This would comprise the best types. The crown-flowered type, which has a white centre, and an outer margin of some colour other than white, appears to have become less popular. This type had always a tendency to produce flowers with open centres. *R. D.*

EPACRISES.

AN exceedingly interesting and elegant genus of plants, all the species of which are natives of the warm temperature of Australia, and furnished like the Ericas of South Africa with linear leaves. The plants are very ornamental, and have long been inmates of our gardens, although to a less extent now than formerly. The different species are easily cultivated in the cool greenhouse, and they are not subject to attack from insects—in itself a great advantage.

Although the plants are mostly cool-house subjects, they bear gentle forcing when growth has started, and also to bring them into flower. Where a fairly large number of these plants are cultivated, some of them may be had in bloom early in the New Year by selecting such as make early growth, and which was ripened in the full sun in the open air the previous summer. It is good practice to stand the plants after growth has been made under glass in beds of fine coal-ashes, or gravel, in the middle of the month of June. The varieties which have an upright habit are those that I have found are the more suitable for flowering early, whilst those that possess a scandent habit are trained on a trellis of wire-work, being less severely pruned than those.

The plants should be allowed to go generally out of bloom and then be kept rather drier, but not dry for a fortnight, and at the end of that time cut back pretty severely in the case of the non-scandent species, and allow to make a break in a close cold frame, putting them into a house with a temperature of 55° by night, and 65° to 70° by day, and syringing them, and encouraging them to make growth.

The commencement of growth marks the most suitable season for repotting, surfacing, &c., although in the case of young plants from which flowers are not required another shift may be afforded late in July. A plant should never be afforded a pot that is larger than the old one by more than one inch in diameter.

Great care should be taken with the drainage, which should occupy one-sixth of the depth of the pot; and this, and the latter should be either clean or new. As a potting soil, choice fine partially-decayed hard fibrous peat, not too finely broken up and not sifted, coarse silver sand or well-washed road-grit, and some nodules of charcoal or of sandstone. Pot firmly, using a rammer, and be sure that the soil reaches down to the crocks and is made close and firm from bottom to top. Leave ample provision for affording water. Usually a quantity of weak shoots occur in the centre of the plant which are of little use, but which hinder the ripening of the chief shoots, and this thin spray should be removed before being potted. For a short time afterwards the repotted plants should be kept rather close, inuring

them gradually to air when it is seen that roots are freely penetrating the new soil.

Propagation is effected by means of cuttings and seed. Seed may be sown in early autumn and in spring, and cuttings may be inserted at the former season. Half-ripened shoots should be employed as cuttings, cutting them square across, and clipping off the lower leaves closely with a pair of scissors. Having prepared cutting-pots by well crocking them and filling them with sandy peat, take care to place small nodules of peat an inch deep over the crocks. In this case the soil and sand should be finely sifted, care being taken to cover the crocks with a layer of the coarser sifting, 1 to 2 inches deep, and finally to place a layer of the cleanest (washed) silver-sand on the top. The cutting-pots should then be afforded water, and in an hour the cuttings may be put within an impression made with the edge of the bell-glass that will be used to cover them. A slight amount of water with a fine rose should be given to settle the cuttings.

I have been very successful in striking cuttings by plunging the cutting-pots to the rims in a half-spent hot-bed. The bell-glasses should be removed twice daily and wiped dry, and when it is seen that the cuttings have begun to grow, the glasses may be tilted very slightly at first, and finally removed entirely. The rooted cuttings may be potted in thumbs, the utmost care being taken not to injure the hair-like roots in the process. A shelf near the roof-glass in an intermediate temperature will suit them till they become established, when they may be removed to cooler quarters. In raising seedlings, new forms of flowers and new colours may be expected, a probability which makes seed-sowing so interesting. *H. T. M., Stoneleigh.*

THE WEEK'S WORK.

THE FLOWER GARDEN.

B. H. WALTERS, Gardener, Eastwell Park, Ashford.

Delphiniums and Shrubby Varieties of Phloxes may now be planted or transplanted in beds or borders. When clumps of Phloxes have grown to a large size, as they will in the course of three or four years, they should be dug up and divided, the central parts being chopped out and thrown away. This, although a ready means of increase, is not the best to take to obtain fine heads of flowers, and the surest method of securing the latter is by means of autumn-struck cuttings. These should be struck singly in flower-pots of 3 inches in diameter, or half-a-dozen together in a 6-inch pot, wintering them in frames. The land to be planted with Phloxes should be heavily manured, deeply dug, and well drained, for although the plant needs much water in hot weather, the surplus should pass freely away. Delphiniums may receive nearly the same kind of treatment, excepting that less manure should be employed; and the roots and rootstock being very brittle, greater care is necessary if division is resorted to. The small bits broken off, if furnished with a bud, should be grown on in the reserve garden, not planted in the herbaceous plant border, where they are likely to suffer from crowding. I need not specify varieties of either plants, these being found in great variety in most nursery catalogues.

Primula Polyanthus.—If an increase in the stock of this useful spring-flowering plant is required, seed should be sown now, and onwards till May, in boxes filled with moderately light soil under glass, and carefully afford water. The seed takes some time in germinating, and the soil is liable to turn sour if afforded water excessively. When large enough to be handled, prick out the young plants into boxes, or a frame placed over a spent hot-bed, and plant out in the reserve garden. *Primula polyanthus* resents often removal, and should therefore be assisted by surface dressings of manure in a rotten state and fresh soil, when it is seen that leaves and flowers grow smaller.

Bedding Plants.—The seeds of *Lobelia erinus* varieties; *Pyrethrum*, aureum fol. var.; *Phlox Drummondii*, German and China Asters, Ten-week and East Lothian Stocks, *Zinnias*, *Marigolds*, *Centaurea candidissima*, *Cineraria maritima*, *Perilla nankinensis*, *Petunias* both single and double-flowered, and many others, may now be sown in mild

heat in beds, boxes, pans, and pots. Examine them closely when appearing above ground, and guard against damping. *Zinnias* are very liable to damp-off, and it is best to prick them as soon as they can be handled into frames or boxes. Continue the propagation of such plants as *Alternanthera*, *Lobelia*, *Iresine*, *Coleus*, *Dahlia*, and *Mesembryanthemum cordifolium variegatum*, till the number of plants required has been obtained.

Gladiolus.—Providing the spots where these plants are to flower have been manured slightly and deeply dug, corms may forthwith be planted. If the soil be heavy and retentive, place a handful of sharp sand in the hole previous to putting in the corm. Let the corms according to their size be planted from 4 to 6 inches deep, making the soil pretty firm around them; and arranging them in lines, groups, or beds. If a robust-growing plant, with brightly-coloured flowers, is what is wanted, plant the variety *Brenchleyensis*. This variety contrasts admirably with *Hyacinthus candicans*. *Gladiolus* are very suitable for planting among dwarf shrubs. Those who take especial care of their *Gladiolus*, or those who grow for exhibition, start the corms in pots, which they place in the greenhouse or cold frame, planting them in the open in early May; and this is undoubtedly the better plan if space can be afforded.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Tomatos.—In order to keep pace with the demand, every available means should be adopted, and Peach-houses, after the fruit of the latter is set, may be utilised for Tomatos, planting them against vacant spaces on the trellises and sunny walls. The plants may be grown in 9 or 10-inch pots, or in mounds or ridges of soil placed on the Peach borders; and planting in this manner does away with the making of holes in the borders, perhaps to the injury of the roots of the Peach-trees. The soil may consist of three parts loam to one of rubble. On finishing the planting, afford a moderate amount of water, and secure the stems to the trellis, or to a stake, with a broad piece of bast.

The Grape-room.—After this time artificial heat will only be required in damp, dull weather, applying heat at 9 A.M., and ceasing to use it at 12 noon, affording ventilation by the upper windows, and shutting up early in the afternoon. On fine sunny days, no fire-heat will be required, and the upper ventilators may be opened at 8 A.M., and the room closed before sunset. Examine the water in the bottles occasionally, adding more where necessary, and keep the bunches free from decaying fruit, and do not sweep the floor or cause dust to rise and settle on the bunches.

Strawberries.—Maintain the supply by a regular introduction of fresh batches of plants, placing the plants on shelves and stages near the glass, and generally carry out the directions given in earlier calendars. If the plants can be kept out of vineries the chance of red-spider being communicated to Vines is much lessened, but in many gardens there is no choice. At this season, Strawberries should be closely attended to, water being afforded at short intervals in accordance with the stage of growth. Those plants on which the fruit is swelling require water in liberal quantities as sun-power increases, and on hot days water may be required twice; air should be afforded as freely as is consistent with progress, and the syringe not used during flowering. Fumigate or vaporise if aphides are present, and do not omit to thin the bunches of fruits at an early period. Strawberries to be sent by rail or other conveyance should be packed one layer deep in shallow boxes, using soft moss, the finest wood-wool or wadding at bottom and top, with a soft Bean or Vine-leaf wrapped round each fruit. Pack closely, but not so as to bruise.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Palms.—The necessary cleaning and repotting of these plants should receive attention at this season, and may be carried on till May and June, if warm-house accommodation be available. If the plants are not infested with scale, weak soft-soapsuds or paraffin emulsion—I prefer the latter, as it heightens the colour of the foliage—may be used in sponging the plants. If scale be present, as is probably the case, the wash must be stronger, and it is advisable to syringe such plants that are about to be cleaned with the above solution as a beginning, in order to

render the dislodgment of the scale less difficult. Palms should not be retubbed or repotted unless they require more root-room, to get rid of stilt roots, or the soil is exhausted, or the drainage defective. Top-dressing may be used on plants not requiring repotting, this being kept in position by a ring of zinc or lead. A number of young Palms should be kept in small pots for table and room decoration. If the soil is in a bad condition, wash it all away from the roots and repot in fibrous loam two-thirds, and leaf-mould one-third, and enough coarse silver-sand as will render the mass porous; pot firmly, working the compost among the roots, and by the side of the pot. The drainage should be good, and fairly abundant, and be well covered with the fibry parts of the loam. Palms that have suffered much root disturbance, or which have been root-pruned, should be afforded bottom-heat till re-establishment has taken place.

Ferns.—Fern spores, whilst in good germinating condition, may now be sown on sterilised lumps of peat, or peat and loam, placed in pots half filled with crocks, and kept moist by sprinkling with a very fine rose-can. It is well to cover the pots with *cloches* or bell-glasses, or hand-lights. Greenhouse species need cool treatment, and exotic Ferns from warm countries stove treatment. When the seedlings appear, remove all shading material, and only make use of it against bright sunshine. Any of the exotic warm or greenhouse species in need of repotting or top dressing should now receive attention, and if more of them are wanted, most of the species may be readily increased by division of the root-stock. As a potting-soil, fibrous loam, peat, leaf-mould, in about equal ratio, with some coarse silver-sand and small nodules of charcoal suit most of the species. As in the case of Palms, the pots should be clean inside and out, and the drainage sufficient. The fernery may at this season receive a general overhauling and cleansing, removing dead fronds, filling up vacant spaces with suitable species, and introducing, where space permits, Palms, Cycads, Phormiums, Begonias of the Rex type, Saxifragas, Aralia Sieboldi, Ophiopogons, Ficus repens, &c. Make up anew the pockets and ledges where the soil is washed away, using lumps of turfy loam and peat, sprinkled with plenty of sharp sand, and let the fernery be kept moist and and rather warmer for a short time, in order to get the plants into growth.

THE KITCHEN GARDEN.

By J. W. MCHATTIE, Gardener, Strathfieldsaye, Hants.

Second Early Peas.—The ground selected for these should have been well prepared in the manner recommended on p. 83, Feb. 5th. It should have been deeply trenched and also enriched with manure. It is good practice to sow tall-growing sorts in rows 5 feet apart, and to crop the intervening spaces with Early Turnips, Dwarf Cauliflowers, Cabbages, or Lettuce. Sufficient space is a very important circumstance in securing an abundant crop. Tall varieties that may be recommended for present sowing are, Duke of Albany, height 5 feet; Prodigy, height 5 feet; Telegraph, 5 feet. Marrowfat Peas not exceeding 3 feet in height are, Dr. McLean, Boston Unrivalled, and Fillbasket. Valuable Dwarf Marrowfat sorts also for present sowing are, Stratagem, height 2 feet; the Daisy, 2 feet, and Sutton's Dwarf Defiance, 2 feet.

Asparagus Beds.—If the beds were covered last autumn with a top-dressing of rich manure, the less decayed parts of same may now be removed. Then afford the beds a dressing of bonemeal, and point the manure and bonemeal into the soil $2\frac{1}{2}$ inches deep, which will loosen the soil, and give the heads more freedom to come through. Care must be taken, however, not to disturb or injure the plants if near the surface. When the beds have been so forked, give them a top-dressing of common salt, rake them over neatly, and fork up the alleys.

Sowing and Planting Lettuce.—All varieties of Lettuce will succeed if sown now on a border which has been richly dressed previously with rotten manure. Sow the seeds in rows 9 inches apart, or in beds 4 feet wide, and cover the seeds half an inch deep with fine soil. Some good Cos varieties are Bath or Brown Cos, Mammoth White Cos, and Carter's Giant White Cos. Of Cabbage-Lettuces, the best are Early Paris Market, Commodore Nutt, Neapolitan, and Perfect Gem. Where there has been any difficulty in growing large and crisp Cos Lettuces, I would advise a trial of the Cabbage varieties. These, if grown quickly, and with plenty of moisture, are excellent in every way. Lettuces that have been wintered in handlights may now be lifted and planted in the open border. Handle the plants carefully,

and plant them from 9 to 12 inches apart, according to the sorts. Do not expose them to the air more than is necessary, the young roots being easily damaged by cold winds or strong sunshine. Afford air on fine sunny days to Lettuce plants in frames, and close the frames early in the afternoon with a temperature of 60° to 70° , giving the plants at the same time a slight spraying with the syringe. The night temperature should be kept as nearly as possible at 45° to 50° .

Work that should be hastened.—If from any cause Onions, Leeks, Parsnips, Broad Beans, Early Potatoes, Early Carrots, Radishes, Spinach, and Peas have not been sown or planted, no time should be lost before this is done.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Odontoglossums.—Such cool-house species as *Odontoglossum Edwardii*, *Oncidium macranthum*, *O. serratum*, *O. monachicum*, *O. undulatum*, *O. superbum*, *O. Leopoldi*, *O. lamelligerum*, *O. Loxense*, and *O. zebrinum*, being now in growth, any that require re-potting, and which are not showing flower-spikes, may be attended to in this respect. In order to afford sustenance to those showing flowers, carefully pick out some of the old compost, and afford fresh in its place. These species prefer a cool, shady part of the house, and moisture-laden air, and if all of them be placed in a group together, it becomes an easy matter to afford the proper conditions by syringing between the pots twice or thrice a day, according to the state of the weather. At this season, those plants having flower-spikes require copious applications of water at the root, till such times as the spikes are removed. Plants which have gone out of flower should be placed altogether, in order that they may be treated differently to the other plants, and kept rather dry, which will enable them to rest, but the atmosphere around them must be moist. Such as have flowered strongly, will in most cases have slightly shrivelled, but it is an error to afford these much water, with the idea of causing an immediate plumpness in the pseudo-bulbs, as by this practice the roots decay, and the plants deteriorate generally. Strong, healthy specimens frequently send up two flower-spikes from one pseudo-bulb, but consideration for the future of the plant demands the removal of one of them, and from the side where the leaves are the shortest, the best spikes being usually produced from the axils of the longest leaves. Slugs and woodlice cause much injury to the growing tips of roots and to the spikes, and the cultivator should examine each plant every night by lantern-light, in order to discover and kill these pests of Orchid-houses. *Odontoglossum Madrense* and *Colax jugosus*, if placed in a well-shaded position, grow well in this house. The latter is now showing for flower at Burford. Both species should henceforth be well supplied with water.

Cymbidium Mastersii, or *C. affine*.—If any plants of this species require repotting, it should forthwith be carried out. Let the pots be rather large for the size of the plants, and make use of a compost of two-thirds loam, one-third peat, with the addition of a little coarse silver-sand and a few crocks; and having done this, keep them, and those that have not been disturbed, in a moist state, and well protected from strong sunshine, and their foliage will remain fresh and clean, and strong growths will be made. *C. eburneum* may be repotted within a fortnight after flowering has ceased.

Masdevallias should now be showing flower; and although these are moisture-loving plants, the compost must not be kept in a saturated state. Species such as *M. Wagneriana*, *M. melanopus*, *M. ludibunda*, *M. infracta*, *M. hieroglyphica*, *M. Armini*, *M. gemmata*, *M. Gelseniana*, *M. Estradae*, *M. caudata* (Shuttleworthi), *M. Courtauldiana*, &c., which are dwarf, should be cultivated in pots placed on a stage, but afterwards suspended near to the roof-glass when their flower-spikes show, which will tend to give strength to the spikes, and allow the plants to be seen to advantage. *M. bella*, *M. Chimera* and its varieties, *M. Wallisii*, *Winniana*, *Gongora*, *Roezlii*, *stupenda*, and *Backhouseiana*, should be similarly treated. The present is a suitable time for rebasketing or surfacing these species, and those that are well established in a compost that is in good order, may have a few heads of sphagnum-moss pricked in over the surface. Repotted plants must be afforded water with discretion till plenty of roots are made, or spotting of the old leaves will occur. The plants should be held over a tank occasionally, and well syringed on the under-side of the leaves.

Habenaria rhodochila.—This plant is starting to grow in the warm-house, and it may be repotted without delay in long thumbs, one tuber in each, filling around the tuber to half its height with crocks, keeping the top of the tuber just below the rim of the pot, and above the crocks use the following compost: one-half fibrous peat and loam, one-half finely-chopped sphagnum-moss, some finely-broken crocks, and a small quantity of coarse silver-sand, the whole being first well rubbed together. Let the materials be firmly packed round the tubers, and place in a warm, growing temperature, and lightly sprinkle the compost whenever it becomes dry, gradually increasing the amount of water after growth has begun. When the points of the new growths are seen pushing up through the new compost, it is of importance to raise the plants up to the roof, otherwise the flower-spike will become weak. *Habenarias* thrive in full light without direct sunshine. Other well-known varieties, as *H. militaris*, *H. Susanna*, *H. intermedia*, *H. galeandra*, *H. longecalcarata*, *H. carnea*, and its variety *nivosa*, may likewise be repotted, and treated exactly as recommended for *H. rhodochila*.

THE HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Raspberries.—Such of the canes as were left at their full length when fastened to the supports should now be shortened to a point 6 inches higher than the stake or wire to which they are secured; and Raspberry-caness recently planted may be cut down to within 6 inches of the ground, to cause strong shoots to be thrown up this year for fruit-bearing next year, as, if left at their full length the year of planting, a few small fruits are borne, and then the plants die, there being not enough vigour in them to perfect fruits, and produce young canes at the same time. The young shoots that spring from the cut-down canes should be reduced to two when grown 2 inches in height.

General Remarks.—Recently-planted fruit trees, having settled down together with the soil, may be pruned forthwith, and the trees made secure with ties or shreds and nails. The pruning consists this time of removing weak shoots, and cutting the others back to about one-third of their length. It is usual for the shoots, when left of their full length, to form fruit-buds only the first year instead of growing, rendering it necessary for the cultivator to cut these self-same shoots hard back the next year, which is so much time lost. In pruning a shoot, cut to an outside bud, and one that points in the direction the branch should take. Attention to this point is very necessary when laying the foundation of the crown. If mulching was placed over the roots, it should now be removed, so as to allow sun-heat the more readily to penetrate the soil, some fresh materials being used if the heat of the summer seems to demand a fresh mulch. A crumbly, friable state of the soil is almost as good as a mulch in retaining moisture in the soil, and much more favourable to the ingress of heat, and consequently of air and water. The opening of the blossoms of fruit trees of all kinds, which are very abundant with the exception of Plums, has been beneficially retarded by recent frosts in the midlands and doubtless elsewhere. The bullfinches are getting troublesome, especially in pecking out the buds of the Plum, and the gun must be used against them. If covers are used to protect Peach and Apricot trees, do not let these remain down an hour longer than is necessary during the hours of daylight, but cover the trees every night for the present. Trees that are aged, or which consisted of undesirable varieties, and were regrafted with others last year, should receive attention; and if the scions are seen to have made strong growth, remove all the remaining old branches; but if the scions are weak, some of the branches of the stock should remain for another year, so as to maintain healthy root-action. Do not let any scions that are laid-in get dry, as they are apt to do when bundles of them are laid-in, but either spread them in a thin row, or afford water, and cover the adjacent soil with moss. Pruning should now be brought to completion, and the soil over the roots loosened.

COTONEASTER.—M. ZABEL, of Gotha, has published, in the *Mittheilungen der Deutschen Dendrologischen Gesellschaft*, a monograph of the genus *Cotoneaster*, in which are described twenty-four species.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

APPOINTMENTS FOR THE ENSUING WEEK.

MEETINGS.

MONDAY, MARCH 21—National Chrysanthemum Soc. Adj. Ann. Meeting, at Anderson's Hotel, Fleet St., at 6 P.M.
TUESDAY, MARCH 22—Royal Hort. Soc. Coms.
WEDNESDAY, MARCH 23—Torquay Gard. Assc. Spring Sh.
SATURDAY, MARCH 26—Royal Bot. Soc. Gen. Meet.

SALES.

MONDAY, MARCH 21—Hardy Perennials, Iris, Begonias, Cannas, Roses, &c., at Protheroe & Morris' Rooms.
TUESDAY, MARCH 22—Imported and Established Orchids, at Protheroe & Morris' Rooms.
WEDNESDAY, MARCH 23—Japanese Lilies, Tuberoses, Gladioli, Roses, Begonias, Hardaceous and Hardy Border Plants.
FRIDAY, MARCH 25—Stove and Greenhouse Plants, Roses, Shrubs, and Border Plants, at Stevens' Rooms.
FRIDAY, MARCH 25—Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—43° 7'.

ACTUAL TEMPERATURES:—

LONDON.—March 16 (6 P.M.): Max., 55°; Min., 47°.
PROVINCES.—March 16 (6 P.M.): Max., 53°, Aberdeen; Min., 46°, Shetland.
Mild, slight rain; dull.

A CASE of very great importance to market gardeners and nurserymen, came before the Court of Appeal on Friday, 11th inst. Most of our readers are familiar with the enormous development of the market garden industry of late years. At various times we have published series of articles illustrative, not only of the great extent of this industry, but also of the methods of cultivation and marketing adopted. Speaking generally, this vast development has been effected within the last twenty, and much of it within the last ten years. As agriculture has declined, market gardening, especially market gardening under glass, has prospered, and some at any rate, of the farmers, favourably situated for the purpose, have had the wisdom to turn their attention to the culture of flowers, bulbs, &c., for market. Of course, the ubiquitous tax-collector, and his brother who gathers in the rates, took note of this increasing property, and many have in consequence been the questions put to us as to the principle on which market gardens, and especially the glass-houses upon them, should be rated. We have not been able to give a satisfactory answer, and no wonder, since in almost every court in which the case has been argued the decision of the Judge has varied. We had thought that the well-known Purser case, reported in our columns at the time, had settled the matter, but apparently that is far from being true, and now we have what will perhaps be known as the Piper Case.

Here the question at issue is, whether glass-houses in a market garden are to be rated as "buildings," or as "agricultural land," according to the terms of the Agricultural Rates Act. A divisional court decided that the "buildings" were to be treated as part of the market garden, and rated accordingly. The Surveyor of Taxes appealed against this view, and now two out of

three members of the Court of Appeal uphold the view of the Surveyor of Taxes, and have decided that buildings are not subject to the exemptions accorded to agricultural land.

This is a great disappointment to the market garden industry; but a range of Cucumbers is undoubtedly a building, and although used exclusively for trade purposes, the decision is that no "building" can be rated as agricultural land.

Probably an appeal to the Legislature may become requisite in order to modify the phraseology of the existing law. We print *in extenso* the judgment of the Master of the Rolls. Lord Justice RIGBY agreed with him. Lord Justice VAUGHAN WILLIAMS thought that although, speaking generally, buildings were not agricultural land, yet that greenhouses in nurseries and market gardens formed an exception, as agricultural land was declared by the Act of 1896 to include nurseries and market gardens. The present case is known as *Smith v. Richmond*.

THE MASTER OF THE ROLLS said:—

"The question in this case is whether glasshouses in or on a market garden are to be rated as buildings or as agricultural land under the Agricultural Rates Act, 1896.

The Court of Quarter Sessions held that the glass-houses ought to be rated as agricultural land. On appeal to the Queen's Bench Division the members of the Court were equally divided, and the appeal was dismissed, but leave was given to appeal to this Court.

The glasshouses in question are clearly buildings in the ordinary legal meaning of the word. The case stated leaves no doubt on this point.

The question turns entirely on the true construction of the Act of Parliament (59 & 60 Vict. c. 16). The ninth section contains a definition of agricultural land, but no definition of buildings, nor of market gardens or nursery grounds. The Interpretation Act, 1889 (52 & 53 Vict. c. 63), contains in section 3 a definition of land; and this word, when used in subsequent statutes, is to include buildings, unless a contrary intention appears. The Interpretation Act, 1889, contains no definition of buildings, market gardens, or nurseries.

The ninth section of the Act of 1896 clearly shows that land there cannot possibly mean or include buildings in the early part of the section; for the definition is that "agricultural land" means any land used as arable, meadow, or pasture ground only.

Market gardens and nursery grounds are, however, also declared to be agricultural land, and this is the enactment which gives rise to the difficulty with which we have to deal. The definition in section 9, however, must not be used to contradict other parts of the Act, or to introduce anomalies which the language of the enacting parts of the statute does not justify. Market gardens and nursery grounds may or may not have buildings upon them. If they have not, no difficulty arises; but if they have, then comes the question, how are those buildings to be rated? To answer this question we must look to the enacting clause, which is section 1.

Here we have "agricultural land" used in connection with, and, as I think, plainly contrasted with "buildings and other hereditaments." Similar language is used in sections 5 and 6. This express mention of buildings makes the whole statute perfectly clear to my mind; and removes the doubt caused by the use of the words "Market gardens and nursery grounds" in section 9. The only conclusion at which I can arrive is that buildings are not to be treated as agricultural land for rating purposes under this Act of Parliament.

The case of *Purser v. Worthing*, 18 Q. B. D. 818, does not, in my opinion, assist the Court in construing this Act of Parliament. That case merely shows that a market garden, *prima facie*, includes the buildings upon it used for market garden purposes. To urge that market gardens and nursery grounds do

not cease to be so because they are more or less covered with glass-houses is to urge what is quite true, but is beside the mark. The question is, how are such houses to be rated under this Act of Parliament. My answer is, if they are buildings they must be rated as such and not as agricultural land. Mr. Salter in his very able argument suggested that buildings used only for covering land which was cultivated under their protection ought to be distinguished from other buildings, and ought to be held to be agricultural land. I can find nothing to justify a distinction between one class of buildings and another for any such purpose as his argument requires. Section 5, clause c, speaks, no doubt, of buildings used only for the cultivation of land, but this clause in no way shows that such buildings or any others are to be rated as agricultural land.

The case of the *L. & N.W. Ry. v. Llandudno Commissioners*, 1897, 1 Q. B. 287, turned on the construction of a provision in another Act of Parliament, and does not really assist me to arrive at the true interpretation of the statute with which we have to deal. In my opinion, the appeal must be allowed, and the orders of the Queen's Bench Division and of the Quarter Sessions must be reversed, with costs here and below."

BOUGAINVILLEA GLABRA AT MOATLANDS, PADDOCK WOOD (Supplementary illustration). The conservatory at Mr. THOMAS BEANES' residence, Moatlands, is an unusually lofty one, as our illustration (fig. 67) shows, and offers therefore uncommon facilities for the cultivation of plants of large growth, as Palms, *Musa Ensete*, and *M. Cavendishi*, tender Norfolk Island Conifers, and rampant climbers like *Bougainvillea glabra*, the central object in the illustration. This is just one of those glorious inhabitants of the warmer temperate regions which is seldom quite satisfactory in appearance in our glass-houses, unless in great measure it be allowed to grow unrestrained. In a big house like Mr. BEANES' it suffices for the gardener to make here and there the leading shoots secure, and to guide them into parts not yet appropriated by other plants, and to remove branches and growths that tend to render the shade too dense for the other inmates. The plant is doubtless planted out in a border of rich sandy loam, and is afforded manurial aids in its season of growth and flowered. Those who have journeyed in Southern Europe and Algeria, will frequently have seen this species of *Bougainvillea* covering the sides and roofs of houses, with immense sheets of purplish-red blossoms, looking very unlike the same plant as generally seen in our English glasshouses. The photograph from which our illustration was taken, and for which we are indebted to Dr. MORRIS, was by Messrs. Lewis & Co., Maidstone.

THE ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, March 22, in the Drill Hall, James Street, Victoria Street, Westminster, 1 to 5 P.M.; and a lecture on "Soils" will be given by Mr. J. J. WILLIS at 3 o'clock.

—We are requested by Rev. W. WILKS, Sec., to state that since issuing the schedule of arrangements for 1898, the Society has received from Messrs. BARR & SONS, of King Street, Covent Garden, the offer of a Silver Cup for Daffodils, to be competed for at the Society's meeting at the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday, April 12—open to all amateurs. Notice of entry should be addressed to the Secretary, R.H.S. office, 117, Victoria Street, S.W., and must be posted on or before Thursday, April 7. Collection of Cut Daffodils (*Polyanthus* section excluded), of each of the three groups—*Magni-coronati*, *Medio-coronati*, and *Parvi-coronati*—being represented, the flowers to be arranged in bottles which will be provided by the Society. Not fewer than forty different varieties, and not more than three bottles of any one variety, to be staged. Correct naming and elegance of arrangement will be taken into account. The winner of the 1st prize will be awarded a silver Daffodil cup, designed by Mr. H. C. Moon; and that of the 2nd prize, will receive £1 10s. and a silver flora medal (given by the R.H. Society).

EXPOSITION INTERNATIONALE.—We have received the schedule of an International Horticultural and Arboricultural Exhibition which it is proposed to hold in the Jardin Parisien, near the Champs de Mars, Paris, from April 21 to May 8. The Secretary is M. H. LEMÉE, 146, Boulevard de Grenelle, Paris. The names of the members of the committee are not given, whilst those of the Presidents, honorary and acting, are not familiar to horticulturists on this side of the Channel.

SIR GEORGE KING, K.C.E.I.—The last number of *Indian Gardening* that has reached us contains a portrait and a sympathetic account of the career of Sir GEORGE KING, who has vacated the post of Superintendent of the Royal Botanic Garden, Calcutta, and of the Government Cinchona Plantations in Bengal. Cinchona febrifuge, and pure quinine are now in consequence readily obtainable at low prices throughout India, to the great advantage of the community. Great improvements have been carried out in the gardens, the result being, says our contemporary, charming to the thousands of visitors who frequent them. Of the various monographs published by Sir GEORGE KING, by the authority of the Government, we can only speak in the highest terms, as they are not only creditable to the author, but confer honour on the government. A monograph of the Orchids of Sikkim, in conjunction with Mr. PANTING, is in course of elaboration.

FERNS OF NICARAGUA.—In the *Bulletin* of the laboratory of the State University of Iowa, No. 2, 1897, Mr. SHIMEK gives a detailed list of the Ferns of Nicaragua, prefacing it with a few remarks in the course of which he says that tropical America is the "Fern-paradise of the earth." The author adopts the primary sub-division of the Filices into the leptosporangiate, in which each sporangium originates from a single epidermal cell, and eusporangiate, where they arise from a group of epidermal cells. As it is only the few who can hope to be able to verify this reference, and those few only on rare occasions, it is satisfactory for practical purposes to know that the presence or absence of a ring or annulus and its modifications are available, inasmuch as they coincide (or not, as the case may be) with the distinctions observable in the development of the spore cases.

THE ALEXANDRA PALACE, MUSWELL HILL.—This building, so long tenantless, is now undergoing a process of brightening up preparatory to being opened to the public in the spring. Among the attractions likely to be provided, a series of flower shows, on an important scale, will probably be one of them. It is stated that since the last flower-show was held in the Alexandra Palace, some 24,000 houses have been erected in its neighbourhood, so there should be no lack of public support. This fact illustrates the enormous growth of London during the past few years.

PASTURE PLANTS.—Mr. W. TOOGOOD, of the Royal Seed Establishment, Southampton, has published, through MACMILLAN & Co., a *Treatise on Pastures and Pasture Plants*, which will be found a useful summary of knowledge concerning the identification and culture of pasture plants. The treatise is well got up, and has an adequate index.

PICEA OMORIKA.—When the Servian flat-leaved Spruce was first discovered, it excited great interest among botanists, as the nearest relative was in far-off Japan, or on the mainland adjacent. Dr. WEBER now supplies an interesting link in the shape of a fossil species from the quaternary beds of Saxony. This is described in ENGLER'S *Botanische Jahrbucher*, band 24, heft iv. (1898), p. 510.

"THE CACTUS JOURNAL."—Few, if any, groups of plants have greater claims upon the attention of amateurs than have, what are broadly called, Cactuses. Their strange forms, their exquisite symmetry, their adaptation to circumstances, their frequently gorgeous flowers, their manifold interest, and their generally easy culture, all furnish reasons why these plants should find favour with cultivators. Years ago they were more popular than they are now.

Then for some inscrutable reason they went out of favour, and remained so in spite of some spasmodic efforts made by individuals to renew their popularity. Again there are symptoms of a revival of interest in these plants. A Cactus Society has been formed, indeed it is nearly three years old, and now we have before us the first monthly part of a journal to be devoted exclusively to Cacti and other succulent plants. There are always great difficulties to encounter in the preparation of a first number, which should never be looked on as a test. We presume that in this case some accident prevented the revision of the proof-sheets, and that in future more care will be exercised in the spelling of the names of plants. It will be news to botanists to learn that *Laurus nobilis*, *Camphora*, and *Cinnamomum*, are, or ever were, natives of Mexico! Photographic reproductions are well suited to bring out the characteristics of Cactuses, so that our contemporary will render good service by giving representations of the most notable species, preferably as isolated specimens, in order more perfectly to ensure the plant being in focus. We cordially sympathise with the aim and object of our contemporary, and wish it all success.

HORTICULTURAL COLLEGE, SWANLEY.—The sixth annual report of the Women's Branch is before us. From this it appears that six former students are now engaged in market gardens, eight in public establishments, nine in private gardens, three in institutions, six in teaching. Miss GULVIN, formerly of Kew, has now taken a responsible post, with several gardeners under her. Three other young women are at Kew, and two in the Edinburgh Botanic Garden.

A SCHOOL OF HORTICULTURE.—The *Revue Horticole* announces, that the department of the Loire Inférieure has received a donation of one million three hundred thousand francs (fifty-two thousand pounds) for the establishment of a school of horticulture at Nantes.

"NATURE NOTES."—Mr. G. S. BOULGER has accepted the editorship of *Nature Notes*, the April number of which magazine will be the first to be published under his directorship. Mr. BOULGER'S botanical work must be well known to our readers, and there is every reason to hope and believe that the Selborne Society's publication will glean much benefit from the services of so experienced an author.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, March 21, 1898, when a paper will be read by Mr. H. M. GRELLIER (Fellow), entitled "Tithe Rent Charge Recovery." The chair will be taken at 8 o'clock. Members hoping to join the party at Manchester, on April 20 and 21 next, are requested to fill in and return, at their convenience, the flyleaf attached to the circular-letter forwarded to them on the 7th ultimo. As regards the excursions, it should be noted that the only two that can be combined are the visit to the Sewage Works and to the cotton mills. Each of the other visits or excursions will occupy a whole day.

THE GENUS CYCLAMEN.—Dr. F. HILDEBRAND, Professor of Botany in the University of Freiburg in Brisgau, has issued a monograph of the genus *Cyclamen*. It is published by GUSTAV FISCHER, of Jena, and may be had of Messrs. WILLIAMS & NORGATE. Thirteen species are described, unfortunately wholly in German, and to the description of the species is added a detailed account of the life-history and mode of growth of the plants. Six lithographic plates serve to show the structural details of each species. The great variations that are now showing themselves in the ordinary *Cyclamen*, *C. latifolium*, are the more remarkable, in that they occur in individuals derived from one species without any hybridisation. The species are:—*persicum*, Miller; *europæum*, Linn.; *repandum*, Sibth.; *balearicum*, Rehb.; *cilicicum*, Kotschky; *alpinum*, *ibericum*, Coum, Mill.; *cypricum*, Kotschky; *africanum*, Boissier; *græcum*, Link.; *neapolitanum*, Tenore; and *Rohlfianum*, Ascherson.

THE UTRECHT BOTANIC GARDEN.—The Utrecht Botanic Garden is under the direction of

Professor F. A. WENT, and the curator is M. J. K. BUDDE. In the houses of the above institution there is a fine collection of Filmy Ferns, including *Trichomanes radicans* and *Todea superba*. In the orangery are *Schefflera digitata*, Forst (*Aralia Schefflera Spreng*), 13 feet high by 5 feet 5 inches in diameter; *Dicksonia antarctica*, a fine *Chamærops excelsa*, *Dammara robusta*, with its strange and characteristic leaves; *Ruscus androgynus*, a very fine *Litsea japonica*, some *Alsophilas*, *Acacia*, *Myrtles*, &c. In the propagating-house, I noted *Calyptrono Swartzii* and *Homalonema album*, sent from Buitenzorg; *Anemia phyllitidis*, seedlings of *Bilbergia nutans* ×, *Tillandsia Lindenii*, one of which, with drooping leaves, has a very ornamental appearance; and, in the tanks, *Cladophora ægagropila*, which grows wild in the marshes in the environs of Groningen. Many specimens of Mr. Lynch's *Cinerarias* (mentioned in the *Gardeners' Chronicle*) attract attention, owing to their value as cut flowers. Among numerous climbing plants here are *Passiflora Raddiana*, from Brazil, remarkable for the duration of the blooming season. The first flowers opened on April 17 last year, and, with some interruptions of eight or ten days, they did not cease appearing until the end of December. Sometimes, according to M. BUDDE, there were from forty to fifty blooms open at once. I would also mention *Rivinia lævis*, but, like *R. humilis*, with orange instead of red fruits. In the large orangery I found still in bloom *Chrysanthemum L'Ami Cayeux*. There were also very fine plants of *Cinnamomum camphora*, *Quercus Suber*, *Chamærops humilis*, *Eugenia rubricaulis*, *Witsenia corymbosa*, and *Greigia sphacelata*. In the tropical-house is a glazed case containing *Macodes petola* and *Anætochilus Dawsonianus*, as fine and vigorous as I have ever seen, and very creditable to the grower. I noticed also *Lycopodium dichotomum*, *Macodes javanica*, and a leafless Orchid, perhaps unique in Europe, *Taniophyllum Zollingeri*. Mr. BUDDE has succeeded in fertilising *Anætochilus Dawsonianus* with *Macodes petola*, and gathered many seeds, none of which has yet germinated; also *Phalænopsis amabilis* with *Oncidium papilio*, which has resulted in a fine seed-pod; and *P. amabilis* with *Stanhopea tigrina maxima*. In the same house are *Lycopodium hippuris* and *Phlegmaria*, *Carludovica incisa* (a fine specimen), *Clavija ornata* in fruit; a remarkable plant of *Pinanga Kuhlii*, *Gnetum gnemon*, *Alocasia cuprea*; *Liparis Rheedi*, unique in Europe; *Ophioglossum pendulum*; very large and fine *Nepenthes*, an interesting hybrid from *Vanda tricolor* by *Macodes petola*, *Phœnicophorum seychellarum*, *Cinchona Ledgeriana* from seedlings raised at Utrecht, *Coffea liberica*, and many economic plants. In another house is a specimen of *Cycas glauca*, with fifty-six leaves. There are also *Stanhopea tigrina* with wonderfully healthy leaves; grand specimens of *Oncidium sphacelatum*, *Phaius grandifolius* of unusual vigour, *Crinum augustum*, *Ceratozamia Miqueliana* (Miquel was Professor at the Utrecht University), *C. brevifrons* × *robusta*, a seedling three years old, very graceful, with twelve leaves and likely to prove a valuable market plant being both elegant and sturdy; *Livistoni moluccana*, *Musa sapientum*, *Cycas revoluta*, some *Bromeliads* and *Dioon edule* are also there. In the Palm-house the following are worth special mention: *Dracaena Draco* var. *Boerhaavi*, a fine *Acanthorhiza aculeata*, *Phoenix rupicola*, *Bambusa arundinacea*, *Encephalartos Lehmannii*, *Pritchardia Martiana*, *Marattias*, *alata* and *sorbifolia*, *Howea Forsteriana* of exceptional size, two very large *Phoenix reclinata*, and *Cereus peruvianus* 22 to 26 feet long. *Ch. De Bosschere*.

"THE ROSE GARDEN."—Mr. W. PAUL has published a supplement to his well-known book on this subject. It comprises a list of the new Roses introduced since the last edition was published in 1888. In so doing he has laid special stress on what are now called garden Roses, in contradistinction to those which adorn the exhibition tables. In the one case the object is to obtain what is considered a perfect flower; in the other, the aim is to secure the most pleasing effect of which the Rose-bush itself is capable of yielding. The author takes a middle course in reference to the value of the Manetti stock,

considering it as much underrated as once it was over esteemed. The advance in Tea Roses, and those of the Polyantha section, is recorded, and mention made of the Rugosa section and the hybrid Sweet Briars. The fugacious nature of the latter is alluded to, and furnishes thus a hint which Rose-raisers will do well to note. No fewer than 229 varieties are enumerated in this supplement.

VARIATION OF COLOUR IN A HYACINTH.—

Through the courtesy of Messrs. JAS. CARTER & Co., our attention has been directed to a "sporting" Hyacinth. The variety is Charles Dickens, and its normal colour is deep blue. The plant in question has produced two fine flower-spikes, and the blooms upon one of these are rosy-pink; the other spike, though less altered, exhibits a modification in the blue, the segments of each bloom being very irregularly marked with pink. There has been a complete change of colour therefore in the flowers upon one spike, and a partial change in those on the other. A Hyacinth that would produce several flower-spikes of different colours, would doubtless prove to be valuable. In this case the variation appears to be progressive, and it is likely that another season the whole of the flowers would be pink. We believe that Messrs. CARTER intend to watch the possible vagaries of the bulb in the future.

HORTICULTURAL CLUB.—The usual monthly dinner and *conversazione* was held on Tuesday, the 5th inst., when the chair was occupied by Mr. HARRY J. VEITCH; the Chairman, Sir JOHN LLEWELYN, who hoped to be present, being detained by important business in the House of Commons. A valuable paper was read by Mr. J. A. GAMMIE on the "Cinchona in India," in the culture of which he had been engaged for many years in the Bengal Presidency. He described the various species of Cinchona used, the method of cultivation, and the means adopted through the agency of the Post Office for the distribution of the drug to the various fever-stricken districts. He showed how, through extended cultivation, its price had been reduced so as to bring it within the reach of all. A very interesting discussion, in which many of the members present participated, followed, and a portion of this very interesting paper is published in the present issue.

ROSE SHOW FIXTURES IN 1898.—June 15 (Wednesday), York (three days); 16 (Thursday), Colchester; 23 (Thursday), Bath (N.R.S.); 25 (Saturday), Windsor; 28 (Tuesday), Southampton (two days), Sutton, and Westminster (R.H.S.); 29 (Wednesday), Canterbury, Croydon, and Richmond (Surrey); 30 (Thursday), Eltham, Gloucester, and Norwich; July 2 (Saturday), Crystal Palace (N.R.S.); 5 (Tuesday), Harrow; 6 (Wednesday), Farningham, Hanley (two days), Redhill (Reigate); 8 (Friday), Ulverston; 12 (Tuesday), Wolverhampton (three days); 13 (Wednesday), Newcastle-on-Tyne (three days); 14 (Thursday), Halifax (N.R.S.), Canterbury (Hospital Fund), and Helensburgh; 26 (Tuesday), Tibshelf. The next list of fixtures will appear early in April. In the meantime, Mr. MAWLEY will be glad to receive the dates of any Rose-shows (or other horticultural exhibitions where Roses form a leading feature) for insertion in that list. Mr. MAWLEY's address is: Rosebank, Berkhamsted, Herts.

TASMANIAN APPLES.—The offices of the Orient Steamship Company send us information respecting the movements of their ships as follows:—The *Cuzco* is due here on April 2, with 10,000 boxes of apples; the *Oruba* on the 16th; the *Ormuz* on April 30; the *Austral* on May 14; the *Ophir* on the 30th. These are the time-table dates, which in some cases may be anticipated by a day in the actual arrivals.

NATIONAL AURICULA AND PRIMULA SOCIETY (Southern Section).—The twenty-first annual report of this society, which has as its president Sir JOHN T. D. LLEWELYN, Bart., M.P., and as honorary secretary, Mr. T. E. HENWOOD, Auricula Villa, 16, Hamilton Road, Reading, has been issued. The financial statement discloses a total income for the year 1897 of £87 17s. 3d., with a satisfactory balance

in hand after the payment of all expenses of £16 14s. 9d. The committee report a most successful season, a large increase of membership, and an improved monetary position. A list of the prize-winners, and names of their flowers shown at the Drill Hall, James Street, Westminster, on April 13, 1897, together with the conditions for exhibitors at the forthcoming show on April 26, are appended to the report.

THE GARDENERS' BENEFIT SOCIETY.—We would draw the attention of our readers to the report of the annual meeting on p. 174 of the United Horticultural Provident and Benefit Society. The advantages offered by this society are such as should commend the institution to gardeners generally, but especially to the younger members of the profession.

THE LONDON WHOLESALE FRUIT AND POTATO SALESMEN'S AND GROWER'S BENEVOLENT SOCIETY.—The sixth annual dinner of this society took place on the 15th inst. at the Holborn Restaurant. The Right Hon. the LORD MAYOR in the chair, supported by the Hon. W. F. D. SMITH, M.P., Lieut.-Col. PROBYN, J.P., L.C.C., and Mr. HARRY LAWSON, L.C.C. There was a large attendance of salesmen from the different London markets, and a good many visitors, the company numbering in all over 220. The LORD MAYOR pleaded eloquently for contributions to this deserving charity; and Mr. GEO. COLEMAN, chairman of committee, in responding to the toast of "The Society," asked specially for annual subscribers amongst members of the trade, as there were several candidates who were unsuccessful at the last election. The sum announced as collected at the dinner amounted to £338, which included a contribution of £100 from the Duke of BEDFORD. This is the second donation the society has received from his Grace. There was a good selection of music, and the evening passed off in a very pleasant manner.

PUBLICATIONS RECEIVED.—*Kolozsvár Botanic Garden Catalogue of Seeds*, offered in exchange. Dr. GY DE ISTVANFFI is the director of the garden.

PLANT PORTRAITS.

BOMAREA CARDERI, Mast.—*Revue de l'Horticulture Belge*, March.

CANNA M. VIDAL, segments yellow, with a deep central blotch of red, and spots of the same colour.—*Revue de l'Horticulture Belge*, March 1.

DENDROBIUM SCHRODERIANUM.—*Gardeners' Magazine*, March 5.

DICENTRA FORMOSA.—*Mechans' Monthly*, February.

HIBISCUS MANIHOT.—*Garden*, Feb. 12.

PEAR, RENÉ DUNAN.—*Bulletin d'Arboriculture*, &c., February.

ROSA ALTAICA.—*Garden*, Feb. 26.

ROSA TOMENTOSA WOODSIANA.—*Garden*, Feb. 26.

ROSE CRIMSON RAMBLER.—*Rosenzeitung*, February.

ROSE GILLEMOT (Tea).—*Rosenzeitung*, 1 December.

ORIGIN OF THE GANDAVENSIS GLADIOLUS.

It was the late Mr. Louis van Houtte, the well-known Ghent nurseryman, who gave this name to a hybrid Gladiolus offered for the first time to the trade by him in the year 1841. I have before me Mr. Van Houtte's catalogue No. 6 (autumn, 1841), in which he offers Gladiolus gandavensis as the novelty of the year, at 25 francs (5 dols.) for medium-sized, and at 70 francs (14 dols.) for very strong bulbs. The first coloured plate with elaborate description appeared in the *Flore des Serres*, March, 1846, where the hybrid is stated to have originated from a cross between the Cape species, Gladiolus psittacinus, and G. cardinalis, in the gardens of the Duke of Aremberg, at Ghent.

This Gladiolus gandavensis created a sensation, but was soon surpassed by numbers of seedlings, which have since been offered under fancy names. A complete collection of gandavensis hybrids from 1841 to the present day would embrace many thousands of named varieties, some fifty and more new names being annually added by various raisers. The old varieties, with a few exceptions, are entirely aban-

doned now, and the standard of the whole section is still improving from time to time. The old type of 1841 is still used as a cheap bedding variety, although it is rather poor compared with the majority of other cheap varieties.

The term "gandavensis" nowadays refers to the whole section; but when no varietal name is added, the old type is meant.

More recent sections of late-flowering garden Gladioli have been termed Lemoinei, nanceianus Childsii, &c., which all have their distinct characters relative to their origin. *Ernst H. Krelage*, in "American Gardening."

ALPINE GARDEN.

NEW AND RARE PLANTS FOR ROCKERIES.

(Continued from p. 50.)

Draba repens.—From the alpine regions of the Caucasus comes a charming little plant rarely found in gardens, although another species is often cultivated under the same name, a creeping plant covering the ground with prostrate branches bearing pretty oblong-lanceolate leaves. This *Draba* has, from May to July, numerous conspicuous yellow flowers arranged in small erect spikes. It requires a rocky position and sunshine.

Draba tridentata, also from the Caucasus and the mountains of Armenia, forms pretty and often close tufts spreading over the ground; the leaves, as is rarely the case with *Draba*, are terminated by two or three more or less sharp teeth; the flowers are rather large and of a beautiful yellow, nearly orange-colour. The plant requires sunshine.

Then there is a third species of *Draba*, also of oriental origin, known as *D. scabra*. The seeds of this were brought us from the Circassian Mountains in 1892 by MM. Levier and Sommer. This is the prettiest *Draba*, forming rather spreading tufts over the ground, with deep green foliage, shining needle-like leaves, somewhat suggesting that of Junipers. The flowers are of a beautiful yellow colour, appearing in succession from April to July, and again in the autumn. The plant requires to be grown in a cleft in the rock, and to be exposed to the sunshine.

Epilobium luteum.—I do not know if this curious and beautiful species is cultivated in England. I have nowhere met with it, and its introduction here was due to M. Joseph Vesely, of Vienna. It is a small perennial species with erect stems nearly four inches high, furnished with broad amplexicaul leaves, and bearing numerous and very large straw or canary-coloured flowers; a rare if not unique tint amongst *Epilobiums*. This plant is from the Rocky Mountains; we have grown it since 1887, but have never entirely acclimatised it owing to the cold of our winters—it should be hardy in England. In any case the beauty of the flowers and its rarity entitles it to a place in our rockeries. It requires cool moisture, and not too deep shade; it is easily multiplied by dividing the tufts, or from seed.

New Zealand is rich in *Epilobiums*, and has sent us many species and varieties, the flowers of which are of no particular value with the exception of *E. melanocaulon*, with beautiful and large clear rose corollas and with graceful foliage; *E. linnæoides*, with pretty dentate leaves, really quite ornamental; *E. glabellum*, *Hectori*, *brevipes*, *nummularifolium*, and *pedunculare*, all from New Zealand or Tasmania. They form pretty clumps for rockeries. It is dangerous to introduce *E. pubens*, which is unattractive, and spreads so rapidly as to become a pest difficult to eradicate.

Erigeron compositus, from the Rocky Mountains and clefts in the rocks of Arctic America, is remarkable in that the leaves are cut and divided like those of a *Chrysanthemum alpinum*, or of an *Anthemis*.

Erodium cheilanthesifolium from the rocks forming the summits of the Sierra Nevada at an altitude of between 5,000 and 8,000 feet, a pretty tufted species, with a thick rhizome; leaves deeply cut, greenish; flowers large and white striped with purple, with two black spots on the two superior petals. This plant requires a sunny place on the rockery.

E. daucoides, from the calcareous rocks of the Sierra Nevada, about 6,500 or 7,000 feet in altitude. The plant is remarkable not only for the appearance, but for the perfume also of the leaf, which resembles that of the Carrot. It forms denset tufts of verdure, from which rise the flower-stems bearing graceful umbels of bright carmine flowers. This species flourishes in all soils, but prefers a calcareous and sunny spot. In the garden of the Linnæa, at Bourg St. Pierre (4,600 feet altitude), it sows itself freely; while at Geneva it yields but few seeds, though, it is true, we grow it here in too deep shade, the plant being a sun-lover.

E. Olympicum, is a plant introduced by Boissier about 1840, but rarely seen in gardens though ornamental, forming large tufts of greyish foliage, whence rise in summer and up to the winter, numerous flower-stems. The blossoms are large, rather bright mauve, an unusual colour for an *Erodium*. This species has not seeded with us, nor with M. Barbey at Valeyres, so the only means of propagating it is by cuttings, as with zonal *Pelargoniums*. The

pyrenaica *superba*, introduced in 1884, which has flowers double the size of those of *S. o.*, and a more erect and compact habit, and in colour it is rosy-lilac. The form was described in the *Gardeners' Chronicle*, vol. xxi, new series, p. 419. *S. o. major* is merely a form whose flowers are bigger than the type, but it is not nearly so fine as the preceding. A white form, *S. alba*, is identical in every respect, except in colour; *S. o. splendens* has rosy-purple blossoms, and is the Welsh form of the species. The various species succeed when planted in moist sandy loam, in chinks and on ledges of a rockery; it will also grow well in peat. *E. S.*, *Woking*.

NURSERY NOTES.

MESSRS. W. L. LEWIS & CO.

BRAZILIAN Orchids are a great feature at this Southgate establishment, and *Cattleyas* and *Lælias* are especially fine, plants of *L. purpurata* being very profusely set with flower-sheaths. Among them are

triumphans, and the remnant of the fine strain of *Lælia pumila*, introduced by the firm, which was often shown and greatly admired during the past year.

Varieties of *Dendrobium nobile*, and other *Dendrobies*, made a fine show, and in a warm Orchid-house were noted specimens of *Phalænopsis*, some of *P. Schilleriana* being in bloom. Here, as in some other gardens, the only place in which *Phalænopsis* thrive satisfactorily is this little-warm house, which is entered from another glasshouse, and has no other entrance. Among *Cypripediums* in bloom were remarked *C. Victoria Marie*, *C. exul*, *C. Calypso*, *C. leucorrhodum*, *C. Mastersianum*, and in bud a promising hybrid between *C. bellatulum* and *C. callosum*—probably a variety of *C. × Wottoni*. In another house we noted a fine display of plants of *Odontoglossum crispum*, some of them being in flower; and others were *O. Andersonianum*, *O. Oerstedii*, *O. tripudians*, *O. Hallii*, &c.

A good show of *Odontoglossum Rossii majus*, and others of the smaller-growing species, was observed in another house, and coming into bloom a strong plant of the *Habenaria Bonatea*, a S. African terrestrial species, going generally under the name of *Bonatea speciosa*.

PHALÆNOPSIS × JOHN SEDEN.

THE flower illustrated at fig. 68 was shown by Messrs. Jas. Veitch & Sons at a meeting of the Royal Horticultural Society on the 8th inst. *Phalænopsis × John Seden* was raised from *P. Luddemanniana × P. amabilis*, Bl., and two plants were flowered some years ago (see figure in *Gard. Chron.*, Mar. 17, 1888, p. 332). The plant now in flower, however, was raised from another batch of seed sown in 1891. The sepals and petals are of a blush-white tint, profusely and evenly spotted with crimson; the bases of these segments, and especially of the petals, are of a bright rose hue. The side-lobes of the lip are rose-coloured, spotted with red, and tinged with bronzy-yellow. The middle-lobe of the same is of a yellowish-bronzy hue in the centre, and rose-coloured at the apex—a very handsome-flowered hybrid indeed.

HOME CORRESPONDENCE.

THE WHITE JERUSALEM ARTICHOKE.—Having had some experience with the white variety of Jerusalem Artichoke, I would advise those who may be contemplating its introduction, and destroying the old one, to refrain from so doing. At about the time when tubers were being formed on our plants of the white variety last summer, I noticed here and there a stem which had turned mouldy near the base, and for 1 foot or more upwards; these plants died, and during the remainder of the season others continued to be attacked, although a good many remained apparently healthy. On lifting the tubers some of the attacked plants were destitute of tubers, and others had only a portion of a crop, and there were many diseased tubers, whilst others had a full crop. I stored about 5 bushels of tubers which looked sound, but to-day I have not a dozen sound tubers left, though not any have been consumed. It is a significant fact that of two rows of the old variety grown on the same plot of land none was diseased, and no tuber has been attacked since. The disease, which I have since been told is a form of the fungus known as *Peziza sclerotiorum*, I recognise as being the same thing which invariably attacked a portion of a row of annual Sunflowers that grew year after year on the same spot in another garden a mile away; and I have found it, too, on individual plants here, but as these were few in number, very little notice was taken of it. Now, I am inclined to consider this species of fungus a most dangerous one, that must be got rid of. On the tubers in store it begins to spread as a white mould near the point of detachment from the roots, and soon afterwards the entire tuber becomes a decaying mass. [See *Gardeners' Chronicle*, Sept. 15, 1883, p. 333, fig. 50. Why do you not dress the tubers in store, and also the plants when in growth, with the Bordeaux Mixture? Ed.] J. C. Tallack, *Livermere Park Gardens, Bury St. Edmunds*.

THE ROYAL HORTICULTURAL SOCIETY'S AWARDS.—Whether either of the communications published last week on this subject add much to the

FIG. 68.—PHALÆNOPSIS × J. SEDEN.

plant comes from the rocks of Greece and the East. It likes a sunny place on the rockery.

E. pelargoniflorum comes from the rocks of Mount Ghelipel (Cilicia). It has soft foliage, resembling that of *Erodium hymenoides*, but the leaves are erect; the flowers smaller, and much spotted with purple. It requires a deep cool soil, and a sunny or semi-sunny position. H. Correvon, *Jardin Alpin d'Acclimatation, Geneva*.

SAXIFRAGA OPPOSITIFOLIA.

On the rockery this pretty species and its various forms are now in flower, and although not new plants, they are not so often seen in our gardens as they deserve, if we consider their hardiness, and the simple methods of cultivation demanded. The typical species, *S. oppositifolia*, is British, but one that is rarely found in a wild state, although Dr. Hooker in his *Students' Flora* mentions it as being found in Wales, in the Highlands of Scotland, in the North and North-west of Ireland, as well as throughout Southern Europe. The flowers, solitary, are borne in profusion, on creeping leafy stems, about 6 inches long, and in colour they are deep purple. The several forms are superior to the type in depth of colour and in size. The best are doubtless *S. o.*

two plants derived from the same mass as that which produced the fine *L. purpurata* Lewisii—the nearest to a white form of any of the varieties. A large number of *Lælia tenebrosa* will form a fine display in the summer, and some *L. cinnabarina*, *L. harpophylla*, and good varieties of *Cattleya Trianae*, are now in flower. Among a large number of *Cattleya Mossiae*, about to flower for the first time, are imported plants, reputed white varieties, as well as some white *C. Luddemanniana*, said to be of the *C. L. Schroderiana* and *C. L. alba* type, all of which they prudently determined to retain until the plants bloom. There are also in this house some noble specimens of the true *Oncidium ampliatus majus*, which have large and stout flower-spikes, some of them numbering from twelve to eighteen branches. Plants of *Cattleya Mendeli* were noted to be well furnished with flower-sheaths; and plants of *Oncidium sarcodes*, *O. Marshallianum*, and *O. varicosum*, possessed very large pseudo-bulbs. Among plants in flower there were *Schomburgkia undulata*.

The Mexican-house furnished a display of *Oncidium spilopterum*, whose spikes of yellow and purple flowers make it a handsome cool-house species; some pretty *Odontoglossum Pescatorei*, some large-bulbed *Oncidium concolor*; *Cattleya citrina*, *Odontoglossum*

discussion that is valuable or not, at least they serve to show that the matter has aroused considerable interest. I am personally concerned with that of "Looker-On," and only so far as he makes reference, a very mistaken one, to my recent proposal, that awards of certificates, &c., should be made only by a two-thirds majority of the members present. That is a sensible proposal, because the object is to secure for any award a majority that shall command respect. To assume that an award carried by, say, six votes to four out of a total of twenty members present is proper, is indeed absurd. But there is not a word in my proposal making it compulsory on any or all members to vote. If they do not care to vote, no power can compel them, although refusing to do so is practically admitting indifference or ignorance. All I ask is, that at least two-thirds of the members present shall vote aye before any award of certificate, &c., can be made. If there be at a committee eighteen members present, an average number, at least twelve must vote for, although the other six may not vote at all, or, if they wish, against. In what respect is that an unwise suggestion? The assumption that such a rule would remain a dead letter is based on ignorance of what is required. It is a rule that should be adopted in all cases. It is the rule where three judges have the awarding of prizes of exceeding value, and surely it is not too much to ask that it may be the rule of the committees. *A. D.*

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Seeing so many remarks lately respecting the above institution in the pages of the *Gardeners' Chronicle*, it has occurred to me that there must be a large number of gardeners who do not understand the scope of this Society. 1st. As to its name. It is called the Gardeners' Royal Benevolent Institution, not the Gardeners' Benefit Society; consequently all gardeners who can substantiate their claim to be gardeners are eligible to its benefits (see Rule 2, "Persons eligible"). 2nd. The object of the Institution is to relieve distressed horticulturists, as nurserymen, gardeners, market growers, and seedsmen. 3rd. I believe far more subscribing gardeners are relieved than are paid for by gardeners. There are about 620 gardeners who subscribe £1 ls. annually; there are 571 gardeners who have given £10 10s. and are life subscribers, which brings in at 3 per cent., about £180 per annum, making a total of about £831 per annum. There are about 161 pensioners on the list, and who are regularly receiving their pensions at a cost in pensions only of £2,787; the office or other expenses are included in this amount. 4th. What would become of the distressed gardeners if the above £831 subscriptions from gardeners only were available? It must be borne in mind that even that sum would be greatly reduced by office and other expenses; the whole sum could not be used as pensions. It is consequently necessary to allow those who so generously subscribe so largely to the funds to give their votes to those for whom they may have a fancy. I grant it in some cases brings about what seems to be and is, a hardship. But how can it be prevented without creating a worse evil? As one of the members of the committee, I can say everything that we can do is done, and every case is well looked into, and I believe fairly put in the list of applications, so that no one has a bias or preference as from the committee. The only real and permanently effectual cure for an admitted evil is for all gardeners to become members, then they could always vote in all those who have been subscribers. *Wm. Denning.*

ROYAL GEORGE APPLE.—On p. 129 of the *Gardeners' Chronicle*, Mr. N. H. Pownall's high opinion of this Apple verifies its good late properties and beauty, and agrees with my own in regard to it. It is interesting to learn the name of the place of its origin. It would help gardeners before cancelling the old name and adopting a new one, if Mr. Pownall could ascertain the year of its first coming into commerce, and if it was at that time known as Clarke's Seedling. In the *Gardeners' Chronicle* the week following, Mr. Goodacre's remarks had some instructive notes on the variety. In seasons of scarcity, I have, in April, paid 5s. per peck for apples sold under this name by growers living near Nottingham, which came wrapped in paper, and I was told that the fruit was stored in that manner. I have seedlings raised from this variety. It is a difficult matter to get a correct list of Apples raised early in the present century, with descriptions and date of introduction. None is more trustworthy than Thomas Knight's and McIntosh's, and the last-named cultivator verified many of the names of fruits from

the London Horticultural Society's lists before publishing his information. I will quote from the most modern of these lists, published 1828, in Mr. McIntosh's *Practical and Modern Horticultural List*, vol. i., where 250 varieties of Apples are described, on p. 459. No. 114 of this List is Royal George; Clarke's Seedling is, however, not mentioned. In another very trustworthy work, embellished with beautiful drawings of subjects from nature, viz., *Flora and Pomona*, by Chas. McIntosh, C.M., C.H.S., the plate of Kirk's Scarlet Admirable shows a fruit that exactly resembles Gascoyne's Scarlet Seedling, and the name is doubtless merely a synonym. Another valid reason for raisers to carefully tabulate the parents of the fruit they raise. I thank Mr. Goodacre for putting me right in the matter of the name Newton Wonder, for I was incorrectly informed that Mr. W. Taylor, of King's Newton, Derbyshire, was the raiser. King's Newton and Stanton are neighbouring parishes. *George Bolas, Hopton Hall, Wirksworth, Derbyshire.*

THE CROCUS IN THE SPRING GARDEN.—It is worthy of note that the yellow spring Crocus (*C. aureus*) appears to be much more lasting than the white, violet, and striped varieties of *C. vernus*. The flowers of the former appear to be shorter in the corolla, and the petals stouter in texture, than those of the forms of *C. vernus*. They come into bloom first, and they last beyond the time when the others are fading. Moreover, the blossoms are less affected by rain. I have examined a large bed of Crocuses to find that immediately following a sharp storm of sleet and wind, the flowers of the white, striped, and blue varieties were much more damaged than those of the yellow. The yellows, three days after, are brilliant in their golden tint. Alas! the others went down before the storm like nine-pins, never to rise again. Then I think it will always be found that for permanent plantations the yellow is much more to be depended upon. I made a permanent plantation twenty years ago; the yellows remain, and appear to flourish as freely as ever. I am giving my own experience, and if it is general, it points to the fact that *C. aureus* is most to be depended upon for permanent edgings. And let me add, the original planting should always be done in the best manner to ensure this continuity. *R. D.*

THE COLOUR OF DAFFODILS IN RELATION TO THE SOIL.—We are familiar with the effects of different soils and chemicals on the colour of the flowers of *Hydrangea hortensis*. Through the insertion of iron nails, iron-rust, steel-filings, common alum, green vitriol, into the pots or root-runs of *Hydrangea*, the colours of the flowers are more or less changed from purple to blue. It was never, however, made very obvious why solutions of common alum favoured the change to blue more than sulphates or salts of iron. At the last meeting of the Botanical Society in Edinburgh, Dr. Aitken read an interesting paper on the colour of flowers as affected by the character of the soil in which they grow. After referring to the generally known facts in relation to the *Hydrangea*, Dr. Aitken quoted Mr. Barr, the greatest of our Daffodil growers, as testifying to having noticed that Daffodils possessed a much deeper tint when grown on some soils than when grown on others. It has also been noticed by other cultivators that on some peats *Hydrangeas* come blue without either alum or salts of iron, and that Daffodils and other bulbs are considerably modified in colour. Mr. Barr had sent three samples of soil to Dr. Aitken, who analysed them, and exhibited the results of his analysis. The palest Daffodils, having a sulphur-yellow colour, were grown on the poorest soil, and the deepest-coloured were grown on the richest of the three soils, but it did not appear that the differences of colour were due to the abundance or otherwise of any one constituent of the soil. At the same meeting, at which Dr. Semple presided, a communication, with lantern illustrations, was read by Mr. R. Turnbull on *Apodya lactea*, one of the *Saprolegniaceae*. *D. T. F.*

OTHER LITTLE GARDENS.—Mr. Harry Roberts, the writer of the interesting "Little Cornish Garden" articles, says that "plants in pots savour too much of the pet-bird idea." But there is one charm in pot plants which is not possessed by the planted-out plants. They can be brought into the house, and enjoyed while resting from the labours of the garden, which means a great deal; moreover, in rainy and cold weather, when one would be glad of a comfortable seat near the fire, pot plants will greatly help to keep him or her in company. Then he says he has planted Crocuses and Primulas, but he might

have added how he defends these beautiful things against the attacks of birds. He says, "Primulas are among the easiest plants to grow;" so I also had thought, and therefore I planted some 150 clumps, thinking I would make a lovely edging to some borders of Primulas and Polanthuses. Many of them were in flower when planted, and so I arranged them so that their flowers might make a pretty contrast. Well, the beautiful contrast was exhibited next morning, for every flower and every flower-bud without exception, was lying on the ground round each plant, just as dead soldiers lie on the ground the morning after a great battle! The suspicion of this havoc fell on sparrows, which I see chasing each other in the morning from my upper window. The curious thing was that they did not eat them, but picked them off and threw them about as if it were from mere mischief. Now can Mr. Harry Roberts suggest some remedy for all this trouble, so that my 'little garden' may not be a blank, as regards these pretty things; otherwise I would have to lift them again, and plant them in pots, which he says "savour too much of the pet-bird idea." I have often seen beds of Primulas in Hyde Park, but I never witnessed such wholesale havoc before. When I was in India, I had *Amaryllises* in flower in my verandah; I had also a peacock in the compound. One fine morning I found all my beautiful *Amaryllis* flowers wrecked by this mischievous peacock, so I bundled him away, and presented him to a friend who lived at some distance from my domain. I wish I could send away the sparrows, or whatever birds wreck my Primula flowers. Then, with regard to Crocuses, there are some interesting phenomena to be recorded. A few spontaneously came up, evidently planted by some former occupant. Some were yellow. These were immediately wrecked by the birds, while the white and purple ones did not seem to be touched. I am told that every one knows that birds destroy yellow Crocuses, yet the other day in St. James' Park I saw large patches of yellow, white, and purple Crocuses, and the yellow ones did not seem to be touched. Moreover, not far from my place I saw in a small garden, hundreds of beautiful yellow Crocuses, and only yellow ones, yet not one seemed to be touched. Can any one explain these vagaries of birds, and suggest some remedy against their mischief? *E. Bonavia, M.D., Worthing, March 14, 1898.*

THE STRAWBERRY PLANTED IN BARRELS.—A few years ago my neighbour who grows a few Strawberry-plants, observed a paragraph in a newspaper advising the cultivation of the plant in barrels, and an Apple-barrel was obtained, holes bored in the sides, and plants of King of the Earlies planted in the holes and on the top. They did well and fruited freely, but as water was scarce they sometimes suffered in consequence, and the method was eventually given up. Grown in this manner, a good deal of water is required, but where a plentiful supply is at command this would be no obstacle. *S. Arnott, Carsethorn, by Dumfries, N. B.*

GARDENIAS.—In answer to your correspondent "J. E.'s" appeal for information regarding the cultivation of *Gardenia floribunda*, radicans, &c., allow me to relate my methods, which if "J. E." would follow he would have little disease or canker of which to complain. I do not keep my plants longer than four years; they are pruned hard towards the last days of May, and then placed in a house having a temperature of 65° to 70° for one month, and then removed to a deep greenhouse-pit where plenty of air and full sunshine are afforded, manure-water being applied occasionally, and syringing done at shutting-up time at 12.30 P.M. The plants remain in this pit till the end of September, when removal to a house with a temperature of 55° to 65° takes place, and here they remain till in the New Year they are removed to a house with a temperature of 65° to 75°, in order to set their flower-buds, and to flower where growth is commenced. I have had a plant grown in good fibry loam and silver-sand in a 10-inch pot with 100 good blooms upon it. *W. Willatts, Lyndhurst.*

—With reference to the inquiries of your correspondent, "J. E.," whose letter is printed on p. 157, I can only suggest that the disease referred to is due to some local influence, as such cases are very rare indeed, and I do not know of a similar case. My advice would be not to re-plant the Pine-stove without thoroughly disinfecting with fumes of burning sulphur, all cracks and holes having been previously stopped, and care taken to place the vessel containing the sulphur

at the lowest part of the house. To make the sulphur fumes everywhere accessible, the bottom slabs of the hot-bed should be removed. If the sulphuring be performed in the afternoon, the house should remain closely shut up till the next morning. To prevent the discoloration of painted woodwork, this should be lime-washed, if practicable, prior to which a good washing with a garden-engine or the hose would not be amiss. Too frequently Gardenias are afforded too much warmth, insufficiently ventilated, and too densely shaded, or the shading maintained for too long a period. The plants previously referred to are shaded slightly with a permanent shade of lime-wash, put on in primitive fashion by means of a syringe. Gardenias need no bottom-heat, and no peat, but sandy top-spit pasture loam, six or eight months cut, and stacked with layers of stable-dung between. This should be employed in the

should be afforded. Indeed, and in this semi-stationary way, market men keep their plants through the winter. J.

HARDY PLANTS FOR FURNISHING FLOWERS FOR CUTTING.—I would ask Mr. W. H. Ward if he does not err in recommending (see p. 156, ante), without any qualification, *Alstroemeria peregrina* alba, and tricolor (pulchra) as being suited for planting in the open ground for furnishing flowers for market? These varieties are none of them generally quite hardy in this country, and are on that account unsuited for out-of-doors cultivation excepting in the warmest districts. Will Mr. Ward be so good as to give me one instance in England where the lovely *A. peregrina* alba is grown to perfection in the open air, and in quantity for market purposes? Indeed, of the whole of the species mentioned by

of soil interposed. Planted in early autumn, *Alstroemerias* are the better for being planted in beds by themselves, if the only object is cut bloom, so that they may be left for ten or a dozen years undisturbed, provided a good mulch is afforded every year after three years planted. The spring is the worst time Mr. Ward could select for planting these subjects, because even if dry roots are available, which is doubtful, these will be too greatly shrivelled to do any good this year; while if he would trans-plant from an old bed he will find, to his cost, the brittle nature of the *Alstroemeria* renders their extraction very difficult. Mr. Ward mentions in his article the English and Spanish Iris, Double Daffodils, but surely he does not include these things as among suitable subjects for planting in March [he does not say that. Ed.]. Daffodils are in flower nearly everywhere, and the Iris named have been, in many instances, above ground for two months past. Another unsafe plant, out of doors, mentioned by Mr. Ward is *Francoa ramosa*, a half-hardy subject not suited to open air market culture. I quite agree there are plenty of good perennials suited for spring-planting, but many of these are unnoticed in Mr. Ward's rather mixed list. In a subsequent note I will give the names of some of these plants with your permission. E. Jenkins, Hampton Hill.

CYCLAMEN DEVELOPMENT.

We give this week a figure of the most remarkable variety exhibited by M. L. P. de Langhe, of Brussels, at the last meeting of the Royal Horticultural Society. As will be seen, the flower is very large, flat, like an open umbrella, and slightly fringed at the edges. The colour was rosy-crimson. It is the most remarkable variety we have yet seen, and is not the result of cross-breeding between species, but simply a variation from *C. latifolium*.

SOCIETIES.

ROYAL HORTICULTURAL. Scientific Committee.

MARCH 8.—Present: Dr. M. T. Masters (in the chair); Rev. W. Wilks, Mr. A. Sutton, and Rev. Prof. Henslow, Hon. Sec.

Phytoptus ribis.—An interesting letter was received from Miss Ormerod giving an account of what is being done experimentally at the Duke of Bedford's fruit farm at Woburn, under the direction of Mr. Spencer Pickering, F.R.S., as to the possibility of obtaining "mite-proof" Black Currants, the only result has been some plants received from Buda-Pest, which have been distributed to the Toddington fruit grounds, to Mr. Speir Newton's farm, Glasgow, and to Woburn. Miss Ormerod has given as exhaustive an account as she could form of the disease in a special appendix to her twenty-first annual report from the period of its first appearance until the present time. A series of experiments is now being set on foot at Woburn directed to every point which is open for serviceable action, including chemical applications. These will be followed by expert examinations of the contents of the galled buds treated; and with coincident examination of galled buds under precisely similar circumstances, but not treated chemically. These experiments will be found detailed in the appendix, pp. 141-158. A conclusion anticipated is that there should be "a difference in broad scale methods of growing."

Scotch Fir, Malformation.—Mr. Veitch sent a curious mass of stunted boughs, the whole resembling a hedgehog, and perhaps caused originally by a phytoptus or fungus. Dr. Masters observed that short boughs, grafted from such specimens, might be used as miniature trees, for rockwork, &c.

Sprouting Broccoli.—A remarkable specimen was received from Mr. W. P. Wright, Willesborough, Ashford, Kent, from the central and much enlarged stem of which a large number of good sized lateral shoots had appeared. It was suggested that if it be capable of being "fixed" it would probably prove a valuable acquisition.

Phytoptus on Hazel.—Mr. G. Gordon sent specimens of this well known gall, allied to the Currant-mite. The samples were received from Kent, where the Black Currant is badly infested. It was first observed at the locality on the Hazel last year. [Known in Kent from time immemorial. Ed.]

Orchid Roots with Fungus.—With reference to the specimen brought to the last meeting, Mr. Murray, of the gardens, Oakwood, Wylam-on-Tyne, writes to say that he is "convinced that it is from no other cause than from the lack of air, or, rather, of circulation of air, among the plants." In a previous communication to Mr. Douglas, he expressed agreement with Mr. Veitch's interpretation, but not quite in the manner he explained, for he observes, "I ventilate the houses day and night with the ventilators, . . . but the air upon the stages, or, rather, above the stages, when the plants are standing close together, travels very slowly, even with the ventilators open, in comparison with that around the centre staging, as plants thereon seldom show signs of fungus."

FIG. 69.—A VARIETY OF CYCLAMEN LATIFOLIUM (PERSICUM),
SHOWN BY M. DE LANGHE.

rough state, as chopped from the stack. Small plants should be planted on mounds after the style as described in my previous communication. In planting do not bury the collar of the plant beneath the soil; and select plants that possess a clear stem of 6 inches high. A temperature of 60° to 65° is much better for the plants than one that is stuffy and 10° higher than these figures. Free ventilation is essential in the summer-time, and the house may be kept 5° warmer for a time after the pruning is finished, that is, as soon as the glut of flowers is over. At this time syringe the plants with the following mixture:—Two handfuls of fresh soot and one of flowers-of-sulphur, mixed together while dry, after which mix in a paste and then incorporate with water gradually and stirring meanwhile; then dissolve six ounces of soft soap in four gallons of soft water, and pour the two mixtures together, and strain through fine muslin. When growth is complete, a rather low temperature and drier atmosphere

Mr. Ward only two possess any real worth for market-growers, and these are *A. aurea* and *A. psittacina*, the remaining six species and varieties being either unsuitable in point of colour, such, for example, as the typical *A. peregrina*, with purple flowers, or are they too distinctly tender for ordinary open-air culture at all? Indeed, the whole family, including the reputedly hardy ones, require to be planted fully 6 inches below ground to render the roots secure against frost; and near London I have known hundreds of tubers planted 5 inches deep to be killed in a warm sunny spot in the open in well-drained soil. The best and most profitable of all is *A. aurea*, or *aurantiaca*, as it is sometimes named in nursery lists, which is not only the hardiest and most vigorous, but an abundant bloomer, and one that increases best. I always prefer to plant the roots of this species 8 inches deep, after digging the ground 1½ foot deep, putting a layer of well-decayed cow-manure 4 inches below them, with that thickness

Two and Three-Spathed Arums.—Mrs. Richards of Westridge, near Ryde, forwarded two flowers, one with two spathes, the other with three, both from the same plant. They were very fine instances, and it was reasonable to expect such might prove constant. If so, a permanent form with two or more spathes would be very desirable.

Azaleo-dendron X.—A hybrid between an *Azalea mollis* or *sinensis* and a spotted *Rhododendron*, exhibited by Sir Trevor Lawrence, was unanimously awarded a botanical certificate. It was raised by Prof. Pynaert of Ghent.

Large Ivy Stem.—Prof. Henslow exhibited a section of Ivy some 10 by 8 inches across. It grew round a tall Holly, about 50 feet in height, at Zeals Rectory, Wilts.

Twin Apple.—A remarkable monstrosity was sent from Mr. Bar-at-Gin, 3, Praed Street. Instead of being the result of the fusion of two flowers, as occurs in Tomatoes, &c., i.e., a "synanthme" condition, a vertical section revealed the fact that they were the result of a bifurcation of the axis below, the under side of the Apple giving no signs of its being a twin.

Cypress Diseased.—A specimen received from Dr. Church, having the bark split and infested with fungi, was forwarded to Kew for further examination. The following report was received: "*Cupressus dolabrata*.—This a typical example of bark-scorching, the cortex being first killed by exposure to the sun's rays, afterwards splits and forms sun cracks, and finally separates from the wood. The fungus present—*Corticium lacteum*, Fries—is simply saprophytic on the dead parts."

THE SHERBORNE AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

This society, which has been in existence for about four years, has 100 members, one half of whom are working gardeners. Certificates are awarded at the monthly meetings to exhibits of excellence. At these meetings papers are read dealing in some way or other with horticulture. At a recent gathering a practical address was delivered by Mr. CROOK, Forde Abbey Gardens, Chard, on "Forced Vegetables," which was followed by a useful discussion.

NATIONAL CARNATION & PICOTEE. Southern Section.

We glean from the twenty-first annual report of this society that considerable progress has been made, thanks to the generosity and untiring energy of the president, MARTIN B. SMITH, Esq., "who not only supplies the members with seeds saved from his best flowers, but also takes an important and active part in the management of the society." Last year's exhibition in the gardens of the Royal Botanic Society was not so successful as had been anticipated, the quality of the blooms being below the average, on account of the unpropitious weather prevailing, and the attendance of visitors was scanty. Special attention is called to the classes for undressed flowers, shown with a sprig of foliage only, and without cards; and to the special prizes provided by the president. The statement of accounts shows total receipts for 1897, including a balance in hand from 1896 of £233 1s. 3d., to have been £493 14s. 9d., and the expenditure £493 14s. 9d., inclusive of the sum of £208 16s. 9d. carried forward to 1898. In addition to the financial statement, the names of the winners of last year's prizes, with those of the varieties shown, a list of subscribers, and a schedule for the present year, are given. The honorary secretary and treasurer is Mr. T. E. Henwood, Auricula Villa, 16, Hamilton Road, Reading.

LINNEAN.

MARCH 3.—Dr. ST. GEORGE MIVART, F.R.S., Vice-President, in the chair. Mr. THOMAS CHRISTY, F.L.S., exhibited specimens of the Mora Nut of British Guiana (*Dimorphandra Mora*, Schomb.), of which some had been lately introduced into London by colonial brokers as the Kola Nut (*Cola acuminata*). It appeared, however, on analysis that the former contains no Caffeine, a product for which the latter is of definite commercial value. It remained to be ascertained whether the Mora Nut has any economic value.

Mr. G. CLARIDGE DRUCE, F.L.S., read a paper on the occurrence of *Carex helvola*, Blytt, in Britain, in which he gave an account of his discovery of this plant on Ben Lawers, Perthshire, in August, 1897. He found it growing in some abundance at an elevation of about 3200 feet. Prof. Blytt and Dr. Christy, to whom specimens had been submitted by agreed in naming it *C. helvola*, which by many botanists is considered to be a hybrid. Professor Blytt says that it grows with *C. canescens* and *approximata* (*lagopina*), but he has never found ripe fruit. Dr. Christy says: "Il me semble d'être une ancienne hybride fixe et plus ou moins stable." Mr. Druce could readily believe that *C. helvola* was a hybrid of which *C. canescens* was one parent, but he had more difficulty in stating definitely the name of the other. From the close resemblance borne by *C. helvola* to *C. Zahni* (an acknowledged hybrid of *C. canescens*, in one of its forms, with *C. approximata*), this combination might well be the origin of the Ben Lawers plant, but against that was the fact that the presence of *C. approximata* in the Breadalbanes had never been proved. *C. echinata*, on the contrary, was plentiful there, but Mr. Druce could see no positive evidence

of the occurrence of that species in the foliage or inflorescence. He would have expected the offspring of two plants with nerved perigynia to have exhibited that character even in young specimens; as is shown in *C. pseudo-helvola*, an acknowledged hybrid of *C. canescens* and *norvegica*. The foliage too was slightly glaucous, a character not possessed by *C. echinata*. Although the Ben Lawers plant was less luxuriant than Blytt's Norwegian specimens, Mr. Druce was unable to separate it specifically from that plant.

Messrs. F. N. Williams and W. P. Hiern offered some remarks.

THE KINGSTON AND SURBITON CHRYSANTHEMUM.

MARCH 7.—A meeting of the committee was held on the above date, and the position of the society was gone into thoroughly. The whole of the liabilities have been discharged, with the exception of what is due to the collector and assistant-secretary (Mr. W. D. Elsam), who voluntarily offered to let that stand over. It was satisfactory to find that last year's subscriptions exceeded in amount the sum received in 1896, and had the takings at the door come up to the average, with a small reduction *pro rata* from the prize money (which is provided for in the rules, and is often done at other shows), the accounts would have stood differently. As it is, the committee are determined to make an effort to wipe off the debt due to the collector, and are encouraged therein by the knowledge that the society has passed through critical periods more than once in its existence of twenty-one years. It has now been definitely fixed to hold the show on November 1 and 2, and Major Ficklin has again kindly allowed the use of the drill-hall for the purpose.

NEWCASTLE AND DISTRICT HORTICULTURAL IMPROVEMENT.

MARCH 8.—A meeting of this Society was held on the above date. There was an excellent attendance, over which Mr. JNO. BULLOCK presided.

The Certificate offered for the best six Camellias was won by Mr. O. BROWN, Oakfield, Gosforth, and special Certificates were awarded to Mr. A. MONRO, Enfield, Gateshead, for *Dendrobium Wardianum*, and to Mr. W. M. HAYES, Ferndene, Gateshead, for *Rhododendron argenteum*.

A paper was read by Mr. HAYES on the Grape-vine, and was followed by considerable discussion, particularly in regard to outdoor cultivation.

SCOTTISH HORTICULTURAL ASSOCIATION.

MARCH 9.—The "majority" supper of the Scottish Horticultural Association was held on the evening of the above date in the Windsor Hotel, Edinburgh. There was a large company. Mr. M. Todd, president, was chairman. After supper the toasts of "The Queen," "The Prince and Princess of Wales, and other Members of the Royal Family," were given from the chair, and the "Navy, Army, and Reserve," by Mr. R. Laird. Mr. MacKenzie proposed the "Lord Provost and Magistrates," and said it had been the good fortune of Edinburgh for many generations to be ruled by a body of intelligent, patriotic, and far-seeing men. He could look back to 1851, and he was simply astonished at the progress that had been made in various directions. Bailie Hay in reply, said Edinburgh owed much to her sanitation and to all that went to beautify her. They had done much to cultivate a taste for flowers, and the taste was growing. They were a large educator, they were a large educational school. It was a very great pleasure to those who were in the Corporation to know that their services, their arduous duties, were appreciated. Bailie Hay, subsequently, in proposing the toast of the evening, "The Scottish Horticultural Association," said that Association twenty-one years ago began in a very small way. They had their meetings first in the Bible Society's rooms, and there they read and discussed matters bearing upon horticulture. They had been banded together for the promotion of the noble art of horticulture, and they had now reached their majority. It was all the more gratifying to know that notwithstanding those many years in the past, they had not lost their vigour, but were fresh, and strong and healthy.

The CHAIRMAN, in reply, said they had done what they could to deserve success, and the public had backed up their efforts, and ample success had followed. They had had no ebb-tide, and their success had gone on year after year. They were very grateful for the encouragement they had received from the Corporation of Edinburgh. Since the Chrysanthemum Shows were established he did not need to say that they had gone on with unvarying success. One success had led up to another. The public had come to look upon their show as one of the most attractive entertainments of the year in their city. He referred to the fact that from their abundance they had very wisely, and he hoped he might claim very generously, devoted part to works of charity. Mr. D. P. Laird proposed "Gardeners and Gardening," and Mr. Dunn, in responding, suggested that for new articles of real merit produced by gardeners the Association should give Medals when a given number of Certificates had been obtained. During the evening the

Chairman, in his name and the name of the past presidents, presented the Association with an album containing a photograph of all the presidents. An enjoyable programme of songs was also rendered. "*Scotsman*," March 10, 1898.

EXETER AND DISTRICT GARDENERS'.

MARCH 9.—The paper read at the last meeting of this Society was one written by Mr. J. W. MOORMAN, Superintendent of Victoria Park, E., entitled, "Variety in the Flower Garden."

Mr. Moorman's experience in the management of public gardens, and his knowledge of the climate of Devonshire, gained whilst he worked at Poltimore, near Exeter, enabled him to emphasise the advice that he gave on this subject. The flower garden, said the writer, need not necessarily be but a mere flash of summer beauty, and by connecting the seasons, anticipating summer and lengthening the autumn season, it is an easy matter to confine the flowerless season to a few winter months. He then gave the names of a number of plants, which, if planted freely, would fill up the remainder of the season, commencing with Winter Aconite and Snowdrops, and concluding with Michaelmas Daisies. Many flowering plants, said Mr. Moorman, were being overlooked owing to the continued introduction of new species and varieties. Among the somewhat neglected ones was the old Monthly Rose. A long list of plants of a highly decorative nature was then given, in order to show how wide was the gardener's choice.

Mr. A. HOPE (Hon. Sec.) presided, and a hearty vote of thanks was passed to Mr. Moorman for his admirable paper.

Mr. T. H. SLADE, Poltimore Gardens, exhibited a number of very fine blooms of seedling *Amaryllis* of Veitch's strain of hybrids; the colours were bright and varied, the form and substance all that could be desired, and several measured 9 to 10 inches in diameter, the flowers bearing evidence of good cultivation.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

MARCH 13.—The annual general meeting of the members of this excellent institution was held on Monday evening last at the Caledonian Hotel, Adelphi, Mr. GEO. WYTHES presiding.

The annual report was read as follows:—"In presenting the annual report and balance-sheet for the year ending January 10, 1898, the committee have great pleasure in stating that the Society continues in a prosperous condition. Sixty-eight members joined during the year, twenty-one lapsed, and three died, one being a lapsed member, and the amounts standing to their credit in the ledger had been paid to their nominees. The membership is now 680. The amount of subscriptions paid by members to the Benefit Fund, including arrears for 1896, was £1,064 14s. 2d. The amount paid to sick members was £232 9s., there having been forty-six members on the Fund. The amount of subscriptions to the Benevolent Fund from honorary and benefit members was £129 1s., and £23 10s. has been granted in small amounts to four members from this fund. The Convalescent Fund is progressing favourably. It is suggested that this fund should now be incorporated in the rules. The amount received for this fund, including donations at the annual dinner, was £28 0s. 8d. Two members received £1 10s. each from this fund. The Management Fund shows a balance of £77 15s. 7d., having benefited to the extent of £10 10s. by donations at the annual dinner; also £10 6s. 6d. by advertisements in the Annual Report. The annual dinner was again held at the Holborn Restaurant. H. B. MAY, Esq., occupied the chair, and fulfilled his office in the best manner possible, and everyone present thoroughly enjoyed the evening's entertainment. The accounts were audited by Messrs. W. Gunner and Geo. Dixon, and found correct. The Committee again invite members of the craft to join this Society, and so lay by something for a rainy day, taking for their motto "Union is Strength."

A detailed account of the receipts and expenditure in connection with the various funds was next read by the Secretary, followed by a most satisfactory statement of liabilities and assets, by Mr. J. HUDSON, the hon. treasurer. We are unable to reproduce them here, but it was decided to print 2500 copies of the Society's report and balance-sheet for distribution, and one of these may be obtained on application to the Secretary, 9, Martindale Road, Balham, S.W.

The CHAIRMAN, in moving the adoption of the report, referred in appreciative terms to the efficient and economical manner in which the management of the Society had been conducted. It had an invested capital which at par value was worth £13,100, and which has recently been valued as actually worth £14,742 10s. There were now on the books of the Society 720 paying benefit members, and thus the capital would average nearly £20 10s. per member. The working expenses had been only about 6 per cent. of the income. The investments during 1897 had been £1200. In 1894 only £301 17s. 6d. was invested in the year, and since then the capital has been increased by £10,000. Members have still been allowed interest at 3 per cent upon the balances standing to their account, which in his (the Chairman's) opinion was marvellous. In conclusion, the Chairman noted with pleasure the exceedingly low death-rate amongst the members.

Mr. W. MARSHALL seconded, and as one of the original members he congratulated the Society upon the prosperity it had acquired. In its first days, when he advanced £10 to the Secretary, to enable the few members to "unite," he was convinced that there was a useful future before it.

The report was passed with unanimity. Next took place the election of officers. There were four retiring members from the committee, but these and the rest of the officers were re-elected, and votes of thanks passed. On the motion of Mr. HUDSON it was decided to pay the secretary for the past year according to rule, and to present him in addition a bonus of £5.

In replying to a vote of thanks offered to the committee, Mr. COLES took occasion to say that next year he hoped to attain the age of seventy, and there would be a sum of about £30 that he would draw. The interest on his deposit fund at the present time more than paid his annual subscription.

The termination of the annual meeting was immediately followed by a special general meeting called for the revision of certain rules.

Mr. HUDSON proposed that in Rule 8 an alteration be made on p. 9, line 8 from the top, "instead of £20, read £30." This was seconded and carried unanimously. The result is that the secretary's salary will henceforth be £30 instead of £20 per year, with the usual *fid.* per member on all those above 300.

Mr. BURGE proposed, and Mr. COLES seconded, an alteration in Rule 14, "that on p. 11, line 10 from the bottom, after the words 'lower scale,' be added the words 'with the privilege of increasing this to,'" carried *nem. con.*

Mr. W. R. THOMPSON proposed, and Mr. WINTER seconded, that in Rule 14, p. 12, line 14 from the top, the word "successive" after "twenty-six" be struck out. The object of this alteration was to prevent a member from obtaining more than twenty-six weeks full sick pay in twelve months, to date from the commencement of the receipt of relief. There was some opposition to this amendment, especially from Mr. TAYLOR, but in the end it was carried.

The following new rule *re* Convalescent Fund was next proposed, and adopted *nem. con.*

VOLUNTARY CONVALESCENT FUND.—"The object of this fund is to give members a change of air during convalescence. The Committee of Management to have power to relieve members of this Society from this Voluntary Fund as they may deem advisable. All cases must be recommended by a duly qualified medical practitioner."

The meeting afterwards separated.

HEALING AND DISTRICT GARDENERS'.

MARCH 15.—The members of this Society have on several occasions shown their interest in the Royal Gardeners' Orphan Fund by carrying out entertainments for its benefit, and thus acquiring substantial sums. On Tuesday last the gardeners, with the consent of their employers, held a charming spring exhibition in the Victoria Hall, and helped by some of the local florists, made a display of a very attractive character, all the more gratifying because there was no prize money to be obtained. The exhibition consisted of groups of foliaged and flowering-plants, spring-blooming subjects greatly predominating, which were arranged down the centre and along the sides of the hall, and on a spacious table at one end, the platform being also charmingly decorated. There were so many contributions that it would be invidious to particularise; suffice it to say, that all who could, contributed to make one of the best displays ever seen in Ealing at this season of the year. The Exhibition was opened by Lady NELSON, supported by Mr. J. Harris, the President of the Gardeners' Society; Mr. William Marshall, the Chairman of the Committee of the Fund; Mr. A. F. Barron, the Hon. Secretary, and others. The weather was delightful, and it is hoped a goodly sum will result from the appeals on behalf of the Fund made by Lady Nelson and Mr. Marshall.

Obituary.

MR. T. KIRK.—We regret to learn from the columns of the *Times* of the death of this eminent New Zealand botanist. Mr. Kirk has been for many years a correspondent of this journal, and did much by his papers and monographs to complete the *Flora of New Zealand* commenced by Sir Joseph Hooker. The work by which he is best known is his *Forest Flora of New Zealand*, in which all the trees and shrubs of those islands are figured and described. The exploitation of the timber is also treated of, so that the work forms a complete treatise on the forestry of New Zealand. Mr. Kirk was for some years conservator of the State Forests of New Zealand.

ROYAL HORTICULTURAL AND BOTANICAL SOCIETY OF GHENT.—At the last meeting of this Society at the Casino at Ghent, M. A. MAERTENS BRACQ in the chair, the following subjects obtained recognition, viz, *Didymospermum porphyrocarpum*, *Phoenix bistris*, and *Anthurium Rothschildianum* *Excelsior* (unanimously), shown by M. L. de Smet, *Certificates of Merit*; *Azalea Madame Louise Cuvelier*, shown by MM. Haerens Frères; *Vriesia Rex*, shown by M. L. Poelman-Maenboud; *Cymbidium grandiflorum* var. *punctatum*, shown by MM. Versypt Frères et Soeurs; *Aechmea pulchella*, shown by MM. Duriez Frères; and *Selaginella Emmelliana aurea*, shown by M. Szewezik, were also awarded *Certificates of Merit*.

ENQUIRY.

"He that questioneth much shall learn much."—BACON.

ASPARAGUS LARICINUS.—Will any of our readers kindly inform "K. W. John" whence he can obtain some seeds of *Asparagus laricinus*.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named: and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

THE following summary record of the weather throughout the British Islands for the week ending March 12, is furnished from the Meteorological Office:—

"The weather during this period was fair as a whole, but falls of rain or sleet were experienced in the west and north at the beginning of the week, and rain had set in again in the north and north-west towards the end of the period.

"The temperature was above the mean in 'Scotland, N. and E.' and just equal to it in 'Scotland, W.' and 'Ireland, N.'; in all other districts it was below the normal, the deficit being 4° in 'England, E.' and 5° in the 'Midland Counties,' and 'England, S.W.' The highest of the maxima were recorded towards the end of the week, and ranged from 57° in 'Scotland, E.' and 56° in 'England, N.E.' to 50° in 'England, E.' and S.' The lowest of the minima were recorded during the earlier half of the week, and ranged from 9° in 'Scotland, E.' (at Braemar on the 8th), and from 16° in 'Scotland, N.' to 26° in 'England, S.' and to 32° in the 'Channel Islands.'

"The rainfall was less than the mean in all districts, and in all but the extreme northern and south-western districts the fall was very slight.

"The bright sunshine again exceeded the normal amount in most districts, but was rather deficient in 'Scotland, W.' eastern, central, and southern England, and the 'Channel Islands.' The percentage of the possible duration ranged from 43 in 'England, S.W.' 41 in 'Scotland, E.' and 40 in 'England, N.E.' and N.W.' to 22 in 'England, S.' and 20 in the 'Midland Counties.'"

THE FLORA OF ARID REGIONS.—M. L. G. SEURAT has published, in the February issue of the *Revue Générale de Botanique*, some interesting facts relating to the plants of the arid districts of Mexico, and the manner in which these are peculiarly adapted to enable them to withstand the adverse influence of the dryness of the soil. These adaptations are especially pronounced in species which prove themselves capable of living on the ancient slopes of basaltic lava, of which many are found in the neighbourhood of Mexico, in localities where, during seven months, not a millimetre of rain falls. Cacti (two *Opuntia* one *Mammillaria*, one *Cereus*) support life by economising the water which falls during the season of rain: the cuticle and the spines retain the precious moisture stored in the fleshy stems well known to all—these are, moreover, almost entirely concealed with the *Mammillaria* in the soil. All these Cacti have very long roots, which creep and extend below the surface of the soil into interstices, where they send out threads which burrow and seek in the depth of the ground for water which may have filtered thus far through. *Agave americana* (or *Magney*) is also protected by a thick cuticle, which the natives use as parchment, to be written or painted upon. *Schinus molle* (or Tree of Peru) has its leaves covered with a glossy cuticle; the roots also are very long, running over the surface of the soil, and sending down ramifications. This root is so errant, that *Schinus* is not much cultivated in gardens; it spreads over all the ground, and denudes it to the detriment of neighbouring plants. *Senecio præcox*, which is a Composite, has a straight stem nearly 5 feet high; it branches several times, and each branch is terminated by a group of flowers. These open, and the plant blooms before possessing a single leaf, whence the name of *præcox*. This is a wise economy; the plant is not obliged to furnish the very considerable amount of water required for forming flowers and leaves at the same time. The leaves are covered with a thick glazed cuticle. The soft interior, protected with a thick skin, encloses a considerable provision of water. The root is long, and scarcely goes over the ground, but forces itself as deeply as it can into the interstices of the lava where a little vegetable earth is accumulated. Compared with *S. vernus*, which grows in less dry regions, *S. præcox* is manifestly constructed to undergo privations, hence its miserable appearance. Then the *Tigapan Nettles* have leaves protected by numerous hairs, and these shield them from the sun when nestled into the fissures of the rocks. This flora is only to be noticed during the seven months of the dry season; when once the time of rain has come, an entirely new flora arises and develops, which in five months has completed its development and produced its seed; it then dies and disappears, leaving the ground to the only adaptable species capable of withstanding the ensuing drought. *Revue Scientifique*.

MARKETS.

COVENT GARDEN, MARCH 17.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

The Italian Broccoli is not so good as a few weeks ago, but the Kentish supply is just commencing. Brussels Sprouts are now coming from the south coast. Cucumbers are becoming very plentiful. Onions are a better trade, and prices have advanced. Of Rhubarb the Yorkshire consignments are the best at present. The supply of Scotch Kale and Turnip-tops will soon be exhausted.

POTATOES.

Market firm, with a further upward tendency for best samples. Present prices:—Maincrops and Saxons, 105s. to 120s.; Magnums and Bruces, 105s. to 120s.; Dunbar Maincrops, 120s. to 130s.; Blacklands, 100s. to 110s. per ton. Foreign Ware, 4s. to 5s. per bag. New Potatoes, 11s. to 20s. per cwt. John Bath, 32 and 34, Wellington Street, Covent Garden, W.C.

SEEDS.

LONDON: March 16. — Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., report a thin attendance on to-day's market, with a quiet

steady business doing. Grass and Clover-seeds show this week no important change in value. There is an abundant supply of English Red, obtainable on somewhat easier terms. Alsike, Trefoil, and Timothy keep firm. White Clover-seed is rather cheaper. For Tares and Rye there is a good inquiry. Canary-seed is unaltered, whilst in Hemp seed the tendency continues upwards. Mustard and Rape-seed are strong; but Linseed is dull. A few new Scarlet Runner Beans have just arrived. Peas, Haricots, and Lentils keep steady. The Board of Trade Returns give the imports of Clover and Grass seeds into the United Kingdom for the first two months of this year as 105,198 cwt., value £209,842, as against 86,134 cwt., value £172,438, for the corresponding period of 1897.

FRUIT AND VEGETABLES.

GLASGOW: March 18.—The following are the averages of the prices at this market during the past week:—Apples, 4d. to 8d. per lb.; Grapes, home, 2s. to 3s. do.; do., foreign, 4d. to 6d. do.; Cabbages, Spring, 6d. to 8d. per doz.; Parsnips, 4s. to 4s. 6d. per cwt.; Herbs, 1d. to 2d. per bunch; Leeks, 1s. 6d. to 3s. per dozen bunches; Mint, 9d. to 10d. per bunch; Onions, Dutch, 5s. per bag; do., Portugal, 9s. per case; Parsley, 1s. per stone; Potatoes, best, 10d. per peck; Carrots, 2s. to 3s. per bag; Artichokes, 3s. to 3s. 6d. per sieve; Cucumbers, 1s. to 1s. 2d. each; Lettuce, round, 1s. 3d. per doz.; Radishes, 1s. do.; Horseradish, 1s. 6d. to 2s. per bunch; Mushrooms, 1s. to 1s. 2d. per lb.; Beetroot, 6d. to 7d. per doz.; Brussels Sprouts, 1s. to 1s. 3d. per stone; Spinach, 3s. to 3s. 6d. do.; Rhubarb, 10s. to 18s. per cwt.; Turnips, Swedes, 1s. to 1s. 3d. per bag; do., white, 1s. per large bunch; Celery, Scotch, 9d. to 1s. 6d. per bunch; do., English, 1s. to 2s. do.; Cabbages, Red, 1s. 6d. to 2s. 6d. per dozen; Savoys, 1s. to 1s. 6d. do.; Broccoli, 2s. 6d. to 3s. do.; Greens, 5s. to 6s. per 10 dozen.

LIVERPOOL: March 16.—Average of the prices at undernoted markets:—St. John's: Potatoes, 1s. 2d. to 1s. 4d. per peck; Cucumbers, 1s. each; Grapes, English, 3s. to 4s. per lb.; do., foreign, 8d. to 1s. do.; Pine-apples, English, 4s. to 6s. each; Mushrooms, 1s. 3d. per lb. Birkenhead: Potatoes, 1s. 4d. per peck; Cucumbers, 6d. to 8d. each; Grapes, English, 2s. to 4s. per lb.; do., foreign, 8d. do.; Pine-apples, English, 5s. to 10s. each; do., foreign, 3s. to 5s. do.; Mushrooms, 1s. to 1s. 6d. per lb. North Hay: Potatoes, per cwt.: Giants, 4s. to 4s. 4d.; Main Crop, 4s. 10d. to 5s. 6d.; Bruce, 4s. 4d. to 5s.; Turnips, 6d. to 8d. per doz. bunches; Swedes; 1s. to 1s. 4d. per cwt.; Carrots, 2s. 3d. to 3s. 6d. do.; Onions, foreign, 9s. 6d. to 12s. do.; Parsley, 4d. to 6d. per dozen bunches; Cucumbers, 3s. to 5s. per dozen; Cauli-flowers, 1s. 6d. to 3s. do.; Cabbages, 6d. to 10d. do.; Celery, 6d. to 10d. do.

CORN.

AVERAGE PRICES of British Corn (per imperial qr.), for the week ending March 12, and for the corresponding period of 1897, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1897.	1898.	Difference.
	s. d.	s. d.	s. d.
Wheat	27 11	35 8	+ 7 9
Barley	22 11	27 10	+ 4 11
Oats	16 2	17 9	+ 1 7

GARDENING APPOINTMENTS.

MR. W. SUTTON, for the past five years Gardener at Hawkstone, Shropshire, as Gardener to H. J. BECKWITH, Esq., Millichope Park, Craven Arms, Salop.
MR. ROBERT BROWN, Senior, Foreman in the Gardens, Terregles, Dumfries, N.B., as Gardener to Sir EMILIUS LAURIE, Bart., of Maxwelltown House, Dumfriesshire. Mr. Brown takes up his new duties early in April.
MR. ERNEST A. HELPS, more than four years General Foreman in Lathom Park Gardens, Ormskirk, as Head Gardener to J. H. PARKIN, Esq., Sharrow Bay, Penrith, and enters on his duties April 1.

BOOKS: P. F. L. We are not acquainted with either, and cannot advise you. The prices seem high for such works.—*Perfumes and Seeds*. We do not know any books on the subject you mention. Picces's *Book on Perfumes* does not enter into detail regarding their cultivation.

CUCUMBERS, TOMATOES, GRAPES, &c.: W. C. We should suppose that the south and the west would serve your purpose best, but clever cultivators manage to obtain good crops in very unpromising localities, if the air be pure, and the water supply wholesome. We are unable to advise you further.

CUCUMBER: J. W. Leaves thin from lack of air and light, and probably extreme humidity, and just, therefore, in a condition for becoming a suitable

host for minute fungi. Syringe the plants with sulphide of potassium, at the rate of $\frac{1}{2}$ oz. to the gallon.

HYDRANGEAS: H. H. If the plants are expected to blossom early, do not shift them till they have done so, or you would thereby encourage the growth of shoots at the expense of the flower heads. Apply liquid-manure occasionally. You may repot after blooming and pruning, and endeavour to obtain early growth, and by keeping the plants in a sunny place out-of-doors or in a cold pit, ripen the same thoroughly. It is upon the perfect ripening of the new growth that flowering chiefly depends.

LAND UNDER SHADY BEECHES: A. B. It is almost waste of time and money to sow grasses in such positions unless the land be seeded annually with Italian Rye-grass. Better plants would be Periwinkle (Vinca), strong-growing Ivies, hardy Ferns, such as Scolopendrium; and in the less densely shaded parts, Snowdrops, Scillas, Crocus, and Solomon's Seal, and Saxifraga umbrosa London Pride, would succeed, mown over once or twice in the summer.

LOS ANGELES: E. Green. Advertise in *American Gardening*, or other United States of America gardening journal. It is a fine district for the Grape, Orange, and other fruits, perfume plants, &c. The climate is like that of the south of France, and would doubtless be beneficial to your health, relieving the rheumatic affection that you suffer from.

NAMES OF FRUITS: Mr. Rooper. Pear not recognised. Fairly palatable for so late a variety.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—E. B. Streptosolen Jamesoni.—S. L. Pittosporum undulatum.—H. P. Odonoglossum luteo-purpureum of the best type.—T. F. The Cyrtopodium is C. x Murillo (Boxalli x Argus). The imported Dendrobium nobile flowers are very fine indeed.—J. L., Belfast. A very good variety of Cyrtopodium hirsutissimum.—Tempus fugit. Orobanche corulea, introduced with peat—parasitic on roots.—J. R. M. Jasminum Sambac.—R. S. Saxifraga aretioides.—J. P. T. Dendrobium crystallinum.—J. Mc. 1, a very fine Cyrtopodium villosum; 2, Cologynae flaccida.—F. B. 1, Asclepias curassavica; 2, probably a seedling Cypress, but it cannot be named from the specimen sent; 3, Anthericum liniare variegatum.—G. B. 1, Erica carnea; 2, Erica mediterranea; 3, Pulmonaria officinalis; 4, Anemone coronaria, one of the double forms.—Anstie. Ghent Azalea, carnea elegans.

PANCRATIUM: Contich. Hymenocallis ovata.

SLUGS AND WOODLICE IN A FERNERY: A. J. N. Boiling water is the best remedy for woodlice, dashing it under stones, into crevices, &c. The insects propagate rapidly, and at first are very minute, but boiling water ends them by the thousand, but it must be frequently employed till it is seen that their numbers have greatly lessened. Try quick-lime or culinary salt for the slugs, applying a sprinkle at their feeding time. Many may be caught under slates raised $\frac{1}{2}$ inch from the floor.

COMMUNICATIONS RECEIVED.—T. H., the answer to your questions would take up more time and space than we can afford. We will endeavour to give you some hints next week.—W. R.—Carter & Co.—H. R., Singapore.—C. A. H., next week.—H. Corveon, Geneva.—G. C. D.—Sander & Co.—C. W. H.—J. F. H.—J. H. S.—A. R.—Dr. Christ Basle.—F. W. B.—V. Dallimore and G. B. (next week).—R. A. R.—J. A.—F. C. D., Woodville, N.S.—A. W., Ware.—S. A.—J. F. McL.—W. R.—J. Dickson & Sons.—W. R.—J. A.—H. M.—R. D.—G. G.—Expert.—W. A. S.—D. T. F.—W. B. H.—J. O'B.—G. H.—H. W. W.—E. F. H.—Goodlife.—G. B.—Constant Reader.

DIED.—On the 11th inst., at 303, Clapham Road, CHARLOTTE ELIZABETH, wife of ROBERT BRAITHWAITE, M.D., F.L.S., and second daughter of the late N. B. Ward, F.R.S.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardener's Chronicle" has, since the reduction in the price of the paper,

MORE THAN DOUBLED, and that it continues to increase weekly. Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

THE

Gardeners' Chronicle.

SATURDAY, MARCH 26, 1898.

SEEDS.

THE vitality of seeds has lately engaged the attention of botanical physiologists. Experiments have been made at Kew and elsewhere for the purpose of determining what changes, if any, take place in seeds when placed under conditions of exceptionally low or high temperatures, and the results have been surprising. Seeds which had been subjected to a temperature of -190° C. (340° F. of frost) for nearly five days were uninjured, and germinated freely when sown. Similar results followed the boiling and roasting of certain seeds for half an hour or more. It has been recorded that seeds of Poppy, Sunflower, and Parsley, when made perfectly dry, did not lose their vitality when placed in a temperature of 212° F. for forty-eight hours.

These experiments may lead to results of the greatest practical importance. They show that seeds are capable of supporting, without any loss of vitality, conditions which would be fatal not only to the plants which bore them, but to life in any form. Their condition under these extremes must be one of what is termed suspended animation; and if once this fact can be established, we may expect to find conditions in which seeds might retain their germinative power for any length of time. The germination of "Mummy-wheat" and of the Grecian refuse-seeds, which had lain dormant two or three thousand years, would then seem no longer impossibilities.

Seeds vary enormously in their provisions for retaining vitality, some perishing in a few weeks if kept at rest, whilst others have been known to grow after being kept for a century or more. What the change really is that takes place in a seed, and destroys its vegetative power, does not appear to be known. It is therefore to be hoped that the present enquiry will lead to the discovery of some means by which we can keep seeds of all kinds healthy for much longer periods than has hitherto been possible. With our present methods for the treatment and transport of seeds, failure is often experienced. Experiments might be made on such seeds as soon perish under ordinary conditions, by keeping them in a frozen condition for a lengthened period, and then sowing them. The experiments already made prove that some seeds, at any rate, were uninjured by extremes of temperature such as they never experience in a state of Nature. As an example of how useful such a discovery would be, we may cite the recent failure of a large importation of seeds of a rubber-tree intended for distribution. It is possible that the refrigerator may be turned to account by the seed-merchant with results as satisfactory as in the case of the meat and fruit merchants.

Much may, however, be done even under present methods by the grower, the harvester or collector, and packer to ensure a longer duration of seed vitality. When seeds are intended to remain dormant for a time, they should be collected only when thoroughly ripe. If known to perish soon, they should be kept in soil or some similar medium. Most kinds of seeds, however, are safest when stored in canvas-bags or paper packets, and kept in a dry place of uniform medium temperature. The hermetically-sealed method often proves disastrous.

The longevity of seeds cannot be ascertained by an examination of their shells or structure generally. Seeds may look good, and when sown fail to germinate; whilst on the other hand, seeds which are shrivelled and apparently incapable of germinating, sometimes germinate readily.

The treatment of old seeds whose germinative powers have been weakened from some cause, requires careful consideration. As a rule, seeds with hard or tough leathery shells are less liable to perish easily than those with soft or thin papery shells. Every seed has stored up within itself all the materials necessary for the development of the embryo when placed under suitable conditions, but sometimes it is enclosed in a shell so impervious to heat and moisture that it remains unquickened for a long time, and, in some cases, it is unable to germinate. The seeds of *Nelumbium* when once dry will lie dormant for several months, even when placed in warm water, but if the shell be cracked, or filed through, germination begins at once. Other hard-shelled seeds behave in the same way, and they have been known to lie unaffected by either heat or moisture for several years until released, as it were, by filing or cracking their shells. Immersion in boiling water for a few minutes by holding the pot and soil containing the seeds in a bucket, or, if large, removing them from the soil and after soaking in hot water resowing in fresh soil, will often hasten germination.

As a general rule, a higher temperature than that under which the parent plant thrives is preferable for all seeds, and the older they are the higher, in reason, should be the temperature. Heat quickens the embryo into activity and softens the wrappers of the seed. Some cultivators are of opinion that the seeds of alpine plants and indeed of all plants give better results when treated after Nature's plan in regard to heat and moisture. This would hold good were it not that the seed is often made dry, hard, or tough by the treatment it necessarily undergoes before it can be sown, and to remedy this an excess of heat above the normal is necessary. Frost is said to have the same effect on the seed-wrapper as has heat, but speaking from experience with many kinds of seeds of varying ages, I should say that old, weak seeds of doubtful vitality are much more likely to germinate under the stimulating influence of a high temperature than otherwise. Seeds of *Primula imperialis* from a very great elevation in Java germinated at Kew only when sown in a tropical temperature; and the same is true of *Ranunculus Lyalli* from the snow-clad mountains of New Zealand. The seeds of the hybrid *Disas*, raised at Kew, were sown in a temperature which would soon kill the full-grown plants. Expert growers of Persian *Cyclamen*, Chinese Primrose, tuberous *Begonia*, and many other cool-house plants, sow the seeds in a tropical temperature. Numerous instances of this character might be given. Should any fungoid mould develop about old

seeds after sowing, the soil should be saturated with a weak solution of permanganate of potash; or, if the seeds are large enough to handle, separate the bad from the good, bathe the latter in the permanganate of potash, and resow in fresh soil.

It is well to err on the side of waiting when dealing with old seeds, as I have known such to remain dormant for two years from no apparent cause, and then to germinate. W. W.

NEW OR NOTEWORTHY PLANTS.

LIVISTONA WOODFORDI, n. sp.*

THE genus *Livistona*, though by no means a large one, contains several of the best and most useful cultural Palms we have, and any addition to it must be very acceptable to those who are admirers of Fan-Palms, nor is the present new species inferior to any yet known. Its discoverer, Mr. Micholitz, describes it as being, especially a young plant, really grand. *Livistona Woodfordi*, like most species of the genus, attains to a considerable height—from 30 to 40 feet—the diameter of the stem being from 4 to 5 inches. The leaves have rather slender petioles, on which I see no thorus, but the bases are wanting in the specimens. The petioles are but a quarter of an inch through. The blade of the leaf is orbicular, 2 feet long, and about 18 inches across, split into very narrow acuminate lobes, the lower ones of which are free almost to the base; those on the apex of the leaf are split only one-fourth of the way down. The leaves sent are rather thinner than those of most *Livistonas*, but may have been taken from young plants. The spadices attain a length of 4 feet, and are unusually slender. They bear numerous panicles, with short, slender branches protruding from the mouths of the tubular brown sheaths. The flowers are unusually small, almost minute, and are sessile in small clusters of two or three on the branches of the panicles. The drupes are globose, three-eighths of an inch long, and apparently (judging from spirit specimens) bright red. They have a fleshy, fibrous pericarp, and a globose seed.

This Palm appears to be very local; only found in one island, so far as its collector has seen. Its affinity is with *L. australis*, the *Corypha australis* of many gardens; but it is even more elegant, and possesses much smaller flowers, and smaller globose fruit.

The *Livistonas* occur from India through the Malay Peninsula and Archipelago, to China and Australia, and this species extends the range into the Polynesian Islands. H. N. Ridley, *Singapur*.

KEW NOTES.

PHYTELEPHAS MACROCARPA.—A male plant of this the Ivory Nut Palm, is now in flower in the Palm-house at Kew. The female plant flowered for the first time in the same house forty years ago, and it has flowered frequently since. What little trunk it has is below ground, the elegant pinnate leaves, 20 feet long, appearing to spring from the soil. The male flower-spike is axillary, at first erect, then curving over and growing along the ground. It grew about 6 inches in length in twenty-four hours, its ultimate size being nearly 2 feet in length and $2\frac{1}{2}$ inches in diameter, somewhat flattened, and covered from base to apex with a bottle-brush-like

* *Livistona Woodfordi*, n. sp.—Palma elata ad 40 pedes alta; caulis diametro 4–5 pollicari. Folia petiolis gracilibus, $\frac{1}{2}$ pollicis crassis nec armatis (an semper?), laminis orbicularibus fissis 2 pedes longis, $1\frac{1}{2}$ pedis latis, lacinis angustis acuminatis inferne ad basin fissis, superne ad $\frac{1}{4}$ longitudinis laminae. Spadices 4 pedales elegantes, pedunculis gracilibus. Spathae tubulosae. Paniculae spadices breves, ramis minute pubescentibus brevibus ad $1\frac{1}{2}$ pollicis longes. Flores minuti sessiles. Sepala ovata obtusa imbricata. Petala minora orbicularia. Stamina 6 brevissima filamentis basibus dilatatis, antheris globoso cordatis. Carpella minutissima, stylis coherentibus. Drupa globosa rubra $\frac{3}{4}$ pollicis longa, pericarpio tenui fibroso-carnoso. Semen globosum albumine corneo, testae lamina in cavitatis intrusa. In insula Polynesiae, detexit cl. Micholitz. H. N. Ridley, *Singapur*.

arrangement of soft cream-yellow stamens, which emitted a powerful fragrance for the first two or three days, and, when shaken, a cloud of pollen was given off. Purdie, who first sent home seeds of this Palm, states that he was attracted to it by clouds of insects hovering near where it grew. It is a native of Central America and Colombia, where it grows near streams. The fruits are borne in large globular heads, and the hard seeds are largely used for making buttons, &c. As a garden Palm this is one of the handsomest, but it requires a large house for its proper display.

BAUHINIA VARIEGATA.

A large plant of this, one of the most beautiful small trees of India, is now in flower in the Palm-house at Kew. It is treated as a climber, and covers an area of about 100 square feet in the west transept. It has a thick woody stem, numerous branches and branchlets clothed with pale green leaves which vary in size, but average 6 inches in length and width, the petioles an inch long, the blade cordate at the base, the apex bilobed. The flowers are borne in short terminal or axillary racemes, and they resemble as to size, form, and colour, the flowers of a large *Pelargonium*, the five sub-regular obovate-oblong petals, each $1\frac{1}{2}$ inch long, being coloured bright rose, the lowest one streaked with crimson. According to Sir Joseph Hooker, this is an exceedingly common plant throughout India, forming a tree 20 feet high, and when covered with blossoms, which appear in March, it is, he says, a glorious object. Unfortunately it does not flower in our plant stoves, no doubt through lack of intense sunshine and a dry season to ripen the wood. A variety with pure white flowers, named *candida*, is also grown at Kew, where it flowered beautifully five years ago, when it was figured in the *Botanical Magazine*, t. 7312.

STERCULIA NEO-CALEDONICA.

The Kew example of this handsome species is again in flower in the Palm-house, where it is likely to be an attraction for several weeks, the stem showing a large number of buds. It first flowered in 1894. It is an erect, unbranched tree 10 feet high, with a stout, woody, naked stem, bearing a crown of large, palmately-lobed, dark green leaves, some 4 feet in diameter. The flowers are borne in racemes, which spring from the greater portion of the naked stem, and they are numerous, star-shaped, half an inch in diameter, their colour being brilliant orange-red. So far as I know, this is the only example of this *Sterculia* in cultivation. It is figured in the *Botanical Magazine*, t. 7382.

PLANTS OF ST. HELENA.

An interesting collection of some of the rarer plants of this island has lately been added to the Kew collection. Among them are *Commidendron robustum*, a true Composite, though known in the island as the Cabbage-tree; *Hedyotis arborea*, a near ally of *Cinchona*, and peculiar to St. Helena; *Acrostichum bifurcatum*, a pretty little form, with finely-divided leaves, suggestive of *Davallia parvula*; *A. subdiaphanum*, with dark green hart's-tongue-like fronds, markedly corrugated; *Dicksonia arborescens*, some fine stems, now growing freely. This Tree Fern is found only in St. Helena, where it forms a stem 10 feet high. The finest example of it I know in cultivation is in the Liverpool Botanic Garden. The "moss" used as packing for the stems received at Kew proved to be *Hymenophyllum capillaceum*, also endemic in St. Helena; and, so far as I know, not before introduced into English collections.

MASDEVALLIA POURBAIXII.

A healthy plant of this hybrid is now bearing half a dozen fine flowers in the Orchid-house at Kew. It was raised by a Belgian amateur, M. Eugène Pourbaix, of Mons, from M. Veitchiana and M. Shuttleworthii, the cross being effected in 1888, the first flower opening in 1893. There is an excellent coloured-plate of it in *Lindenia*, t. 387. In leaf characters it resembles M. Shuttleworthii, and in floral characters it is intermediate both as to form and colour. It may be described as one of the

handsomest of hybrid *Masdevallias*, and, judging by its behaviour at Kew, it is one of the happiest under cultivation.

DIACRIUM BICORNUTUM.

This is one of the most beautiful of all white-flowered Orchids, but it is one of the most refractory

FIG. 70.—SHOWING PORTION OF STEM OF ASPARAGUS FALCATUS (nat. size).

A flowering-shoot of this species was figured in the issue for February 26 last, p. 123.

under cultivation. At Kew, however, it has always grown and flowered exceptionally well, and there is a plant of it in flower in the Orchid-house now bearing ten spikes from a foot to 18 inches long, the average number of flowers on each being ten. It has been grown in a hot steamy house along with *Nepenthes*. Several smaller specimens are also showing flower.

EULOPHIELLA ELISABETHAE.

This is also well represented at Kew, the two plants of it which flowered so well last year being even better this. It is a strikingly handsome Orchid, its long plicate dark green arching leaves and horizontal rigid flower-spikes springing from the surface of the soil, the scapes and bracts coloured varnished crimson-brown, whilst the flowers, when open, are white. This also requires hot moist treatment, and at Kew it is grown under precisely the same conditions as the *Diacrium*.

Phaius Cooksoni, *Caladenia alba*, *Pleurothallis scapha*, *Bartholina pectinata*, and other interesting Orchids are also in flower. The last-named has a fleshy kidney-shaped leaf 1 inch in diameter, and an erect scape 5 inches high, bearing a flower 3 inches across, which is remarkable in having its purplish lower segments divided into narrow strips, and spreading horizontally, suggesting a comb. W. W.

THE CULTIVATED SPECIES OF ASPARAGUS.

(Concluded from p. 148.)

A. sarmentosus (fig. 71, p. 179).—An elegant evergreen species, which has been in cultivation on and off since Miller's time. It was re-introduced to Kew in 1887 from Grahamstown, where it grew freely in a moist situation, forming dense fox-brush-like stems with short prickles, and studded with white starry fragrant flowers, which are followed with bright scarlet pea-like berries. It grows somewhat loosely at Kew where, planted out in the Temperate-house, it has stems 4 feet high, freely branched and clothed with dark green flat leaves, $\frac{3}{4}$ inch long. It is also grown in pots and baskets for the Cape-house, and when in flower it is greatly admired. A figure of it was published in the *Gardeners' Chronicle* in 1894, which is the one here reproduced. Mr. Baker describes three varieties of it, and states that it is widely distributed in South Africa.

A. scandens.—A slender scandent species, with thin spineless stems 8 feet long, branching freely above, the branches angular, short, hair-like, not zig-zag, and bearing ternate flattened, curved dark green leaves $\frac{1}{2}$ inch long. Flowers axillary, solitary, small, white, succeeded by bright scarlet pea-like berries, containing only one seed. This plant was cultivated at Kew twenty-five years ago, and is still grown there in the conservatory, where it is an effective pillar-plant, especially when in fruit in the autumn. There is also a variety of it called *deflexus*, which is so similar to *A. crispus* (*decumbens*) as to be often taken for it. The leaves of the latter are, however, narrower, and there is also the difference in the fruit, *crispus* having an oblong six-seeded berry, whilst in *scandens* and its variety the berry is scarlet and one-seeded. The branches of the variety *deflexus* are very zig-zag. I have seen plants of it named *A. albus* and *reflexus*. A native of South Africa.

A. schoberioides.—A dwarf deciduous species, which is hardy on the rockery at Kew. It has no particular attraction, the stems being about a foot high, thin, wiry, branched above, the leaves in clusters of three or four, $\frac{1}{2}$ inch long, linear, falcate, deciduous. Flowers small, sessile on lower half of branches, succeeded by numerous small red berries. Two forms of it were introduced from Japan in 1880 by Messrs. Veitch & Sons. A longer-stemmed form of it was also introduced into the St. Petersburg Botanic Garden about the same time. There is an example of it growing in a pot in the Temperate-house at Kew.

A. Sprengeri.—As a garden plant this ranks next in value to *A. plumosus*. The Continental nurserymen grow large quantities of it for the decoration of rooms, &c. It is also becoming popular for the same purposes in this country, several market-growers now having large stocks of it. It has fleshy white tubers, from which spring numerous slender woody stems, from 2 to 6 feet long, freely branched, the branchlets forming with the flattened glossy, green, inch-long leaves, an elegant ostrich-feather-like arrangement. Flowers in racemes an inch long, small, whitish. Berry, $\frac{1}{8}$ inch in diameter. Introduced from Natal

FIG. 71.—ASPARAGUS SARMENTOSUS. (SEE P. 178.)

by Messrs. Dammann & Co., in 1890, and named by Regel in compliment to their manager. It was awarded a First-class Certificate by the Royal Horticultural Society in 1896. It has been called *A. falcatus* var. *Sprengeri*. I recently saw in an

American paper a description of a variegated form of this species "so heavily variegated with pure white as to have only a line of green on each of its small leaves, sufficient, however, to enable the plant to grow as vigorously as the type."

A. tenuifolius.—A shrubby species, in the way of *A. acutifolius*, but with longer leaves and larger berries. It is hardy in this country, the rootstock being woody and perennial, the stems annual, wiry, smooth, 3 feet high, the branches with an upward curve, the grey-green leaves linear, curved, half to 1 inch long, arranged in whorls of about twenty at close intervals along the branches. Flowers axillary, $\frac{1}{4}$ inch in diameter, white, succeeded by bright red berries as large as Cherries. A good specimen of this, when in fruit, is highly ornamental. It used to be, and may be yet, exceptionally happy in Canon Ellacombe's garden, it flowering in May, and fruiting freely. It is a native of Central France, Italy, &c.

A. trichophyllus.—A hardy species, allied to *A. verticillatus*, but with shorter thinner stems, and more rigid leaves. The stems are annual, flexuose, 3 to 6 feet long, freely branched above, with spines at the base of the branches, which are curved upwards. Leaves from $\frac{1}{2}$ to 1 inch long, stiff and subulate, arranged in clusters of from twenty to thirty. Flowers axillary, usually singly, on long pedicels, succeeded by pea-like berries. A native of Siberia and Northern China. In sheltered positions, or in a greenhouse it grows into a dense bush-like specimen. I have seen a fine example of it in the open air in the Jardin des Plantes, Paris.

A. umbellatus.—A sub-shrubby plant, which is now and then seen in cultivation, having been introduced from the Canary Islands, where it is a native, in 1828. It has slender, striated, wiry stems, copiously branched above, the branches drooping, and thickly clothed with stiff, almost spinous triquetrous leaves, $\frac{1}{2}$ inch long, and arranged in clusters of from ten to twenty. Flowers in compact umbels of about a dozen, small white, fragrant. Berry, pea-like. This plant is hardy in a sheltered position, and is worth growing for its fragrance when in bloom. It is also worth growing in pots for the greenhouse. It has been called *A. grandiflorus*.

A. verticillatus.—An old garden plant according to Miller, but rarely seen in cultivation. Canon Ellacombe speaks highly of it as a hardy garden plant, and even recommends it as a vegetable, having tried its stout, fleshy young stems and found them palatable. With him the stems grow to a height of 15 feet in May, and they are not injured by spring frosts. The rootstock is woody, and the stems $\frac{1}{2}$ inch in diameter, woody with age, smooth, armed with short hard spines at the nodes, and bearing numerous slender branches from 1 to 2 feet in length. The leaves are hair-like, from $\frac{1}{2}$ to 2 inches long, and arranged in tufts of from two to twenty. Flowers small, succeeded by bright red berries, like those of the common Asparagus. There is a fine specimen of this species in a border in the Jardin des Plantes, Paris, where the stems grow to a length of 15 feet, and fruit freely. It is a native of Persia, the Caucasus, Siberia, &c.

A. virgatus.—First described by Mr. Baker in Saunder's *Refugium*, from a plant collected in South Africa by Mr. T. Cooper. It was included among Mr. Bull's new introductions of 1879, and described by him as "a remarkably elegant feathery-looking greenhouse plant of fruticose habit, recently introduced from the Cape of Good Hope." It has a fleshy rootstock, erect fascicled stems 3 to 6 feet high, smooth, the upper half branched, the branches arching and clothed with hair-like dark green leaves $\frac{1}{2}$ to 1 inch long, arranged in tufts of three. Flowers small, white. Berries numerous, bright red, pea-like, one-seeded. In habit this is not unlike the common Asparagus. It grows vigorously either in a pot or planted out in a greenhouse.

A. comorensis (fig. 72, p. 181) has been referred to *A. plumosus*, but it is distinct from that species. It was first described and figured in the *Wiener Illustrirte Garten Zeitung*, 1888, p. 158. It resembles *A. plumosus* very closely in the form and arrangement of its frond-like branches, but it differs in its more robust habit, darker green colour, and the soft texture of its leaves. It also differs in fruit. Mr. J. G. Baker says this variety has not been botanically described, and is not a form of *plumosus* W. W.

THE CINCHONA IN INDIA.*

(Concluded from p. 162.)

COLLECTION OF BARK.—In Sikkim, the periodical crops of bark will be got from thinnings and prunings from the fourth or fifth year up to the twelfth year, when the trees will be at their best, and it is then more profitable to totally uproot, and plant on fresh land, than to allow them to remain longer in the ground. The plan originally laid down was to plant out 2400 acres, and afterwards keep up this area by uprooting 200 acres annually and planting as much; but factory demands and other circumstances often compelled modifications, although in the main the plan was adhered to till of late years, when it was found that bark for the factory could be got from Travancore and elsewhere at less than its cost to grow in Sikkim, where planting operations have consequently been restricted of late. So Sikkim is gradually becoming more of a manufacturing than a cultivating centre for the East India Cinchona industry. When the trees are uprooted the bark of the larger roots, stems, and thick branches, is collected by peeling or beating off with wooden mallets. The smaller branches and roots are peeled by pulling them smartly through between two upright sticks stuck firmly and closely together in the ground when the bark comes away in ribbons. One or two heavy and cumbersome machines have been invented for collecting this small bark, but none has answered better than the two simple sticks stuck in the ground, which reminds one of the old story of the inventor and his cabbage-cutting machine which, the inventor declared, after all its good points had been explained and praised, cut Cabbages nearly as well as an old kitchen table-knife did. The bark is at once spread out to dry either in open or heated sheds according to the weather, and when properly dried and protected from damp and rot, will remain chemically unchanged for scores, or perhaps hundreds of years. Although the total uprootal plan is the most profitable for Sikkim, it is by no means so for countries geographically better situated for the growth of Cinchonas. On the Nilgiris, for instance, where several species thrive to perfection, the usual plan of collecting is that devised by the late Mr. McIvor, the first superintendent of the Madras Government Plantations, and usually known as the stripping process. By it the half of the stem bark is taken from the standing trees in vertical strips of about an inch and a half in width, from the collar up to the lower branches, or as high as may be thought advisable. If the trees are quite healthy the bark will part from the wood, at the proper season, of course, with the greatest ease, and leave the cambium layer uninjured.

RENEWED BARK.

Immediately after the stripping, the stem is covered thickly with moss, or other soft substances, to exclude the weather. From the edges of the cuts, and all over the surface of the cambium layer, the new bark forms evenly and with marvellous rapidity. In a year, or less, the renewed bark will be as thick as the original, and the remaining strips of original bark may be taken. Afterwards there may be annual collections of renewed bark for a considerable number of years. It is a curious fact that the renewed bark is much richer than the original in quinine, and consequently more valuable—often to the extent of 25 to 50 per cent. The plan requires generous treatment of the trees in the way of manure and cultivation, as only trees in vigorous growth will stand it; but it well repays the extra expenditure. For this discovery, and many other things, the Cinchona industry is heavily indebted to Mr. McIvor, perhaps more so than to any other man. Several modifications of his stripping plan have been tried, but none has succeeded so well. Perhaps the best of them is the shaving plan of the Dutch in Java. By it the outer half of the bark, all round the stem, is removed with spoke-shaves, and the stem covered up in McIvor's way. As it is well known that the great proportion of the alkaloids is located in the outer half of the bark, and very little in the inner, it is claimed for this plan that the whole of the useful factory bark can be removed by it, and the useless left behind to carry on the life-work of the tree.

It was also supposed to be less injurious to the trees, but, according to my experience, it is quite the other way. McIvor's plan, which was in operation many years before it, no doubt suggested it to the Dutch. Coppicing was tried in Sikkim, but was a commercial failure, as by it we lost the bark from the original roots, which usually amounted to quite one third of the whole out-turn. As the coppice shoots grew, they threw out new roots for themselves and the old ones died, and their bark was lost to us for ever.

FACTORY.

After the collection of the bark its plan of disposal had to be decided. The easiest plan, which also would have been the most profitable for the plantation for many years, would have been to sell the bark in London, and buy back the manufactured sulphate of quinine. But the Government, both in India and at home, were anxious to have it worked up at the plantations, so as to save the heavy transport charges, and at the same time render India independent of other countries for her quinine supplies. The Madras plantations being the oldest, were the first to attempt local manufacture, but after some years of continual failure gave up the scheme as hopeless. Their experiments were conducted by Mr. Broughton, the quinologist to the Madras Government, who did most excellent and useful work in his

laboratory, but did not succeed so well in the factory. So his experimental factory was shut up and the bark sent for sale to London, where for many years it fetched most profitable rates. But the Bengal Government, who began their manufacturing experiments a little later than Madras, persevered till success was attained. Now Madras finds it pays better to adopt the Bengal plan of local manufacture than to ship the bark. There were numerous processes tried at the Bengal plantations, but it will suffice to give brief details of the three principal. The first, which was started in Madras, and afterwards tried in Bengal, was supposed to be the process then worked by the European makers of sulphate of quinine, who, however, gave no information on the subject, but jealously guarded their trade secrets which, of course, was perfectly legitimate and business-like, but plainly showed that no help in starting quinine making in India was to be had from them. By this plan the alkaloids were extracted from the bark by repeated hot digestion with water mixed with a little sulphuric acid, and afterwards precipitated from the acidulated liquors with milk-of-lime. The precipitate was collected on calico filters, dried, powdered and treated with strong, hot spirits of wine to dissolve out the soluble alkaloids from the insoluble sulphate of lime which formed the bulk of the precipitate. Then the alcohol, containing the alkaloids in solution, was mixed with a little dilute sulphuric acid and recovered by distillation for future use, and the remaining acidulated liquor treated in the ordinary way for the recovery of the quinine and other alkaloids. But the plan proved a miserable failure both in Madras and Bengal. It missed more than half the alkaloids, and was tedious and costly to work. This was unfortunate, as the chemicals required to work it were mostly procurable on the spot, an important consideration in a mountainous country, where carriage is difficult and expensive. Lime was found and burnt on the place; carbonate of potash was made from the ashes of *Artemisia* and other indigenous plants; and the alcohol from Indian-corn grown by the native squatters. The method of spirit-making adopted was the one in general use among the hill-tribes of the Eastern Himalayas, and differs from the ordinary process for making grain-spirit in dispensing with the malting-step. The Indian-corn is coarsely ground, and heated till soft in as much water as it will soak up; then mixed with a small quantity of powdered ferment-cake, and put into baskets lined with bracken-fronds to ferment. When sufficiently fermented, the moist mass, with a little added water, is treated in the usual way in an ordinary still. Afterwards, the weak spirit thus got is put through a rectifying still to get it up to 60° over proof, the strength required. The ferment cakes are made on the same principle as Mushroom-spawn, and consist on Rice and the fresh, fleshy roots of a rather pretty-flowering Himalayan shrub—*Polygala arilata*—pounded up together. The soft mass is made into round cakes an inch thick, and sprinkled with a little old ferment cake in powder. The cakes are then packed away loosely among Fern fronds in a warm place, and the light excluded till the ferment fungus has permeated them, when they may be dried and stored for future use. It is a matter of common belief among all the tribes that whoever makes these cakes will be ever after afflicted with sterility, so only women beyond a certain age will make them. I do not suppose there is any real foundation for this idea, but in dealing with Eastern people it is always wise to respect their little prejudices and superstitions.

The second plan to be described was a very simple one, and inexpensive to work, but unfortunately, like the last, missed a large proportion of the alkaloids. For a good many years, however, it did good, useful work, while a better was being devised. It was never used in the manufacture of sulphate of quinine, but only for making the medicine known in India as *Cinchona febrifuge*, which is a mixture of the whole of the alkaloids, both amorphous and crystallisable, found in the red bark. It is not so elegant a preparation as sulphate of quinine, but is an excellent substitute for it in malarial fevers. In fact, some of the best Indian doctors prefer it. For some years it was sold at less than quarter quinine rates, and was a great boon to poor people. In making it the powdered bark was repeatedly macerated in wooden tubs, with very dilute muriatic acid, for a few days at a time, and the resulting liquors mixed with a solution of caustic soda to precipitate the alkaloids they had dissolved out of the bark. After standing twenty-four hours, the precipitate was collected on filters, purified, dried, and powdered, which completed the operation.

The third process is the one now in operation in the East. It was started at the Bengal plantations in 1885, and at Madras a year or two later. Now it is being adopted by the Dutch in Java. It is a satisfactory process, as it completely exhausts the bark, and is not very expensive to work. The bark is reduced to an almost impalpable powder by means of disintegrators driven at a high speed by water turbines. The powder is then mixed with water, caustic soda, and shale-oil; heated by steam-coils to about 160° Fahrenheit, and kept constantly stirred by machinery for about an hour, when the stirring is stopped and the mixture allowed to rest quietly for an hour or two to let the oil—now containing the alkaloids—rise clear and bright to the top. The oil is then transferred to another vessel and thoroughly stirred up for a few minutes with sufficient dilute sulphuric acid to remove the whole of the alkaloids from it. After separation, by repose, the oil is drawn off for the next batch of bark, and the acidulated liquor, now containing the alkaloids in solution, is heated in steam-jacketed vessels, neutralised with a weak solution of caustic soda or ammonia, and set aside to cool and crystallise. To purify the crystals thus obtained they are collected, squeezed, redissolved in boiling water, digested for a few minutes with a little animal charcoal, filtered very

hot, and allowed to cool, when the sulphate of quinine crystallises out quite white and clean.

How to get the quinine at the very poorest in the outlying fever districts of Bengal at the lowest possible price, without burdening the public revenues, was an anxious question till the happy thought occurred to Sir Chas. Elliott, late Lieut.-Gov. of Bengal, to make use of the Post-office Department for this purpose. He ordered the quinine to be put up in sealed packets of 5 grains each, an ordinary dose, by jail labour, and sent to every outlying post-office in Bengal for sale at the low price per packet of 1 pice, which is the lowest coin in ordinary circulation in Bengal, and of the value of about a farthing. Not only is a stock of these packets kept at all the post-offices, but the postmen who visit the outlying hamlets have to carry them in their bags, and sell to any one who may ask for them. The postmasters and postmen get a small commission on the sale. A better or cheaper plan of distribution I cannot conceive, and the Italian Government have paid the Indian Government the compliment of adopting it for part of Italy.

Sulphate of quinine, quite equal in quality to the very best brands in the market, is now turned out by the Government at the Bengal factory alone, at the rate of about 1000 lb. a month. Not many years ago, the annual quinine indent of the Government of Bengal was less than this monthly output. Madras will soon be turning out as much as Bengal, and perhaps more. So the Government can take credit for freely accomplishing the task they set themselves when introducing the Cinchonas to India, as I trust I have proved to you without trying your patience over much.

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT GLEBELANDS, SOUTH WOODFORD.

In view of the number of clever growers who fail to get their *Phalenopsis* to thrive, it is a gratifying experience for any amateur to be able to say that his plants grow and flower perfectly. J. Gurney Fowler, Esq., may say this. His plants have been grown on in the same house from very small pieces, but they have now attained size and vigour rarely seen, and are about to produce a fine show of bloom. The *Phalenopsis* at Glebelands occupy the front stage of a rather low-roofed, warm, moist house, and are consequently tolerably close to the roof glass. A width of calico has been fastened to the inside of the roof, just over the plants, with a view to prevent drips, and this fact may have much significance in another direction. It has secured a subdued light which is favourable to the plants, and it minimises the risks attending cold winds and frosty weather. In the same house *Phaius tuberosus* is growing freely and producing flowers, and a batch of *Odontoglossum Roezlii* in bloom is in grand condition.

The commodious intermediate houses contain a fine collection of *Cattleyas* and *Laelias*, of which all the best varieties procurable have been obtained; and also some good hybrid *Cattleyas* and *Laelio Cattleyas*. The number of fine specimens of *Cattleya Dowiana*, *C. D. aurea*, and *C. Warscewiczii*, have thriven admirably; and the larger specimens of the varieties of *C. labiata* are in good condition, though some of the smaller plants, many of them pieces taken from the larger specimens of fine varieties, seem to have suffered by the protracted dull season just passed through. All are, however, sound, and apparently only requiring good weather to push vigorously into growth.

A number of fine varieties of *Cattleya Trianæi* are just passing out of bloom, also a charming white form of *Cattleya Schroderei*, with orange throat and a delicate blush hue on the front of the lip; a brilliant batch of *Laelia harpophylla*, and a few other of the lesser species.

In the centre of one of the houses is the famous plant of *Vanda (Esmeralda) Sanderiana*, for which Mr. Fowler was awarded a Gold Medal by the Royal Horticultural Society in October, 1896, when he exhibited it with 127 flowers. Last year the plant was not allowed to bear quite so many flowers; it is in good condition. Other subjects in bloom in the intermediate-houses were *Laelia cinnabarina*, the fragrant *Oncidium maculatum*, *Cœlogyne cristata alba*, &c.

In the large warm-house, with the *Vanda Sanderiana* in bloom, were some good *Dendrobium Wardianum*, *D. crassinode* and other *Dendrobiums*; a number of finely-flowered specimens of the old *Phaius grandifolius*; varieties of *Calanthe Regnierii*,

* Paper read at the monthly *conversazione* at the Horticultural Club on Tuesday, March 8, by Mr. J. A. Gamble.

and of *C. rubens*, which if rather small-flowered, is a very profuse bloomer, and follows the earlier and showier varieties; also *Saccolabium bellinum*, *Epidendrum Wallisii*, *Platyclinis glumacea*, and a few other pretty species.

In the *Cypripedium*-house a nice plant of *C. bellatulum album* is about to bloom, and in flower are a very handsome form of *C. Sargentianum*, with flowers of a peculiar yellow hue, tinged with bright dark red, the inside of the lip being very handsomely spotted; *C. × Morganiae*, *C. Argus*, *C. × Harrisianum superbum*, *C. × Godseffianum*, and *C. Lathamianum*.

The attention of Mr. Davis, the gardener at Glebelands, is not absorbed by the Orchids, but every feature of the garden is under his management.

FLORISTS' FLOWERS.

LARGE-FLOWERING PELARGONIUMS.

PLANTS which have been growing during the winter in a house the temperature of which needs only to be a few degrees above freezing-point, now

the glass, but where they can have necessary ventilation.

Plants in smaller pots that are making a free growth will need a shift, especially if they are intended for late blooming. It is a good plan to stop the main, and any strong side-shoots, and then, when they begin to break into fresh growth, to at once re-pot them, but do not give them too large a shift. It is of the first importance to see the plants do not suffer for lack of water; if they are allowed to become dry at the roots, it soon manifests itself in yellow foliage and drooping leaves. Free ventilation is necessary as soon as the plants begin to make free growth, but avoid cold draughts. Syringe the plants overhead on fine sunny mornings, and stir the surface of the soil occasionally.

Then there are the pretty Fancy Pelargoniums, the "Ladies' Pelargonium," as they have been termed. How they originated is perhaps not known for certain, but they may be regarded as the feminine of the larger-flowering varieties. The Fancy Pelargoniums are of rather softer growth than their more robust relatives, and they need a warmer and closer atmosphere. Being of a more compact growth, and more free-branching also than the large-flowered types, they are all very free bloomers, some especially so; and it appears difficult to name a more effective specimen exhibition-plant than a large finely-grown and well-flowered example of the variety *Duchess of Teck*. *R. D.*

THE BULB GARDEN.

IRIS TECTORUM.

At present a great deal of attention is being paid to the cultivation of the Californian Irises with, it is to be feared, very indifferent results. A good many of these do not appear to accommodate themselves to the conditions under which they have to be grown in this country, or are lost because we have not yet discovered the cause of their failure in our hands. Yet the admirer of this valuable genus of garden plants need not prove inconsolable, as there is wealth enough and to spare of equally beautiful Irises, also comparatively little known, but more amenable to cultivation.

Among these the Japanese *I. tectorum* may be included, as, while it does not thrive everywhere, in other gardens it is satisfactory in every respect. In China and Japan it is grown on the roofs of the houses, whence the specific name of *tectorum* or Roof Iris. The name is that of Maximowicz, which has the priority of that applied by Hance of *tomiolepha* or Miquel's *cristata* (not *cristata* of Aiton's *Hortus Kewensis*). Its introduction dates from about 1872, or 1874, and it has been figured several times, among other illustrations being that in the *Botanical Magazine*, tab. 6118, and that in the *Gardeners' Chronicle*, N. S. vi., 37. In Mr. J. G. Baker's arrangement, it belongs to the subgenus *Evansia*.

In appearance *Iris tectorum* is very attractive, and one can hardly do better than quote Mr. Baker's description of the flower as follows.—"Perianth-tube above an inch long; limb, bright lilac, 2 inches long; falls with an orbicular blade, 1½ inch broad, narrowed suddenly to a short haft, variegated with darker lilac, white at the throat, with a deeply lacinated lilac and white crest; standards also spreading, nearly as broad, plain lilac, oblong, with a short claw. Style branches an inch long; crests quadrate, serrated. Explicit as this description of the flower is, it is not possible for it to give a full impression of the delicate and soft colouring of the large and beautiful blooms. The stem is about 18 inches long, and from two to three flowers are generally produced in a spathe. The leaves are pale green, about a foot or more in length, and what is known as ensiform, and the rhizome is thick and creeping.

The Roof Iris grows very well here on the top of a low rockery facing almost due south, and protected from the north by a low wall immediately behind. In this position it has been for several years, and has never failed to bloom freely each year. It has had

FIG. 72.—*ASPARAGUS COMORENSIS*. (SEE P. 179.)

In a cooler house are a number of varieties of *C. insigne*, of which the most beautiful *C. i. Sanderæ* is in as fine health as the more robust growing kinds. In this tolerably cool lean-to house, the *Cymbidiums* thrive well, and *C. Tracynum* is represented by a very sturdy specimen. Here, too, in flower are the best forms of *Lycaste Skinneri alba*, *Odontoglossum mulus*, and a healthy batch of *Dendrobium Jamesianum*, whose flowers when grown cool last for a very considerable time.

In the *Odontoglossum*-houses in bloom are a few *O. crispum*, *O. Pescatorei*, *O. Halli*, *O. triumphans*, &c.; and a number of *O. Rossii majus*, and some *Masdevallias* and *Sophranitis grandiflora*.

require some attention. Remove all decaying and even superfluous leaves. Two-year-old plants that were given their final potting last October are becoming active, and producing shoots; and as these are sometimes numerous from the base of the centre of the plant, it is well to thin them out a little, and tie out the main shoots, so as to leave the centre of the plant as open as possible. This can be done by fastening a piece of bast round the pots just underneath the rim, and tying the branches down to it, bringing them down gently at first, so as to avoid the danger of snapping them off. There must be no neglect in the matter of watering, and the plants need to be kept scrupulously clean, and placed near

no protection, and its only enemies appear to be the slugs, which are plentiful here, and delight in eating through its young leaves, much to their disfigurement. A couple of rhizomes planted in light soil on the top of an out-house roof two or three years ago, have also grown well, but have not flowered. There they have, one is inclined to think, too little shelter so near the apex of the roof, and I purpose removing them a little lower down, where the cold northerly winds will not reach them. Although perfectly hardy, and standing without protection the severe winter of 1894-95, I am of opinion that *I. tectorum* is all the better for occasional division and replanting, either in spring, when growth begins to be made, or in autumn, soon after flowering. It increases quickly in the positions already mentioned, and it has also ripened seeds, young plants from which have not yet flowered. It is not unlikely that some variety of colour might ensue from raising this *Iris* from seeds, and hybridising with some other species would probably give some valuable garden plants, *S. Arnett*, *Carsethornby-Dumfries*, *N. B.*

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Miscellaneous Species.—Plants of the distinct *Schomburgkia tibicinis* will now need a light position in a warm-house, and a moderate amount of water. *Renanthera coccinea* should be removed from the resting-house to the warm-stove, and if any of the plants require to be shortened, the work may be done at once. *R. lmschootiana* seems to thrive best suspended from the roof of the Cattleya-house; it is now producing flower-spikes, and should be kept just moist at the root. Plants of the dwarf growing *Lælia pumila* and its varieties that have been wintered in the intermediate-house, may now be removed to the warmest end of the cool-house; they should be kept moist at all times. Brassias produce flowers both singular and interesting. Such varieties as *B. verrucosa*, *B. brachiata*, *B. Lawrenceana*, *B. antherotes*, *B. caudata*, *B. maculata*, *B. lanceana*, and *B. Circondiana* are deserving of culture. They are by no means difficult to grow, although frequently seen in poor condition. Use well-drained pots, and a compost of peat and moss. It is important to keep the plant well elevated above the rim of the pot, as the bulbs are liable to turn black and decay if in close contact with the soil. Place them in a warm shady position in the intermediate-house, and water them rather sparingly until the new roots push out, and the spikes commence to grow. Plants of the rare *Oncidium Brunleesianum* now starting to grow should be suspended at the cool end of the intermediate-house until warmer weather prevails, and watered freely until growth is completed. The pretty yellow-flowered *Oncidium cheiroporum* should be afforded fresh potting material if necessary, and suspend the plants from the roof of the Odontoglossum-house. Exceptional care is necessary in watering this plant, as the young growths are very liable to damp off if water lodge in them. *O. olivaceum Lawrenceanum* should be suspended at the warmest end of the cool-house, where their flowers will open perfectly. *Oncidium tigrinum* now at rest in this house, should be kept rather on the dry side, but not sufficiently to cause shivelling. *Disa grandiflora*, *D. Kewensis*, *D. Premier*, *D. racemosa*, *D. Langleyensis*, *D. Veitchii*, &c., now growing freely, may be given an abundance of water.

Temperatures.—Now that a large number of Orchids are beginning to grow, it will be advisable to slightly raise the temperature in the houses. The night temperature of the East Indian or hottest house may be maintained at 65°, and the day temperature of same at 70°, but a rise of several degrees more by sun-heat will be beneficial. During the middle of the day admit air whenever practicable; close the ventilators early in the afternoon, at the same time thoroughly damp the floors, stages, &c. The night temperature of the Cattleya-house should not fall below 60°, nor the intermediate-house below 55°, and the day temperature may rise from 5° to 10° above these figures, with a moderate quantity of air when the weather is mild. The Mexican division should also be kept at about 60° by night, rising in the daytime by sun-heat to 70° or 80°, with plenty of ventilation. Shut these houses up early in the afternoon with sun-heat, and thoroughly moisten the floors, &c. In the evening a few of the lower ventilators may again be partially opened, but not so much as to rapidly lower

the inside temperatures. The *Odontoglossum* or cool-house may be kept up to 50° at night, and a trifle higher, with plenty of ventilation, if the weather be mild. Fire-heat, especially in this division, should always be used as little as possible. A damping down both morning and afternoon will be sufficient for the present. When damping in the afternoon my practice is to close all the top ventilators, leaving the bottom ones wide open, and in the evening, if the external air is about 50°, the top lights are slightly opened again, and allowed to remain so all night, if the weather is likely to remain mild.

THE HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Grafting.—By means of grafting, healthy, vigorous Apple and Pear trees, of inferior quality as regards their fruits, or which are shy-bearing, may in a few years be changed to the choicest varieties. Many of the small varieties of the Apple are not much valued since the introduction of large fine-flavoured ones, and the trees of the former may at this season be headed-back and re-grafted, the method known as rind-grafting being employed if the trees are of large size, but the sap must be flowing freely before this kind of grafting can be done safely and successfully, otherwise the bark adheres to the wood, and cannot be easily detached. Cleft or wedge-grafting is the more suitable method; from ten to thirty, or a greater number of branches, may be grafted on one tree. First cut off the tops to a point where the wood is about 4 inches or less in diameter; if it is only 2 inches it will be better, provided the greater part of the grafts come on parts within 12 feet of the ground—if beyond this, the trees eventually get too tall for convenience of gathering the fruit. All the lateral branches below the cuts should be left intact for the first season at least. Some gardeners cut the trees back several months before grafting is performed, but this is unnecessary, and if any trees have been thus treated, two inches more of the wood must be cut off previous to grafting in order to have living healthy wood to work upon. If the cuttings to be used as scions have been removed as advised, they will be in an inactive but plump and sappy state. Place the butt-ends of the cuttings in a water-can provided with an inch of water while working. Clay to be used for covering the point of union must be got in readiness a day or two beforehand and placed under cover. It should be of the most adhesive kind, or it will crumble to pieces and fall from the trees; and if stones are present in it these must be removed by hand-picking. Having done this, take fresh cow or bullock-dung one-third, and a little soft chaff, and mix the whole together with water by means of a spade till it be of the consistency of putty when fit for use. If but few grafts have to be inserted, cold grafting-wax such as Mastic l'homme Lefort, or one that is home-made, may be used instead of clay. Having cut the stock back as directed, make a downward slit in the bark for a length of 2½ inches, as deep as the wood; lift the bark, and slip in the prepared scion. A scion may be 6 inches long, with sloping cut made at its butt-end 2½ inches long. If the branch of the stock is 4 inches in diameter, three scions may be inserted at equal distances round the end; those 2 inches in diameter will take two on opposite sides, and 1 inch branches one scion. A modification of this method consists of carrying a strip of bark from the scion across the top of the stock and into a slit made on the opposite side. It is a method that gives much trouble, and is not necessary to ensure full union. When a scion is inserted, it must forthwith be bound round moderately tight with raffia or soft bast, and be clayed or waxed at once, or the two adjacent surfaces of the rind will become dry, and the union of the two hindered or prevented. In claying, make the central part an inch thick all round, tapering it off at both ends. Clay is easier to manipulate if the hands be moistened occasionally. Should drying winds prevail, or if there is doubt as to the clay adhering to the bark, wrap some freshly-gathered moss over all, and tie it on. Strong-growing Apples make the best grafts for large trees, and fruit is obtained much quicker in this way than by planting young trees. The grafting of Pears on walls or in the open, and Pears on the Pear-stock and double grafted, is similarly performed. Plums and sweet Cherries are likewise grafted at the end of the month. It is always advisable to wait, provided, of course, the cuttings have been taken some few weeks, and kept fresh and moist in a cold situation, till the stock is on the move, before proceeding to graft.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Summer and autumn-flowering Chrysanthemums.—For affording nice effects in large beds, and flowers for cutting, these plants are of no small use. Greatly improved of recent years in colour and habit, they can now be obtained in numerous varieties that flower from the month of July till late in the autumn, when they are cut off by frost. Now is the time to plant.

Iris.—For planting in borders and as edgings by the sides of woodland walks of lakes and streams, than *Iris*es, of various species of exquisite colouring, there are no more suitable plants. *Iris*es when planted alone or in company with *Narcissus*, *Bluebells*, *Primroses*, &c., that are purchased at small cost and readily raised, which need but little attention beyond keeping the ground free from weeds, always impart a pleasing effect when in bloom, and they are not unsightly in the flowerless state.

Pentstemons.—If seeds of this old inhabitant of the garden, that is rapidly gaining in popularity, be sown this month in heat, and the seedlings grown on without check, and planted out in the month of May, flowers may be looked for from the middle of July to the end of September. The plant delights in sunshine but is not fastidious as to soil, although well-tilled and manured soils afford the best results.

Potentillas deserve to be more commonly grown in beds and borders, the foliage being pretty, and not unlike that of the Strawberry, and the flower neat in appearance and bright in colour. Plants raised from seed sown last year may now be set out where they are to flower, allowing 1½ foot from plant to plant, or from neighbouring plants.

Salpiglossis.—Seeds should be sown in heat at once; and as soon as the seedlings may be handled prick them out, and they will be ready to put out in the beds about the end of May. If the beds are sufficiently manured, the plants will make a beautiful effect in the flower garden throughout the summer and early autumn months. The flowers are very desirable for cutting also, some of them having beautiful tints and refined pencilling.

Salvia patens.—Tubers which have been rested during the winter should now be potted, or put into boxes and placed in warmth. If it is wished to increase the stock, take short-jointed cuttings as soon as they are obtainable, and insert them in sand, or sandy soil, in the propagating-pit. The cuttings are best placed around 5-inch pots.

Tigridias.—The flowers of these, although of short duration, are exceedingly beautiful, the colours being creamy-white and chestnut red, purple and lilac, scarlet, rose, and orange, and orange spotted on a scarlet ground. When seen in the full glare of a summer's sun, the colours are very vivid, and the blotches and pencillings so varied, that they are well worthy of culture. Plant in good sandy loam in a sunny place.

General Work.—The mowing-machine will generally be in constant use, taking the precaution not to use it before the land has been well swept and heavily rolled. Trees and shrubs newly planted will need copious applications of water, and an occasional wetting with the garden-engine, doing this last late in the day. Let no weeds remain long in any border or flower-bed, whether occupied or vacant, but hoe and hand-weed diligently. Sow Sweet Peas, and still continue to plant out *Violas* and *Pansies*; put beds and borders in readiness for sowing seeds of annuals early next month. Afford bedding *Pelargoniums* and *Calceolarias* the fullest ventilation in mild weather, but do not check growth by the admission of cold air. Prick out seedling bedding plants, and continue the repotting before crowding spoils them, of *Hollyhocks* and tuberous-rooted *Begonias*. If the *Begonia* seed was sown early in the year, the seedlings will demand unremitting attention in the matter of pricking out, potting them into thumbs and 60's, and bringing these on in an intermediate-house temperature, and in such a manner that drawing cannot take place.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

Celery.—Any of the white and pink varieties may now be sown on a mild hotbed thinly, or in seed-pans and boxes, placing the pans and boxes in a temperature of 50°, affording shade from strong sunshine till germination takes place, when full light and air in amount in accordance with the weather should be admitted. When the seedlings are large enough to be conveniently handled, prick them out 4 inches

apart in a cold frame in a mixture of one-half rich soil and one-half leaf-soil, and spent Mushroom-dung, placed above a shallow layer of manure 3 to 4 inches thick. When pricked out afford water with a fine rose-can, and syringe the plants when closing the frame in the evening till complete establishment has taken place. Afterwards afford air freely, and remove the lights entirely on warm showery days. A sowing of any of the red varieties for winter and spring use may be made in about ten days after the above sowing. The best white Celeries are, Incomparable Dwarf White, and Sandringham Dwarf White; the best pinks, Veitch's Early Rose, and Ivory's Nonsuch Pink; of reds, which are mostly very hardy, there are Major Clarke's, Standard Bearer, and Williams' Matchless. Where Celery is in request a sowing may now be made in the manner described, and the plants treated in the same manner as Celery in the early stages.

Cucumbers in Frames.—Seeds may be sown singly in 60's of Rochford's Market Favourite, Lockie's Perfection, Telegraph, or Tender-and-True. When a true leaf or two show repot in rich mellow loam and leaf-soil, in equal parts, when they will be ready to plant out on hot-beds made up for frames, or in a brick-pit with hot water for top-heat. If a frame hot-bed, let it be made 1 foot larger than the box on all sides, and at the least 3 feet high at the front and $\frac{1}{2}$ -foot more at the back. Let the materials consist of equal parts stable-dung and Beech or Oak leaves, and when the heat becomes steady at 80° put on the frame and make a hill or bed under each light of loam and rotten dung or leaf soil in equal proportions. The bed should not be less than 9 inches deep, or the hillock less than 12 inches.

Sorrel.—The old stools, if the stock of plants needs replanting, should be taken up with a spade and divided, planting the rooted bits in rows, 12 inches apart and 6 inches from plant to plant, affording water to settle the soil, and a mulch of spent manure between the rows. The flower-stalks should be cut off as fast as they appear during the season. Seeds of Sorrel of a broad leaved variety may be sown at this season in drills 12 inches apart and $\frac{1}{2}$ -inch deep, and the plants thinned out to 6 inches apart. One-year-old plants are more productive of leaves than older ones.

Scorzonera.—This vegetable requires a piece of ground which has been deeply dug or trenched; and the seed is usually sown in drills drawn at a distance of 15 inches apart, 1 inch deep. Two or three hundred well-grown roots suffice for the needs of most families. Salsafy is a similar kind of crop, and needs the same sort of treatment.

Turnips, Potatos, and Spinach.—Make another sowing of seeds of white Turnips, as Snowball, or other quick growing variety, and likewise of Spinach in larger breadths than earlier in the year, and protect the early sowings from frost and seed-eating birds. Plant early and second early Potatos on warm borders and in the open quarters of the kitchen garden.

Forcing Vegetables.—Let the early vegetables in frames and pits have all needful attention in the matter of airing, watering, thinning, &c., being careful to guard against giving any check to growth; and make more hotbeds for salading and vegetables if necessary.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Grape Vines.—Those Vines that are carrying Grapes which are at the final stage of development and colouring, should be forced till the fruit is ripe, by employing a warmth at night of 65° to 68°, and by day of 75°, by the heating apparatus, allowing the day warmth to rise to 85° during the hours of sunshine. As ventilation conduces to good colouring, air should be admitted, mostly by the top-sashes, &c., in mild sunny weather, and with much caution owing to the extremely changeable nature of spring weather. Damping down must be done several times a day according to the stage of colouring and the state of the weather, always endeavouring to maintain a genial state of the air in the house. The doing of this will tend to keep red-spider in check. During the early stages damp the surface of the border, and the paths, walls, &c., once to three times a day, according to the amount of sunshine or lack of it; less often in dull weather; during the second stage, twice a day; and in the last stage, when the fruit is nearly ripe, once on fine days only. Vines with Grapes at their full size, or approaching that stage, require more water at the

root than at any other time, it is then that manure is of the greatest use, to pot Vines or permanently planted ones. In the case of pot Vines an examination of the soil should be made every day, and no approach to dryness permitted. Keep a sharp look-out for red-spider on the leaves of both potted and planted out Vines, and if any are found sponge the leaves with soap-suds, in which soft-soap at the rate of 2 oz. to the gallon of water is dissolved. Should it appear to such an extent as to be likely to cause injury before the fruit is ripe, paint the heating apparatus with flowers-of-sulphur and lime, and raise the temperature of the vinery to 85° or 90° at night for a short period on three successive nights, taking care that the pipes are not heated so much as to cause injury to the leaves; and in order to lessen the risk, ventilate the vinery freely the previous afternoon, so as to dry up all moisture on the leaves of the Vines. In order to use sulphur safely, the Grapes should be in a forward state, otherwise there is a risk of causing rust.

Vines started in the Month of January.—The bunches on these Vines will require to be reduced in number, and the berries thinned when they have attained the size of Radish-seeds, following out generally previous instructions concerning Vines at this stage. The thinning of the bunches differs according to the variety, attention having to be paid to the general shape of the bunch and the size to which the berries attain. Compact bunches, such as those of Muscat of Alexandria, Mrs. Pince, and Madresfield Court require severer thinning than those of Black Hamburgh and Foster's Seedling.

Vines in Bloom.—In order to favour the setting, let there be enough artificial heat by day, and as much ventilation as the weather permits with safety for Hamburghs and other free-setting varieties. The internal warmth may on sunless days rise to 75°, and for shy setters to 80° on sunless days, or during periods of sunshine 6° to 10° higher than these figures are permissible. On fine days, one damping down in the afternoon will suffice till the flowering stage is past.

Vines at a Later Stage.—The strong shoots at this season are very brittle, and tying down has to be done with care, going over the shoots several times, bringing them down a little each time till they reach the trellis, and using for this purpose broad strips of bast. It is carried on more safely in the middle part of bright days, when the shoots flag a little, than at other times. Main laterals carrying fruit, stop two joints beyond the bunch; and those required to run on to fill up bare spaces should not be stopped at all—at least, for the present.

THE APIARY.

By EXPERT.

Starved Bees.—It would be difficult to name a more annoying discovery to a bee-keeper than to find on some fine morning in March or April, a strong colony of bees—strong and prospering in everything save stores—dead from famine. Yet this is not so uncommon an occurrence as many suppose when bees are in thoughtless or careless hands, and it should render it unnecessary for us to do more than mention it in order to impress on readers a caution as regards the risk mentioned above. Therefore, where any uncertainty exists, move the quilts far enough back to expose the outside frame on one side of the hive. Raise the comb as high as will enable you to examine its food contents, and do the same with the outer comb on the opposite side, and if between the two there are less than three or four pounds of stores, lift out both frames, carry them indoors, and, first laying the frame of comb in a dish, pour into the cells a pint at least of good warm syrup made fairly thick. Care is needed in filling the cells with the syrup, but it can be done by holding the vessel high up and letting the liquor fall in a thin stream. Replace the combs when filled, preferably at night-fall, or when bees have done flying for the day. A week or so later give syrup-food in the ordinary bottle-feeder.

Queenless Stocks.—The month of March being the natural season of the year when bees in all healthy colonies are impelled to join in the now rapidly increasing work of brood-rearing, stocks which from any cause have been rendered queenless will at this season become restless and unsettled. They apparently feel that something is wrong, as a child does when "mother is out." In fact, the bees of some queenless hives, being themselves motherless, occasionally get so disheartened and dissatisfied with the home that they desert it in a body. An exodus of this kind is usually termed a hunger swarm, though it not seldom happens that plenty of food is left

behind in the deserted hive. At times, too, even when no departure is resolved upon, queenless bees at this season are often noticed to be acting differently to those of prospering colonies. They become uneasy, running or flying about the hive entrance after normal stocks have ceased work for the day. Sometimes during working hours an odd bee will be seen hurrying in with just a mite of pollen on its legs, as if desperately trying to show how conscious it is of the work that should be making progress in March. Some lots, again, will show themselves to be queenless by the listless way in which they disport themselves, compared with those of neighbouring colonies, and this condition is occasionally accompanied by dysenteric symptoms, shown in the specking of flight-boards, owing to the abnormal conditions which surround queenless bees. In all these cases the only needful thing to do just now is trying to keep the bees in good heart by giving a little warm syrup occasionally until the time comes—three or four weeks hence—when they may be united to such other stocks as need bees to assist in keeping warm the daily increasing breadth of brood now being reared.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Chrysanthemums.—The plants should be now making good progress, and they must not be stinted in the matter of pots, as once root-bound they make slow headway. Varieties differ much in manner of growth, and the stronger growers require necessarily earlier repotting than those that are weak growers. It is, therefore, necessary to pot those that are in need of a shift into larger pots, which a very slight examination will suffice to show. Plants intended to form bushes, should have the points of the leading shoots pinched in order to make them break freely. The soil for this shift should be rich, and consist of good loam with some leaf-mould, sand, and a sprinkling of bone-meal and wood-ashes. Let these be well mixed together, but not sifted, and placed in the pots very firmly—rammed, in fact, if the soil be not too moist, plenty of space being left for affording water, and good drainage provided. Place the repotted plants in a cold pit or frame near the glass, affording air when the weather is not actually frosty, but avoiding cold draughts. An occasional fumigation will kill greenfly, that sometimes infests these plants whilst they are under glass. The plants should receive no water for two or three days after the repotting, but merely a good damping overhead daily.

Shading.—Most of the inmates of the stove will need protection from the direct rays of the sun from this time onwards, especially those that have been repotted. A slight shade on the greenhouse during the warmest part of the day will tend to lengthen the flowering period of the plants therein.

Propagation, &c.—Seedlings and cuttings must be potted, single or otherwise, before they spoil from over-crowding, or damp-off, and only a slight delay in carrying out this operation may end in serious loss. Batches of plants should still be brought to the flowering stage in gentle heat; but taken to a cooler place to expand their blossoms. Plants of Azalea mollis, as they go out of flower, may have ungainly shoots cut back, and the weak ones removed, and be placed in gentle heat to make their growth, and after that is made, gradually harden them off, and stand out-of-doors in May.

Seed-sowing.—Let pots, pans, and boxes, be got in readiness for sowing the seeds of a variety of subjects that must be raised at this season. Let every pot, &c., be well drained and clean, and sift the soil that is to be used, usually a mixture of loam, leaf-mould, and sand, and place the smaller sifting over the crocks to the depth of 2 or more inches, according to the nature and requirements of the seed, and the seed-pots should be filled to within half an inch of the rim, the soil being pressed down firmly with the hand, and made level and smooth. Before sowing, let the soil be afforded a thorough application of water, leaving the sowing to be done the next day. In the case of very minute seeds, no covering of soil or sand is needed, but when the mould is getting dry sink the pot, &c., in a vessel of warm water till water appears on the surface, or use the finest rose on the spout. Some seeds need no further warmth than that of the greenhouse, others must be raised in hotbeds more or less hot, and all should be carefully shaded, either separately with sheets of brown or oiled paper, or collectively with mats, &c. No seed-pot should be placed in proximity to the heating apparatus, or in a draught. Further directions will be given concerning seedlings in a future Calendar.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

MEETINGS.

SATURDAY, MARCH 26—Roy. Bot. Soc. Gen. Meet.
TUESDAY, MARCH 29—Spring Show of Shropshire Hort. Society.
Exhibition of Royal Hort. Soc. of Southampton (two days).
WEDNESDAY, MARCH 30—Royal Bot. Soc. Spring Show at Regent's Park.

SALES.

MONDAY, MARCH 28—Roses, Stove and Greenhouse Plants, Begonias, Tuberoses, &c., at Protheroe & Morris' Rooms.
TUESDAY, MARCH 29—Hardy Perennials, Japanese Iris, Roses, Carnations, &c., at Protheroe & Morris' Rooms.
THURSDAY, MARCH 31—Japanese Lilies, Palms, Gladioli, Begonias, Tuberoses, &c., at Protheroe & Morris' Rooms.
FRIDAY, APRIL 1—Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—44.9°.

ACTUAL TEMPERATURES:—

LONDON.—March 23 (6 P.M.): Max., 50°; Min., 36°.
PROVINCES.—March 23 (6 P.M.): Max., 51°, Scilly;
Min., 38°, Aberdeen.
Cold winds; light frosts; rain and sleet.

The Abuse of Manure.

THE time was, and that not so very long ago, when the statement that a given plant-disease was caused by a fungus, was considered by the horticulturist as nothing short of ridiculous, and a combination of sympathy and incredulity might often be detected in the face of the recipient of such information; this was so, so late as the time of "M. J. B.," the famous initials in these columns of the Rev. M. J. BERKELEY. At the present day the reverse is the case, and those engaged in the cultivation of plants are inclined to attribute every failure in promoting successful culture to the baneful influence of some fungus. After the truth had once been realised, the rush to the opposite extreme was just what, from analogy in other matters, would have been predicted. It now remains for the gardener, without becoming an expert mycologist, to familiarise himself with the broad principles relating to the habit and mode of life of parasitic fungi, to an extent that will enable him to determine with a fair amount of accuracy the symptoms of fungous disease; to know how to ameliorate it to guard against its spreading to other plants; and finally, to express in an intelligible manner the symptoms exhibited, when asking the advice of a specialist.

For several years past, numerous examples of diseased roots have been received for examination, and in almost every instance a fungus was supposed by the sender to be the cause of the disease. The symptoms were in all instances identical, the rootlets being completely destroyed, and the remainder of the root waterlogged, and brown in colour. Roses, Vines, and Strawberries, formed a considerable percentage of the plants examined, microscopic examination of cultures of the diseased

roots proved the entire absence of a parasitic fungus in every instance. As usual, the plants were said to have been cultivated in the most expert manner, implying that no possible blame could attach to the cultivator; heavy mulching practice, and followed by the best of results for one or two seasons, and just at the time when hope for the future seemed assured, the plants died, and without any apparent reason. Suspecting manure to be directly or indirectly the cause of the mischief, the following experiment was carried out by Mr. MASSEE.

A row of eight bush Roses of about equal size, and apparently quite healthy, was selected for experiment. The soil round each of four of the bushes was covered for a distance of 18 inches from the stem with a thick layer of stable-manure in the spring, the manure being covered with a thin layer of soil for appearance sake, and also to prevent loss of fertilising material from the manure. The four remaining bushes were left without manure placed over the roots, but were supplied with liquid-manure obtained from the same quantity of manure used in dressing the ground round the other four bushes.

During the first season the quantity and quality of bloom produced by the four bushes that had been manured round the roots, was most decidedly better than in the case of the trees supplied with liquid-manure. The same process was repeated the second spring: the first result was that there was no appreciable difference in the number of flowers on the differently-treated bushes; the second result manifested itself the following spring by the untimely death of the four trees treated with manure on the ground round the roots. Strawberry plants were killed by similar means.
